DECOMPOSITIONS OF AN ABELIAN SURFACE AND QUADRATIC FORMS

by Shouhei MA

Abstract. — When a complex Abelian surface can be decomposed into a product of two elliptic curves, how many decompositions does the Abelian surface admit? We provide arithmetic formulae for the number of such decompositions.

Résumé. — Quand une surface abélienne complexe admet une décomposition en produit de deux courbes elliptiques, combien y a-t-il de telles décompositions possibles ? Nous donnons des formules arithmétiques pour le nombre de telles décompositions.

1. Introduction and main results

Throughout this paper, an Abelian surface means a complex Abelian surface.

Let $A$ be an Abelian surface which can be decomposed into a product of two elliptic curves. In general, the choice of a decomposition of $A$ is not unique even up to isomorphism. In the present paper we study the number of decompositions of $A$. For this problem, there are pioneering works of Hayashida [5] and Shioda-Mitani [13]: Let $\rho(A)$ be the Picard number of $A$ and let $T_A$ be the transcendental lattice of $A$, which is the orthogonal complement of the Néron-Severi lattice in $H^2(A,\mathbb{Z})$. When $\rho(A) = 4$ and $T_A$ is primitive as an even lattice, Shioda and Mitani, with the cooperation of Hirzebruch, expressed the number of decompositions of $A$ in terms of the class number of a certain imaginary quadratic order determined by $A$. On the other hand, Hayashida calculated the number of decompositions when $\rho(A) = 3$, in connection with the number of principal polarizations.

Keywords: Abelian surface, elliptic curve, binary quadratic form.

Math. classification: 14K02, 14H52, 11E16.
It is natural to expect counting formulae for the decompositions for all decomposable Abelian surfaces, which complete the works of Hayashida and Shioda-Mitani. The purpose of this paper is to give such counting formulae uniformly by a lattice-theoretic method. Firstly we give precise definitions.

**Definition 1.1.** — Let $A$ be an Abelian surface.

1. A *decomposition* of $A$ is an ordered pair $(E_1, E_2)$ of elliptic curves in $A$ such that the natural homomorphism $E_1 \times E_2 \rightarrow A$ is an isomorphism. The Abelian surface $A$ is *decomposable* if there exists a decomposition of $A$.

2. Two decompositions $(E_1, E_2)$ and $(F_1, F_2)$ of $A$ are strictly isomorphic if $E_1 \cong F_1$ and $E_2 \cong F_2$, or equivalently, if there exists an automorphism $f$ of $A$ such that $f(E_i) = F_i$. Two decompositions $(E_1, E_2)$ and $(F_1, F_2)$ of $A$ are isomorphic if $(E_1, E_2)$ is strictly isomorphic to $(F_1, F_2)$ or to $(F_2, F_1)$.

There are known several criterions for an Abelian surface to be decomposable. For example, Abelian surfaces with Picard number 4 are always decomposable [13]. Ruppert [11] gave a criterion in terms of the period matrix.

Let $\text{Dec}(A)$ (resp. $\tilde{\text{Dec}}(A)$) be the set of isomorphism (resp. strict isomorphism) classes of decompositions of $A$. We put

$$
\delta(A) = |\text{Dec}(A)| \quad \text{and} \quad \tilde{\delta}(A) = |\tilde{\text{Dec}}(A)|.
$$

The number $\delta(A)$ is regarded as the number of decompositions of $A$, while $\tilde{\delta}(A)$ is considered as the number of decompositions counted with multiplicity. If we define

$$
\delta_0(A) = \left| \{E: \text{elliptic curve}, \ E \times E \cong A\} / \cong \right|,
$$

then an obvious relation

$$
\tilde{\delta}(A) = 2\delta(A) - \delta_0(A)
$$

holds. Hence the knowledge of $\tilde{\delta}(A)$ in addition to that of $\delta(A)$ would enable us to study the decompositions of $A$ more closely.

We shall express the numbers $\delta(A)$ and $\tilde{\delta}(A)$ in terms of the arithmetic of the transcendental lattice $T_A$. Let $\mathcal{G}(T_A)$ be the genus of the lattice $T_A$. For an even lattice $T$ let $D_T$ be the discriminant form of $T$, which is a finite quadratic form associated to $T$. We have a natural homomorphism $O(T) \rightarrow O(D_T)$ between the isometry groups. For a natural number $n > 1$, let $\tau(n)$ be the number of the prime divisors of $n$. We put $\tau(1) = 1$. Our formula for $\delta(A)$ is stated as follows.
Theorem 1.2. — Let $A$ be a decomposable Abelian surface. Then $2 \leq \rho(A) \leq 4$ and the decomposition number $\delta(A)$ is given as follows.

1. When $\rho(A) = 2$, one has $\delta(A) = 1$.
2. When $\rho(A) = 3$, one has $\delta(A) = 2^{\tau(N)-1}$ where $2N = -\det(T_A)$.
3. When $\rho(A) = 4$ and $T_A \not\simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}$, $\begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$, $n > 1$, one has

$$\delta(A) = \sum_{T \in \mathcal{G}(T_A)} |O(D_T)/O(T)|.$$

4. When $\rho(A) = 4$ and $T_A \simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}$ or $\begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$, $n > 1$, one has

$$\delta(A) = \begin{cases} (2^{-4} + 2^{-\tau(n)-3}) \cdot |O(D_{T_A})| & \text{if } T_A \simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}, \\ 3^{-2} \cdot (2^{-2} + 2^{-\tau(n)}) \cdot |O(D_{T_A})| & \text{if } T_A \simeq \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}, n: \text{odd}, \\ 3^{-2} \cdot (2^{-2} + 2^{-\tau(n)}) \cdot |O(D_{T_A})| & \text{if } T_A \simeq \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}, n: \text{even}. \end{cases}$$

On the other hand, the number $\tilde{\delta}(A)$ is expressed in slightly different way (in the case of $\rho(A) = 4$). The set of proper equivalence classes of oriented lattices belonging to the genus of $T_A$ is denoted by $\tilde{\mathcal{G}}(T_A)$.

Theorem 1.3. — Let $A$ be a decomposable Abelian surface. The strict decomposition number $\tilde{\delta}(A)$ is given as follows.

1. If $\rho(A) = 2$, then $\tilde{\delta}(A) = 2$.
2. If $\rho(A) = 3$, then

$$\tilde{\delta}(A) = \begin{cases} 1, & N = 1, \\ 2^{\tau(N)}, & N > 1, \end{cases}$$

where $2N = -\det(T_A)$.

3. If $\rho(A) = 4$ and $T_A \not\simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}$, $\begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$, $n > 1$, then

$$\tilde{\delta}(A) = 2^{-1} \cdot |\tilde{\mathcal{G}}(T_A)| \cdot |O(D_{T_A})|.$$

4. If $\rho(A) = 4$ and $T_A \simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}$ or $\begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$, $n > 1$, then $\tilde{\delta}(A) = 2\delta(A)$.

The number $|O(D_{T_A})|$ appearing in the case of $\rho(A) = 4$ will be calculated explicitly in Section 6. On the other hand, the numbers $|\tilde{\mathcal{G}}(T_A)|$ and
$|\mathcal{G}(T_A)|$ are rather deep and classical quantities. The reader may consult to [4] for the calculations of these quantities.

When $\rho(A) = 4$ and $T_A$ is primitive as an even lattice, we have two types of formulae for $\delta(A)$ (or for $\tilde{\delta}(A)$): Shioda and Mitani’s ideal-theoretic formula (see Theorem 5.10) and our lattice-theoretic formula. These two formulae are unified by the classical relation between primitive binary forms and quadratic fields. In particular, the comparison of two formulae will lead to an expression of the number of genera in a class group in terms of the discriminant form (Corollary 5.11).

The counting formula in the case of $\rho(A) = 3$ is known to Hayashida [5], who calculated $\delta(A)$ as the number of reducible principal polarizations. The number $N$ is defined in a different way in [5]. Given a decomposition $(E_1, E_2)$ of $A$ with $\rho(A) = 3$, we will determine explicitly all other members of $\text{Dec}(A)$ from $(E_1, E_2)$.

The rest of the paper is organized as follows. In Sect.3, we prove general formulae for $\delta(A)$ and $\tilde{\delta}(A)$. Here Shioda’s Torelli theorem for Abelian surfaces [12] and the technique of discriminant form developed by Nikulin [10] are applied. These weak formulae will be analyzed in more detail for each Picard number. The case of Picard number 2 is well-known, and can also be derived immediately from the weak formula. The case of Picard number 3 is treated in Sect.4, and the case of Picard number 4 is studied in Sect.5. In Sect.6 we will calculate the order of the isometry group $O(D_L)$ for a rank 2 even lattice $L$. This part is purely algebraic and may be read independently.

2. Conventions

Let $A$ be an Abelian surface. The Néron-Severi (resp. transcendental) lattice of $A$ is denoted by $NS_A$ (resp. $T_A$). The Picard number of $A$ is denoted by $\rho(A)$. For a curve $C \subset A$ its class in $NS_A$ is written as $[C]$. The positive cone $C^+_A$ of $A$ is the connected component of the open set \( \{ x \in NS_A \otimes \mathbb{R}, \langle x, x \rangle > 0 \} \) containing the ample classes. The group of Hodge isometries of $T_A$, i.e., isometries of $T_A$ which preserve $H^{2,0}(A)$ in $T_A \otimes \mathbb{C}$, is denoted by $O_{\text{Hodge}}(T_A)$.

Let $L$ be an even lattice, i.e., a free $\mathbb{Z}$-module of finite rank equipped with a non-degenerate integral symmetric bilinear form $(,)$ satisfying $(l,l) \in 2\mathbb{Z}$ for all $l \in L$. The isometry group of $L$ is denoted by $O(L)$. Let $SO(L) = \{ \gamma \in O(L), \det(\gamma) = 1 \}$, which is of index at most 2 in $O(L)$. For an integer $n \in \mathbb{Z}$, $L(n)$ denotes the lattice $(L, n(,))$. An even lattice $L$ is
primitive if $L \not\simeq L'(n)$ for any even lattice $L'$ and $n > 1$. On the other hand, a sublattice $M$ (resp. a vector $l$) of $L$ is said to be primitive if $L/M$ (resp. $L/\mathbb{Z}l$) is free. In the rest of the paper, the distinction between these two notions of primitivity will be clear from the context.

Let $L^\vee = \text{Hom}(L, \mathbb{Z})$ be the dual lattice of $L$, which is canonically embedded in the quadratic space $L \otimes \mathbb{Q}$ and contains $L$. On the finite Abelian group $D_L = L^\vee / L$ a natural quadratic form $q_L : D_L \to \mathbb{Q}/2\mathbb{Z}$ is defined by $q_L(x + L, x + L) = (x, x) + 2\mathbb{Z}$. This finite quadratic form $(D_L, q_L)$, often abbreviated as $D_L$, is called the discriminant form of $L$. A homomorphism $r_L : O(L) \to O(D_L, q_L)$ is defined naturally. For a primitive sublattice $L$ of an even unimodular lattice $M$ with the orthogonal complement $L^\perp$, there exists a canonical isometry (cf. [10])

$$
(2.1) \quad (D_L, q_L) \cong (D_{L^\perp}, -q_{L^\perp}).
$$

The genus $\mathcal{G}(L)$ of an even lattice $L$ is the set of isometry classes of even lattices $M$ satisfying $L \otimes \mathbb{Z}_p \simeq M \otimes \mathbb{Z}_p$ for every prime number $p$ and $\text{sign}(L) = \text{sign}(M)$. By Nikulin’s theorem [10] $L$ and $M$ are in the same genus if and only if $(D_L, q_L) \simeq (D_M, q_M)$ and $\text{sign}(L) = \text{sign}(M)$. We also consider the set $\tilde{\mathcal{G}}(L)$ of orientation-preserving isometry classes of oriented even lattices which (as unoriented lattices) belong to $\mathcal{G}(L)$. The set $\tilde{\mathcal{G}}(L)$ is called the proper genus of $L$. Writing

$$
(2.2) \quad \mathcal{G}_1(L) = \{M \in \mathcal{G}(L) \mid O(M) \neq \text{SO}(M)\}
$$

and $\mathcal{G}_2(L) = \mathcal{G}(L) - \mathcal{G}_1(L)$, we have

$$
(2.3) \quad |\tilde{\mathcal{G}}(L)| = |\mathcal{G}_1(L)| + 2|\mathcal{G}_2(L)|.
$$

The hyperbolic plane is the rank 2 even unimodular lattice

$$
(2.4) \quad U = \mathbb{Z}e + \mathbb{Z}f, \quad (e,e) = (f,f) = 0, \quad (e,f) = 1.
$$

Throughout the paper we fix this basis $\{e,f\}$ for $U$. The orientation-reversing isometry

$$
(2.5) \quad \iota_0 : U \to U, \quad \iota_0(e) = f, \quad \iota_0(f) = e
$$

will be used several times.
3. Weak formulae

3.1. A formula for $\delta(A)$

Let $A$ be an Abelian surface. For a decomposition $(E_1, E_2)$ of $A$ we define an embedding $\varphi: U \hookrightarrow NS_A$ by

\[
\varphi(e) = [E_1], \quad \varphi(f) = [E_2],
\]

where $e, f \in U$ are as defined in (2.4). Since $([E_1], [E_1]) = 0$ and $([E_1], [E_2]) = 1$, $\varphi$ is certainly an embedding of $U$.

**Definition 3.1.** — Let

\[
\Gamma_A := r_{NS}^{-1}\left(\lambda \circ r_T(O_{Hodge}(T_A))\right) \subset O(NS_A),
\]

where $r_{NS}: O(NS_A) \to O(D_{NS_A})$ and $r_T: O(T_A) \to O(D_T)$ are the natural homomorphisms, and $\lambda: O(D_{T_A}) \simeq O(D_{NS_A})$ is the isomorphism induced by the isometry $(D_{T_A}, q_{T_A}) \simeq (D_{NS_A}, -q_{NS_A})$ (see (2.1)).

We have an obvious inclusion $\text{Ker}(r_{NS}) \cdot \{\pm \text{id}\} \subset \Gamma_A$. Let $G$ be the group of Hodge isometries of $H^2(A, \mathbb{Z})$, i.e., isometries of $H^2(A, \mathbb{Z})$ which preserve $H^{2,0}(A)$ in $H^2(A, \mathbb{C})$. By Nikulin’s theorem ([10] Corollary 1.5.2), the group $\Gamma_A$ can be written as

\[
\Gamma_A = \text{Image } (G \to O(NS_A)).
\]

**Proposition 3.2.** — Let $(E_1, E_2)$ and $(F_1, F_2)$ be decompositions of an Abelian surface $A$ and let $\varphi, \psi$ be the corresponding embeddings of $U$. Then $(E_1, E_2)$ and $(F_1, F_2)$ are isomorphic if and only if $\varphi \in \Gamma_A \cdot \psi$.

**Proof.** — If $(E_1, E_2)$ and $(F_1, F_2)$ are strictly isomorphic, there exists an automorphism $f$ of $A$ satisfying $f(E_i) = F_i$. Then $f^*([E_i]) = [E_i]$ and $f^*|_{NS_A} \in \Gamma_A$ so that we have $\varphi \in \Gamma_A \cdot \psi$. Let $\iota_0$ be the isometry of $U$ defined in (2.5). The embedding associated to the decomposition $(E_2, E_1)$ is

\[
\varphi \circ \iota_0 = \left((\varphi \circ \iota_0 \circ \varphi^{-1})|_{\varphi(U)} \oplus \text{id}_{\varphi(U)^-}\right) \circ \varphi \in \Gamma_A \cdot \varphi.
\]

Therefore $\varphi$ and $\psi$ are $\Gamma_A$-equivalent if $(E_1, E_2)$ and $(F_1, F_2)$ are isomorphic.

Conversely, suppose that $\varphi = \gamma \circ \psi$ for some isometry $\gamma \in \Gamma_A$. By (3.3) $\gamma$ can be extended to a Hodge isometry $\Phi: H^2(A, \mathbb{Z}) \to H^2(A, \mathbb{Z})$. When $\det(\Phi) = 1$, Shioda’s Torelli theorem ([12] Theorem 1) assures the existence of an automorphism $f$ of $A$ such that $f^* = \Phi$ or $-\Phi$. Since $\Phi$ preserves the

\[\text{ANNALES DE L'INSTITUT FOURIER}\]

Shouhei MA
cone $C_A^+$, we have $f^* = \Phi$. Then $f^*([F_i]) = [E_i]$ so that $f(E_i) = F_i$. On the other hand, when $\det(\Phi) = -1$, consider the Hodge isometry

$$\Psi := \left( (\varphi \circ \iota_0 \circ \varphi^{-1})|_{\varphi(U)} \oplus \text{id}_{\varphi(U)^\perp} \right) \circ \Phi : H^2(A,\mathbb{Z}) \to H^2(A,\mathbb{Z}).$$

As above, there exists an automorphism $g$ of $A$ such that $g^* = \Psi$. Hence $(E_1,E_2)$ is strictly isomorphic to $(F_2,F_1)$. \hfill \Box

Let

$$\text{Emb}(U,NS_A)$$

be the set of embeddings of $U$ into $NS_A$. By Proposition 3.2 an injective map

(3.4) $\text{Dec}(A) \hookrightarrow \Gamma_A \setminus \text{Emb}(U,NS_A)$

is defined. To prove its surjectivity, we need the following well-known proposition. A non-zero vector $l \in NS_A$ is isotropic if $(l,l) = 0$.

**Lemma 3.3 (cf.[2]).** — Every primitive isotropic vector of $NS_A$ contained in the closure of the cone $C_A^+$ is the class of an elliptic curve in $A$.

Now we have

**Proposition 3.4.** — The map defined in (3.4) is bijective.

**Proof.** — It suffices to prove the surjectivity. Let $\varphi : U \hookrightarrow NS_A$ be an embedding of lattices. Composing with $-\text{id}$ if necessary, we may assume that the vector $\varphi(e)$ is contained in the closure of $C_A^+$. As $(\varphi(e),\varphi(f)) = 1$, the vector $\varphi(f)$ is also contained in the closure of $C_A^+$. By the above Lemma 3.3, there exist elliptic curves $E_1,E_2$ in $A$ such that $[E_1] = \varphi(e)$ and $[E_2] = \varphi(f)$. As $([E_1],[E_2]) = 1$, we have $E_1 \cap E_2 = \{0\}$ so that $(E_1,E_2)$ is a decomposition of $A$. The embedding associated with $(E_1,E_2)$ is $\varphi$. \hfill \Box

**Corollary 3.5.** — An Abelian surface $A$ is decomposable if and only if $NS_A$ admits an embedding of the hyperbolic plane $U$.

**Proposition 3.6.** — Let $L$ be an even lattice satisfying $NS_A \simeq U \oplus L$. Then

$$\left| \Gamma_A \setminus \text{Emb}(U,NS_A) \right| = \sum_{M \in \mathcal{G}(L)} \left| O_{\text{Hodge}}(T_A) \setminus O(D_M)/O(M) \right|.$$

**Proof.** — For each even lattice $M \in \mathcal{G}(L)$ there exists an embedding $\varphi_M : U \hookrightarrow NS_A$ with $\varphi_M(U)^\perp \simeq M$ by Nikulin-Kneser’s uniqueness theorem.
(Corollary 1.13.3 of [10]). We have the decomposition
\[
\Gamma_A \setminus \text{Emb}(U, NS_A) = \bigsqcup_{M \in G(L)} \Gamma_A \setminus \{ \varphi : U \hookrightarrow NS_A, \varphi(U) \perp \simeq M \}
\]
\[
= \bigsqcup_{M \in G(L)} \Gamma_A \setminus (O(NS_A) : \varphi_M)
\]
\[
\simeq \bigsqcup_{M \in G(L)} \Gamma_A \setminus O(NS_A)/O(M).
\]

We apply the homomorphism \( r : O(NS_A) \to O(D_{NS_A}) \), which is surjective by Nikulin’s theorem ([10] Theorem 1.14.2). Since \( \text{Ker}(r) \subset \Gamma_A \), we obtain
\[
\Gamma_A \setminus O(NS_A)/O(M) \simeq r(\Gamma_A) \setminus O(D_{NS_A})/r(O(M))
\]
\[
\simeq r(O_{Hodge}(T_A)) \setminus O(D_M)/r(O(M)).
\]
\[\square\]

By Propositions 3.4 and 3.6 we obtain

**Proposition 3.7.** — Let \( A \) be a decomposable Abelian surface and let \( L \) be an even lattice satisfying \( NS_A \simeq U \oplus L \). Then the decomposition number \( \delta(A) \) is given by
\[
(3.5) \quad \delta(A) = \sum_{M \in G(L)} \left| O_{Hodge}(T_A) \setminus O(D_M)/O(M) \right|.
\]

This formula will be analyzed in more detail in the subsequent sections.

**Remark 3.8.** — The decomposition number is related to the number of principal polarizations. For example see Hayashida [5]. Herbert Lange taught the author that Peter Schuster also studied in his thesis the number of decompositions and principal polarizations by using class numbers of Hermitian forms. See [7] and the references therein for more details.

**3.2. A formula for \( \tilde{\delta}(A) \)**

Let \( A \) be an Abelian surface with \( \rho(A) = 4 \). In this case, the transcendental lattice \( T_A \) is a rank 2 positive-definite even lattice and the Hodge structure of \( T_A \) induces a natural orientation of \( T_A \). An isometry of \( T_A \) preserves the Hodge structure if and only if it preserves the orientation. Thus we have
\[
(3.6) \quad O_{Hodge}(T_A) = SO(T_A).
\]
Since \((D_{T_A}, q_{T_A}) \simeq (D_{NS_A}, -q_{NS_A})\), the lattices \(NS_A\) and \(U \oplus T_A(-1)\) are in the same genus. It follows from Nikulin-Kneser’s uniqueness theorem that

\[
\text{(3.7)} \quad NS_A \simeq U \oplus T_A(-1).
\]

In particular, \(A\) is always decomposable ([13]). Let

\[
\text{(3.8)} \quad ST_A = \Gamma_A \cap SO(NS_A).
\]

For a Hodge isometry \(\Phi\) of \(H^2(A, \mathbb{Z})\) we have \(\det(\Phi) = 1\) if and only if \(\Phi|_{NS_A} \in ST_A\). With this fact in mind, we can prove the following proposition similarly as Propositions 3.2 and 3.4.

**Proposition 3.9.** — Suppose that \(\rho(A) = 4\). For a decomposition \((E_1, E_2)\) of \(A\) we define the embedding \(\varphi : U \hookrightarrow NS_A\) by the equation (3.1). Then this assignment induces the bijection

\[
\widetilde{\text{Dec}}(A) \simeq ST_A \setminus \text{Emb}(U, NS_A).
\]

For each lattice \(T \in G(T_A)\) we can find an embedding \(\varphi_T : U \hookrightarrow NS_A\) with \(\varphi_T(U) \perp T(-1)\). Then, as like the proof of Proposition 3.6, we have

\[
\text{(3.9)} \quad O(NS_A) \cdot \varphi_T \text{ is decomposed as}
\]

\[
O(NS_A) \cdot \varphi_T = SO(NS_A) \cdot \varphi_T \cup SO(NS_A) \cdot (\varphi_T \circ \iota_0),
\]

where \(\iota_0\) is the isometry of \(U\) defined by the equation (2.5).

**Lemma 3.10.** — We have \(\varphi_T \circ \iota_0 \in SO(NS_A) \cdot \varphi_T\) if and only if \(SO(T) \neq O(T)\).

**Proof.** — If \(\varphi_T \circ \iota_0 = \gamma \circ \varphi_T\) for some \(\gamma \in SO(NS_A)\), this \(\gamma\) can be written as

\[
\gamma = (\varphi_T \circ \iota_0 \circ \varphi_T^{-1})|_{\varphi_T(U)} \oplus \gamma'
\]

for some \(\gamma' \in O(T(-1)) = O(T)\). Then \(\det(\gamma') = \det(\gamma) \cdot \det(\iota_0)^{-1} = -1\) so that \(SO(T) \neq O(T)\). The converse is proved similarly. \(\square\)

Therefore we have

\[
| ST_A \setminus (O(NS_A) \cdot \varphi_T) | = \begin{cases} 
| ST_A \setminus SO(NS_A) / SO(T) |, & \text{if } T \in G_1(T_A), \\
2 \cdot | ST_A \setminus SO(NS_A) / SO(T) |, & \text{if } T \in G_2(T_A), 
\end{cases}
\]

where \(G_i(T_A)\) are the subsets of \(G(T_A)\) defined in (2.2). Now an imitation of the proof of Proposition 3.6 yields the following formula involving the proper genus \(\widetilde{G}(T_A)\).
Proposition 3.11. — Let $A$ be an Abelian surface with $\rho(A) = 4$. Then

$$\tilde{\delta}(A) = \sum_{T \in \tilde{G}(T_A)} \left| SO(T_A) \backslash O(D_T_A) / SO(T) \right|.$$ 

We will study this formula more closely in Section 5.

4. The case of Picard number 3

Let $A$ be a decomposable Abelian surface with $\rho(A) = 3$. Then $NS_A \cong U \oplus \langle -2N \rangle$ for some $N \in \mathbb{Z}_{>0}$. This natural number $N$ may be calculated by

$$N = \frac{1}{2} \text{det}(NS_A) = -\frac{1}{2} \text{det}(T_A).$$

We also have the following.

Proposition 4.1. — Let $(E_1, E_2)$ be a decomposition of $A$. Then

$$N = \min \left\{ \text{deg} \phi \mid \phi : E_1 \to E_2 \text{ isogeny} \right\}.$$

In particular, the right hand side of (4.2) is independent of the choice of $(E_1, E_2)$.

Proof. — Let $l \in NS_A$ be a generator of the rank 1 lattice

$$(\mathbb{Z}[E_1] + \mathbb{Z}[E_2])^\perp \cap NS_A \cong \langle -2N \rangle.$$

The class $[E_1] + l + N[E_2] \in NS_A$ is a primitive isotropic vector contained in the closure of $C_A^+$ so that there exists an elliptic curve $E$ in $A$ with $[E] = [E_1] + l + N[E_2]$. Since $([E], [E_2]) = 1$ (resp. $([E], [E_1]) = N$), the degree of the projection $E \to E_1$ (resp. $E \to E_2$) is 1 (resp. $N$). Thus we obtain an isogeny $E_1 \to E \to E_2$ of degree $N$.

Conversely, let $\phi : E_1 \to E_2$ be an arbitrary isogeny. Its graph $\Gamma \subset A$ is an elliptic curve satisfying $([\Gamma], [E_2]) = 1$ and $([\Gamma], [E_1]) = \text{deg}\phi$. We can write $[\Gamma] = [E_1] + a l + (\text{deg}\phi)[E_2]$ for some $a \in \mathbb{Z}$. Then we have

$$\text{deg}\phi = a^2 N \geq N.$$

Note that for $(E_1, E_2)$ as in Proposition 4.1, every isogeny $E_1 \to E_2$ is of degree $a^2 N$ for some $a \in \mathbb{Z}$.

By Proposition 4.1 we have

$$\tilde{\delta}(A) = \begin{cases} 
\delta(A), & \text{if } N = 1, \\
2\delta(A), & \text{if } N > 1.
\end{cases}$$
Proposition 4.2 (cf. [5]). — Let $A$ be a decomposable Abelian surface with $\rho(A) = 3$ and $\det(T_A) = -2N$. Then $\delta(A) = 2^{\tau(N)-1}$. We also have

$$\tilde{\delta}(A) = \begin{cases} 1, & \text{if } N = 1, \\ 2^{\tau(N)}, & \text{if } N > 1. \end{cases}$$

Proof. — The right hand side of the formula (3.5) can be written as

$$\left| O_{Hodge}(T_A) \backslash O(D_{(-2N)}) / O((-2N)) \right|.$$

As $\text{rk}(T_A) = 3$ is odd, it follows from Appendix B of [6] that $O_{Hodge}(T_A) = \{ \pm \text{id} \}$. The isometry group $O((-2N))$ is clearly $\{ \pm \text{id} \}$. Since $D_{(-2N)} = \langle -\frac{1}{2N} \rangle \cong \mathbb{Z}/2NZ$, we have (cf. [6])

$$\left| O(D_{(-2N)}) \right| = \begin{cases} 1, & N = 1, \\ 2^{\tau(N)}, & N > 1. \end{cases} \square$$

Note that $\tilde{\delta}(A)$ can be represented simply as

$$\tilde{\delta}(A) = |O(D_{NS_A})| = |O(D_{T_A})|.$$
Proof. — Since we have $|\Sigma| = |\text{Dec}(A)| = 2^{r(N)-1}$, it suffices to show that $(E_\sigma, F_\sigma)$ and $(E_{\sigma'}, F_{\sigma'})$ are not isomorphic if $\sigma$ and $\sigma'$ are distinct elements of $\Sigma$. By interchanging $\sigma$ and $\sigma'$ if necessary, we may assume that $r_\sigma$ is not divisible by $r_{\sigma'}$. By (4.4) and (4.5), the degrees of the natural projections $E_\sigma \to E$ and $F_\sigma \to E$ are respectively $r_\sigma$ and $b^2_\sigma s_\sigma$. Hence we have an isogeny $E_\sigma \to E_{\sigma'}$ of degree $r_\sigma r_{\sigma'}$ and an isogeny $E_\sigma \to F_{\sigma'}$ of degree $r_\sigma b^2_{\sigma'} s_{\sigma'}$. Since $r_\sigma r_{\sigma'} < N$, we have $E_\sigma \not\cong F_{\sigma'}$. On the other hand, as $b^2_\sigma, s_{\sigma'}$ is coprime to $r_{\sigma'}$, we see that $r_\sigma b^2_{\sigma'} s_{\sigma'}$ is not divisible by $N$. Thus we have $E_\sigma \not\cong E_{\sigma'}$. 

By Proposition 4.3, we see that $\tilde{\text{Dec}}(A)$ is represented completely by the set $\{(E_\sigma, F_\sigma), (F_\sigma, E_\sigma)\}_{\sigma \in \Sigma}$ if $N > 1$.

Remark 4.4. — Let $X_0(N) = \Gamma_0(N) \backslash \mathbb{H}$ be the congruence modular curve of level $N$. When $N > 1$, the decompositions of $A$ are related to each other by the Atkin-Lehner involutions on $X_0(N)$ (see [8]) in the following sense. To a decomposition $(E, F) \in \tilde{\text{Dec}}(A)$ we can associate a point of $X_0(N)$ by considering the pair $(E, \text{Ker}(\phi))$, where $\phi : E \to F$ is an isogeny of the minimal degree $N$. Then, from the definition of $(E_\sigma, F_\sigma)$ above, one can see that the point set in $X_0(N)$ corresponding to $\tilde{\text{Dec}}(A)$ is acted on freely and transitively by the 2-elementary Abelian group of Atkin-Lehner involutions.

Remark 4.5. — Proposition 4.2 can be extended to a counting formula for the set

\[
\text{El}(A) := \text{Aut}(A) \setminus \{ E \subset A \text{ elliptic curve} \}
\]

in the following way. If we denote by $I(\text{NS}_A)$ the set of rank 1 primitive isotropic sublattices of $\text{NS}_A$, then $\text{El}(A)$ is naturally identified with the quotient set $\text{Aut}(A) \setminus I(\text{NS}_A)$. Let $G = \{ f \in \text{Aut}(A), f^*|_{T_A} = \text{id}_{T_A} \}$ be the group of symplectic automorphisms of $A$, which is of index 2 in $\text{Aut}(A)$. We first study the set $G \setminus I(\text{NS}_A)$. The image of $G$ in $O(\text{NS}_A)$ is equal to the group

\[
SO(\text{NS}_A)^+ := \{ \gamma \in SO(\text{NS}_A) \mid r_{\mathbb{Q}}(\gamma) = \text{id} \in O(D_{\text{NS}_A}), \gamma(C_A^+) = C_A^+ \}.
\]

By the theory of Baily-Borel compactification [1], the set $SO(\text{NS}_A)^+ \setminus I(\text{NS}_A)$ is canonically identified with the set of cusps of the orthogonal modular variety $\mathcal{M}$ associated to $SO(\text{NS}_A)^+$. By the tube domain realization, one sees that $\mathcal{M}$ is isomorphic to the modular curve $X_0(N)$. Hence the set $G \setminus I(\text{NS}_A)$ is identified with the set of $\Gamma_0(N)$-cusps, which is well-known. Now the number $|\text{El}(A)|$ is calculated by looking the action of the group $\text{Aut}(A)/G \simeq \mathbb{Z}/2\mathbb{Z}$ on the set of $\Gamma_0(N)$-cusps. This involution is calculated to be $r \mapsto -r$ for $r \in \mathbb{Q}$.
5. The case of Picard number 4

5.1. Counting formulae

Let $A$ be an Abelian surface with $\rho(A) = 4$. As is well-known, the isomorphism class of $A$ is uniquely determined by the proper equivalence class of the transcendental lattice $T_A$ [13]. Therefore it seems natural to express $\delta(A)$ and $\tilde{\delta}(A)$ in terms of the arithmetic of $T_A$. Since $T_A$ is positive-definite of rank 2, the group $SO(T_A)$ is described completely as

$$SO(T_A) \simeq \begin{cases} 
\mathbb{Z}/2\mathbb{Z}, & \text{if } T_A \not\simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}, \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}, \\
\mathbb{Z}/4\mathbb{Z}, & \text{if } T_A \simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}, \\
\mathbb{Z}/6\mathbb{Z}, & \text{if } T_A \simeq \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}.
\end{cases}$$

First we consider the general case: $T_A \not\simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}, \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$. The group $SO(T_A)$ consists of $\{\pm \text{id}\}$ and the genus $G(T_A)$ does not contain the lattices $\begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}, \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$ because they are unique in their genera.

**Proposition 5.1.** — Suppose that $\rho(A) = 4$ and $T_A \not\simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}, \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$. Then

$$\delta(A) = \sum_{T \in G(T_A)} |O(D_T)/O(T)|,$$

$$\tilde{\delta}(A) = \frac{1}{2} \cdot |\tilde{G}(T_A)| \cdot |O(D_{T_A})|.$$

$$\delta_0(A) = \begin{cases} 
\frac{1}{2} \cdot |O(D_{T_A})|, & \text{if } \begin{pmatrix} 2 & 1 \\ 1 & 2c \end{pmatrix} \text{ or } \begin{pmatrix} 2 & 0 \\ 0 & 2c \end{pmatrix} \in G(T_A), \\
0, & \text{otherwise}.
\end{cases}$$

**Proof.** — The first two equalities are deduced immediately from Propositions 3.7 and 3.11. Note that $\text{id} \neq -\text{id}$ in $O(D_{T_A})$ because $|D_{T_A}| > 4$. For the third equality, we have

$$\delta_0(A) = 2\delta(A) - \tilde{\delta}(A) = \sum_{T \in G_1(T_A)} \left\{ 2 \cdot |O(D_T)/O(T)| - |O(D_{T_A})/\{\pm \text{id}\}| \right\} = |G_0(T_A)| \cdot |O(D_{T_A})/\{\pm \text{id}\}|.$$
where $\mathcal{G}_0(T_A) = \{ T \in \mathcal{G}_1(T_A) \mid r_T(O(T)) = \{ \pm \text{id} \} \}$. Let $T \in \mathcal{G}_0(T_A)$. Since $SO(T) \neq O(T)$, it follows from the classification of ambiguous binary forms ([3], Chapter 14.4) that $T$ is isometric to one of the following lattices:

$$
\begin{pmatrix}
2a & 0 \\
0 & 2c
\end{pmatrix}, \quad \begin{pmatrix}
2a & a \\
a & 2c
\end{pmatrix}, \quad a, c \in \mathbb{Z}_{>0}.
$$

If $T = \begin{pmatrix}
2a & 0 \\
0 & 2c
\end{pmatrix}$, $T$ has the orientation-reversing isometry $\gamma = \begin{pmatrix}
1 & 0 \\
0 & -1
\end{pmatrix}$. By the requirement that $r_T(\gamma) \in \{ \pm \text{id} \}$, either $a$ or $c$ must be equal to 1. When $T = \begin{pmatrix}
2a & a \\
a & 2c
\end{pmatrix}$, $T$ admits the orientation-reversing isometry $\sigma = \begin{pmatrix}
-1 & -1 \\
0 & 1
\end{pmatrix}$. Similarly, $a$ or $4c - a$ must be equal to 1. In both cases $T$ is isometric to $\begin{pmatrix}
2 & 0 \\
0 & 2c
\end{pmatrix}$ or $\begin{pmatrix}
2 & 1 \\
1 & 2c
\end{pmatrix}$, $c > 0$. □

Next we study the case $T_A \simeq \begin{pmatrix}2n & 0 \\
0 & 2n\end{pmatrix}$. The group $SO(T_A)$ is the cyclic group $\mathbb{Z}/4\mathbb{Z}$ generated by the rotation $\gamma_1 = \begin{pmatrix}0 & -1 \\
1 & 0\end{pmatrix}$, and the group $O(T_A)$ is the dihedral group of order 8 generated by $\gamma_1$ and the reflection $\gamma_2 = \begin{pmatrix}1 & 0 \\
0 & -1\end{pmatrix}$ with the relations $\gamma_1^4 = \gamma_2^2 = (\gamma_1 \gamma_2)^2 = 1$. The genus $\mathcal{G}(T_A) = \tilde{\mathcal{G}}(T_A)$ consists only of $T_A$. The discriminant form $D_{T_A}$ is the group $(\mathbb{Z}/2n\mathbb{Z})^2$ endowed with the quadratic form $\begin{pmatrix}(2n)^{-1} & 0 \\
0 & (2n)^{-1}\end{pmatrix}$. For brevity, the image of $\gamma_1$ in $O(D_{T_A})$ is again denoted by $\gamma_1$. Straight calculations yield

**Lemma 5.2.** — Let $T_A$ and $\gamma_1$ be as above and assume that $n > 1$. Then the homomorphism $O(T_A) \to O(D_{T_A})$ is injective. For an isometry $\gamma \in O(D_{T_A})$ we have $\gamma^{-1}\gamma_1 \gamma = \det(\gamma)\gamma_1$. As a result, we have

$$
|\langle \gamma_1 \rangle \cdot \gamma \cdot \langle \gamma_1 \rangle| = \begin{cases}
4, & \text{det}(\gamma) = \pm 1, \\
8, & \text{det}(\gamma) \neq \pm 1.
\end{cases}
$$

When $n > 1$, considering the determinant $\det(\gamma) \in \mathbb{Z}/2n\mathbb{Z}$ for $\gamma \in O(D_{T_A})$ induces a surjective homomorphism

(5.1) $O(D_{T_A}) \to (\mathbb{Z}/2\mathbb{Z})^{\tau(n)}$.

Then we have
Proposition 5.3. — Assume that $\rho(A) = 4$ and $T_A \cong \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}$.

Then

$$\delta(A) = \begin{cases} 1, & n = 1, \\ (2^{-4} + 2^{-\tau(n)-3}) \cdot |O(D_{T_A})|, & n > 1, \end{cases}$$

and

$$\tilde{\delta}(A) = \begin{cases} 1, & n = 1, \\ 2\delta(A), & n > 1. \end{cases}$$

Proof. — We may assume that $n > 1$. It follows from Proposition 3.11 and Lemma 5.2 that

$$\tilde{\delta}(A) = |SO(T_A) \setminus O(D_{T_A})/SO(T_A)| = |O(D_{T_A})| \cdot \frac{2^{\tau(n)-1} + 1}{2^{\tau(n)-1} - 1} \cdot \frac{1}{8}$$

The formula for $\delta(A)$ is derived similarly. \qed

Finally we consider the case $T_A \cong \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$. The group $SO(T_A)$ is the cyclic group $\mathbb{Z}/6\mathbb{Z}$ generated by the rotation $\sigma_1 = \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}$, and the group $O(T_A)$ is the dihedral group of order 12 generated by $\sigma_1$ and the reflection $\sigma_2 = \begin{pmatrix} -1 & -1 \\ 0 & 1 \end{pmatrix}$ with the relations $\sigma_1^6 = \sigma_2^2 = (\sigma_1\sigma_2)^2 = 1$. The image of $\sigma_1$ in $O(D_{T_A})$ is again denoted by $\sigma_1$. The genus $G(T_A) = \tilde{G}(T_A)$ consists only of $T_A$.

Lemma 5.4. — If a matrix $\gamma \in GL_2(\mathbb{Z}/n\mathbb{Z})$ satisfies $\det(\gamma)^2 = 1$ and

$$t_\gamma \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix} \gamma \equiv \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix} \mod \begin{pmatrix} 2n\mathbb{Z} & n\mathbb{Z} \\ n\mathbb{Z} & 2n\mathbb{Z} \end{pmatrix},$$

then we have

$$\gamma^{-1} \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix} \gamma = \det(\gamma) \cdot \begin{pmatrix} \frac{\det(\gamma)-1}{2} & -1 \\ 1 & \frac{\det(\gamma)+1}{2} \end{pmatrix}.$$ (5.2)

Proof. — This lemma is proved by direct calculation. \qed

The discriminant group $D_{T_A}$ contains the subgroup $n^{-1}T_A/T_A$ of index 3. We consider the quadratic form on $n^{-1}T_A/T_A$ induced from the discriminant form. The basis of $T_A$ induces that of $n^{-1}T_A/T_A$, with respect to which the quadratic form is written as $\begin{pmatrix} 2n^{-1} & n^{-1} \\ n^{-1} & 2n^{-1} \end{pmatrix}$. As the subgroup $n^{-1}T_A/T_A$ coincides with the subgroup $\{x \in D_{T_A} | nx = 0\}$, it is preserved by the action of $O(D_{T_A})$ so that we have a natural homomorphism

$$\varphi : O(D_{T_A}) \to O(n^{-1}T_A/T_A).$$
With respect to the basis of $n^{-1}T_A/T_A$, the isometry $\varphi(\sigma_1)$ is represented as \( \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix} \).

**Lemma 5.5.** — Let $T_A$, $\sigma_1$, and $\varphi$ be as above and assume that $n > 1$. Then the homomorphism $O(T_A) \to O(D_{T_A})$ is injective. For $\gamma \in O(D_{T_A})$ we have

$$|\langle \sigma_1 \rangle \cdot \gamma \cdot \langle \sigma_1 \rangle| = \begin{cases} 6, & \det(\varphi(\gamma)) = \pm 1, \\ 18, & \det(\varphi(\gamma)) \neq \pm 1. \end{cases}$$

**Proof.** — The first assertion is proved immediately. We prove the second assertion. First consider the case $3 | n$. The quadratic form on $n^{-1}T_A/T_A \subset D_{T_A}$ is degenerated. We can show that the natural homomorphism $\varphi$ is injective and that $\det(\varphi(\gamma))^2 = 1 \in \mathbb{Z}/n\mathbb{Z}$ for $\gamma \in O(D_{T_A})$. By applying Lemma 5.4 to $\varphi(\gamma)$ and $\varphi(\sigma_1)$, we see that

$$|\langle \varphi(\sigma_1) \rangle \cdot \varphi(\gamma) \cdot \langle \varphi(\sigma_1) \rangle| = \begin{cases} 6, & \det(\varphi(\gamma)) = \pm 1, \\ 18, & \det(\varphi(\gamma)) \neq \pm 1. \end{cases}$$

Next consider the case $3 \nmid n$. By the orthogonal decomposition

$$D_{T_A} = (nT_A)/(T_A) \oplus (n^{-1}T_A/T_A) \simeq \mathbb{Z}/3\mathbb{Z} \oplus (\mathbb{Z}/n\mathbb{Z})^2,$$

we have a canonical decomposition

(5.3) \quad $O(D_{T_A}) = O(nT_A/T_A) \oplus O(n^{-1}T_A/T_A)$,

so that $\varphi$ is the natural projection with the kernel $O(nT_A/T_A) \simeq \mathbb{Z}/2\mathbb{Z}$. When $\det(\varphi(\gamma)) = \pm 1$, we see by Lemma 5.4 that $\langle \sigma_1 \rangle$ is normalized by $\gamma$ in $O(D_{T_A})$. When $\det(\varphi(\gamma)) \neq \pm 1$, we have again by Lemma 5.4 that

$$|\langle \sigma_1 \rangle \cdot \gamma \cdot \langle \sigma_1 \rangle| = |\langle \varphi(\sigma_1) \rangle \cdot \varphi(\gamma) \cdot \langle \varphi(\sigma_1) \rangle| = 18.$$

\( \square \)

When $n > 2$ is odd (resp. even), considering the determinant $\det(\varphi(\gamma)) \in \mathbb{Z}/n\mathbb{Z}$ for $\gamma \in O(D_{T_A})$ induces a surjective homomorphism

$O(D_{T_A}) \twoheadrightarrow (\mathbb{Z}/2\mathbb{Z})^{\tau(n)}$ (resp. $O(D_{T_A}) \twoheadrightarrow (\mathbb{Z}/2\mathbb{Z})^{\tau(2^{-1}n)}$).

Similarly as Proposition 5.3, we have

**Proposition 5.6.** — Assume that $\rho(A) = 4$ and $T_A \simeq \binom{2n}{n} \binom{n}{2n}$.

Then

$$\delta(A) = \begin{cases} 1, & n = 1, \\ 3^{-2} \cdot (2^{-2} + 2^{-\tau(2^{-1}n)}) \cdot |O(D_{T_A})|, & n : \text{even}, \\ 3^{-2} \cdot (2^{-2} + 2^{-\tau(n)}) \cdot |O(D_{T_A})|, & n : \text{odd} > 1. \end{cases}$$

and
\[ \tilde{\delta}(A) = \begin{cases} 
1, & n = 1, \\
2\delta(A), & n > 1.
\end{cases} \]

### 5.2. Some conclusions

From Propositions 5.1, 5.3, and 5.6, we have

**Corollary 5.7.** — Let \( A \) and \( B \) be Abelian surfaces with Picard number 4. If \( \text{NS}_A \) is isometric to \( \text{NS}_B \), or equivalently, if \( T_A \) and \( T_B \) are in the same genus, then \( \delta(A) = \delta(B) \) and \( \tilde{\delta}(A) = \tilde{\delta}(B) \).

**Corollary 5.8.** — Let \( A \) be an Abelian surface with \( \rho(A) = 4 \). Then we have \( \delta_0(A) \neq 0 \) if and only if \( T_A \) is primitive and belongs to a principal genus, i.e., \( T_A \) is in the genus of either
\[ \begin{pmatrix} 2 & 0 \\ 0 & 2c \end{pmatrix} \text{ or } \begin{pmatrix} 2 & 1 \\ 1 & 2c \end{pmatrix} \]
for some \( c \in \mathbb{Z}_{>0} \).

Note that Corollary 5.8 can also be proved by Shioda-Mitani’s ideal-theoretic method ([13], Section 4). It must be well-known to experts. For an odd prime number \( p \) and \( a \in (\mathbb{Z}/p\mathbb{Z})^\times \), let \( \chi_p(a) = \left( \frac{a}{p} \right) \) be the Legendre symbol. For an odd number \( n \equiv 1 \mod 8 \), we define
\[ \chi_2(n) = \begin{cases} 
1, & n \equiv 1 \mod 8, \\
-1, & n \equiv 5 \mod 8.
\end{cases} \]

By Proposition 6.8 proved in Section 6 independently, we have the following.

**Corollary 5.9.** — Let \( A \) be an Abelian surface with \( \rho(A) = 4 \) and assume that \( T_A \not\approx \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}, \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix} \). For a natural number \( N > 1 \) let \( A_N \) be the Abelian surface with \( T_{AN} \) properly equivalent to the form \( T_A(N) \).

- (1) The number \( \tilde{\delta}(A_N) \) is divisible by \( \tilde{\delta}(A) \).
- (2) If \( N \) is coprime to \( \det(T_A) \), then
\[ \tilde{\delta}(A_N) = \tilde{\delta}(A) \cdot 2^{\tau(N)} \cdot N \cdot \prod_{p|N} \left( 1 - \frac{\chi_p(-\det(T_A))}{p} \right). \]
- (3) If \( T_A \) is primitive and \( N|\det(T_A)^a \) for some \( a \in \mathbb{Z}_{>0} \), then
\[ \tilde{\delta}(A_N) = \tilde{\delta}(A) \cdot 2^{\tau(N)} \cdot N. \]

We compare our formula with Shioda-Mitani’s formula.
Theorem 5.10 (Shioda-Mitani [13], Theorem 4.7). — Suppose that $\rho(A) = 4$ and that $T_A$ is primitive, i.e., $T_A$ is not isometric to $L(n)$ for any even lattice $L$ and $n > 1$. Let $\mathcal{O}$ be the unique order in an imaginary quadratic field with discriminant $d(\mathcal{O}) = -\det(T_A)$, and $\mathcal{C}(\mathcal{O})$ be the ideal class group of $\mathcal{O}$. Then

\begin{equation}
\tilde{\delta}(A) = |\mathcal{C}(\mathcal{O})|.
\end{equation}

Corollary 5.11. — Let $A$, $\mathcal{O}$ be as in Theorem 5.10. Then

\begin{equation}
|\mathcal{C}(\mathcal{O})| = \frac{1}{2} \cdot |\tilde{G}(T_A)| \cdot |O(D_{T_A})|.
\end{equation}

In particular, the number of genera with discriminant $-\det(T_A)$ is given by $\frac{1}{2}|O(D_{T_A})|$.

Proof. — The first equality (5.7) follows from the comparison of the Shioda-Mitani formula (5.6) and Propositions 5.1, 5.3, 5.6. The group of proper equivalence classes of primitive positive-definite rank 2 even oriented lattices with determinant $\det(T_A)$ is canonically isomorphic to the group $\mathcal{C}(\mathcal{O})$ (see [4] Theorem 7.7). Hence the second assertion follows from the fact that all proper genera in a given class group consist of the same number of classes. □

Of course, Corollary 5.11 can be proved directly without going through decompositions of Abelian surfaces. Shioda-Mitani’s formula is extended as follows.

Corollary 5.12. — Let $A$ be an Abelian surface as in Theorem 5.10 and suppose that $\det(T_A) \neq 3, 4$. For a natural number $N > 1$ let $A_N$ be the Abelian surface as in Corollary 5.9 and $\mathcal{O}_N$ be the order with discriminant $d(\mathcal{O}_N) = -\det(T_A(N))$. Then

\begin{equation}
\tilde{\delta}(A_N) = 2^{\tau(N)} \cdot |\mathcal{C}(\mathcal{O}_N)|.
\end{equation}

Proof. — By the assumption, we have $\tilde{\delta}(A) = |\mathcal{C}(\mathcal{O})|$ for the order $\mathcal{O}$ with $d(\mathcal{O}) = -\det(T_A)$. Then our assertion follows from the comparison of the equations (5.4), (5.5) and [4] Corollary 7.28. □

An ideal-theoretic proof of this corollary is also available.
5.3. Abelian surfaces with decomposition number 1

We shall study Abelian surfaces with $\rho(A) = 4$ and $\delta(A) = 1$. Such Abelian surfaces can be classified as follows:

(i) $T_A$ is primitive, $\tilde{\delta}(A) = 1$.
(ii) $T_A$ is primitive, $\tilde{\delta}(A) = 2$.
(iii) $T_A$ is not primitive, $\tilde{\delta}(A) = 2$.

In the below we see that there are exactly thirteen, twenty-nine, and four Abelian surfaces in the classes (i), (ii), and (iii) respectively.

Example 5.13. — Let $A$ be an Abelian surface such that $\rho(A) = 4$ and $\text{Dec}(A) = \{(E_1, E_2)\}$ for an elliptic curve $E$. Then $E$ is isomorphic to one of the following thirteen elliptic curves:

\[
\{ E\left(\frac{1 + \sqrt{\Delta}}{2}\right) \mid \Delta = -3, -7, -11, -19, -27, -43, -67, -163 \}
\]

\[
\{ E(\sqrt{\Delta}) \mid \Delta = -1, -2, -3, -4, -7 \}
\]

where $E(\tau) = \mathbb{C}/\mathbb{Z} + \mathbb{Z}\tau$.

Proof. — By Corollary 5.8 and Shioda-Mitani formula (5.6), we have $\tilde{\delta}(A) = 1$ if and only if $T_A$ is primitive and the class number $|\mathcal{C}(O)|$ of the corresponding order $O$ is equal to 1. As a result of Heegner-Baker-Stark’s theorem, $T_A$ is one of the following lattices (see [4] Theorem 7.30 (ii)):

\[
\begin{align*}
\begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}, & \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}, & \begin{pmatrix} 2 & 1 \\ 1 & 4 \end{pmatrix}, & \begin{pmatrix} 2 & 0 \\ 0 & 4 \end{pmatrix}, & \begin{pmatrix} 2 & 1 \\ 1 & 6 \end{pmatrix}, & \begin{pmatrix} 2 & 0 \\ 0 & 6 \end{pmatrix}, & \begin{pmatrix} 2 & 0 \\ 0 & 8 \end{pmatrix}, \\
\begin{pmatrix} 2 & 1 \\ 1 & 10 \end{pmatrix}, & \begin{pmatrix} 2 & 1 \\ 1 & 14 \end{pmatrix}, & \begin{pmatrix} 2 & 0 \\ 0 & 14 \end{pmatrix}, & \begin{pmatrix} 2 & 1 \\ 1 & 22 \end{pmatrix}, & \begin{pmatrix} 2 & 1 \\ 1 & 34 \end{pmatrix}, & \begin{pmatrix} 2 & 1 \\ 1 & 82 \end{pmatrix}.
\end{align*}
\]

(5.8)

By Shioda-Mitani theory we can determine the elliptic curve $E$ explicitly from the transcendental lattice $T_A$: see [13], Section 3. □

On the other hand, for those $A$ with primitive $T_A$ and $\delta(A) = 1$, $\tilde{\delta}(A) = 2$ we have the following.

Example 5.14. — There exist natural one-to-one correspondences between the following two sets:

(a) The set of isomorphism classes of Abelian surfaces $A$ with $\rho(A) = 4$ such that $T_A$ is primitive and $\text{Dec}(A) = \{(E_1, E_2)\}$, $E_1 \not\cong E_2$.

(b) The set of imaginary quadratic order with class number 2.
Proof. — For an Abelian surface $A$ in the set (a), we associate the order $O$ with discriminant $d(O) = -\det(T_A)$. By Shioda-Mitani formula we have $|C(O)| = 2$. Then $T_A$ corresponds to the non-trivial element of the class group $C(O)$. □

Imaginary quadratic fields with class number 2 are also classified by [9], [14]. As a result, imaginary quadratic orders with class number 2 are given by the following twenty-nine discriminants:

$$-d(O) = 15, 20, 24, 32, 35, 36, 40, 48, 51, 52, 60, 64, 75, 88, 91, 99,$$

Enumeration of the non-principal forms is a rather straightforward task and is left to the reader.

Example 5.15. — Let $A$ be an Abelian surface with $\rho(A) = 4$ and assume that $T_A$ is not primitive. If $\delta(A) = 1$, then $A$ is isomorphic to one of the following four Abelian surfaces:

$$E(\sqrt{-1}) \times E(2\sqrt{-1}), \quad E(\tau_1) \times E(2\tau_1),$$
$$E(\tau_1) \times E(3\tau_1), \quad E(\tau_2) \times E(2\tau_2),$$

where $\tau_1 = \frac{1+\sqrt{-3}}{2}, \tau_2 = \frac{1+\sqrt{-7}}{2}$, and $E(\tau) = \mathbb{C}/\mathbb{Z} + \mathbb{Z}\tau$.

Proof. — As $T_A$ is not primitive, we see from Corollary 5.8 that $\tilde{\delta}(A) = 2$. First consider the case $T_A \simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}$ with $n > 1$. Since the actions of $SO(T_A)$ preserve the fibres of the determinant homomorphism (5.1), we have $\tau(n) = 1$ so that $SO(T_A)$ is a normal subgroup of $O(D_{T_A})$ by Lemma 5.2. Thus we have $|O(D_{T_A})| = 2$, which implies by Theorem 6.7 that $n = 2$.

In the case of $T_A \simeq \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$ with $n > 1$, we have $n = 2, 3$ by similar argument.

Next consider the case $T_A \not\simeq \begin{pmatrix} 2n & 0 \\ 0 & 2n \end{pmatrix}, \begin{pmatrix} 2n & n \\ n & 2n \end{pmatrix}$. Let $B$ be the Abelian surface such that $T_B$ is primitive and $T_B(n)$ is properly equivalent to $T_A$, $n > 1$. By Corollary 5.9 (1) the number $\tilde{\delta}(B)$ divides $\tilde{\delta}(A) = 2$ so that $\tilde{\delta}(B) = 1$ or $2$. However, the case that $\tilde{\delta}(B) = 2$ is impossible by Corollary 5.9 (2), (3). Thus we have $\tilde{\delta}(B) = 1$ so that $T_B$ is one of the lattices in the list (5.8). It follows from Corollary 5.12 that $n = 2$ and $T_B = \begin{pmatrix} 2 & 1 \\ 1 & 4 \end{pmatrix}$ is the only case. □
6. Order of isometry group of discriminant form

The aim of this section is to calculate the order of the group $O(D_L)$ for a rank 2 even lattice $L$. This section may be read independently of the previous sections. By the orthogonal decomposition $D_L = \bigoplus_p D_p$ where $D_p$ is the $p$-component for the prime number $p$, we have the canonical decomposition

\begin{equation}
O(D_L) = \bigoplus_p O(D_p).
\end{equation}

Thus we first calculate $|O(D_p)|$ for each prime number $p$, and then put them together to $|O(D_L)|$. Throughout this section, a finite quadratic form means a finite Abelian group $D$ endowed with a quadratic form $q : D \to \mathbb{Q}/2\mathbb{Z}$ such that the associated bilinear form $b : D \times D \to \mathbb{Q}/\mathbb{Z}$ is non-degenerate. For a finite quadratic form $(D, q)$ on a $p$-group $D$ with $p \neq 2$, we identify $q$ with the bilinear form $b$.

6.1. Local calculations

By the classification of finite quadratic forms [16], a finite quadratic form on an Abelian $p$-group of length 2 is isometric to one of the following forms:

\begin{align*}
A_{p,k}^{\theta,\theta'} &= \begin{pmatrix} \theta p^{-k} & 0 \\ 0 & \theta' p^{-k} \end{pmatrix} \quad \text{on } (\mathbb{Z}/p^k\mathbb{Z})^2, \quad \theta, \theta' \in \mathbb{Z}_p^\times / (\mathbb{Z}_p^\times)^2, \\
B_{p,l,k}^{\theta,\theta'} &= \begin{pmatrix} \theta p^{-l} & 0 \\ 0 & \theta' p^{-k} \end{pmatrix} \quad \text{on } \mathbb{Z}/p^l\mathbb{Z} \oplus \mathbb{Z}/p^k\mathbb{Z}, \quad l > k, \quad \theta, \theta' \in \mathbb{Z}_p^\times / (\mathbb{Z}_p^\times)^2, \\
V_k &= \begin{pmatrix} 2^{1-k} & 2^{-k} \\ 2^{-k} & 2^{1-k} \end{pmatrix} \quad \text{on } (\mathbb{Z}/2^k\mathbb{Z})^2, \\
U_k &= \begin{pmatrix} 0 & 2^{-k} \\ 2^{-k} & 0 \end{pmatrix} \quad \text{on } (\mathbb{Z}/2^k\mathbb{Z})^2.
\end{align*}

The following proposition is essentially a consequence of successive approximation.

**Proposition 6.1.** — Let $(D, q)$ be a finite quadratic form on a $p$-group with no direct summand of order 2. For the finite quadratic form $(\bar{D}, \bar{q}) = (D/N, p \cdot q)$, $N = \{x \in D, px = 0\}$, the natural homomorphism

\[ \kappa : O(D, q) \to O(\bar{D}, \bar{q}) \]

is surjective.
Then trivial calculation shows that kernel is isomorphic to (6.2)

\[ t \gamma \begin{pmatrix} \theta \\ 0 \\ p^{l-k} \theta' \end{pmatrix} \gamma \equiv \begin{pmatrix} \theta \\ 0 \\ p^{l-k} \theta' \end{pmatrix} \mod \begin{pmatrix} p^l \mathbb{Z} \\ p^l \mathbb{Z} \\ p^l \mathbb{Z} \end{pmatrix}.

Then trivial calculation shows that \( a = d = 0 \) and \( \theta b + \theta' c = 0 \) so that the kernel is isomorphic to \( \mathbb{Z}/p\mathbb{Z} \). For \( p = 2 \), we need to replace (6.2) by the

\[ \mathbb{Z} \] is identified with the homomorphism

\[ \kappa' : O(D_L(p), q_{L(p)}) = O(1/pL^\vee/L, p\cdot q_L) \to O(1/pL^\vee/1/pL, p^2\cdot q_L) \simeq O(D_L, q_L). \]

Consider the natural homomorphisms \( O(L) \to O(D_L) \) and \( O(L(p)) \to O(D_L(p)) \), which are surjective by Corollary 1.9.6 of [10]. Since the diagram

\[ \begin{array}{ccc} O(L(p)) & = & O(L) \\ \downarrow & & \downarrow \\ O(D_L(p)) & \xrightarrow{\kappa'} & O(D_L), \end{array} \]

commutes, we see that \( \kappa' \) is surjective.

Thus natural reduction homomorphisms

\[ O(A_{\theta_0,\theta'}^{p,k}) \to O(A_{\theta_0,\theta'}^{p,k-1}), \quad O(B_{\theta_0,\theta'}^{p,l,k}) \to O(B_{\theta_0,\theta'}^{p,l-1,k-1}), \quad \cdots \]

are defined and are surjective if \( p \neq 2 \) or \( k \geq 2 \).

**Lemma 6.2.** — We have the following isomorphisms.

1. \( \text{Ker}(O(A_{\theta_0,\theta'}^{p,k}) \to O(A_{\theta_0,\theta'}^{p,k-1})) \simeq \mathbb{Z}/p\mathbb{Z} \), where \( k \geq 2 \) if \( p \neq 2 \), and \( k \geq 3 \) if \( p = 2 \).
2. \( \text{Ker}(O(B_{\theta_0,\theta'}^{p,l,k}) \to O(B_{\theta_0,\theta'}^{p,l-1,k-1})) \simeq \mathbb{Z}/p\mathbb{Z} \), where \( k \geq 2 \) if \( p \neq 2 \), and \( k \geq 3 \) if \( p = 2 \).
3. \( \text{Ker}(O(V_k) \to O(V_{k-1})) \simeq \mathbb{Z}/2\mathbb{Z} \) when \( k \geq 2 \).
4. \( \text{Ker}(O(U_k) \to O(U_{k-1})) \simeq \mathbb{Z}/2\mathbb{Z} \) when \( k \geq 2 \).

**Proof.** — We prove only the assertion (2). Other assertions can be proved analogously and are left to the reader. Let \( p \neq 2 \). An isometry \( \gamma \in O(B_{\theta_0,\theta'}^{p,l,k}) \) contained in the kernel of the reduction \( O(B_{\theta_0,\theta'}^{p,l,k}) \to O(B_{\theta_0,\theta'}^{p,l-1,k-1}) \) is represented as

\[ \gamma = \begin{pmatrix} 1 + p^{l-1}a \\ p^{k-1}c \end{pmatrix} \begin{pmatrix} p^{l-1}b \\ 1 + p^{k-1}d \end{pmatrix}, \quad a, b, c, d \in \mathbb{Z}/p\mathbb{Z}. \]

Since \( \gamma \) preserves the quadratic form, we have

\[ \gamma \begin{pmatrix} \theta \\ 0 \\ p^{l-k} \theta' \end{pmatrix} \equiv \begin{pmatrix} \theta \\ 0 \\ p^{l-k} \theta' \end{pmatrix} \mod \begin{pmatrix} p^l \mathbb{Z} \\ p^l \mathbb{Z} \\ p^l \mathbb{Z} \end{pmatrix}. \]

\[ \text{Lemma 6.2.} \]
equation
\[ t \gamma \begin{pmatrix} \theta & 0 \\ 0 & 2^{l-k}\theta' \end{pmatrix} \gamma \equiv \begin{pmatrix} \theta & 0 \\ 0 & 2^{l-k}\theta' \end{pmatrix} \mod \begin{pmatrix} 2^{l+1}Z & 2^l Z \\ 2^l Z & 2^{l+1} Z \end{pmatrix}. \]

\[ \square \]

**Lemma 6.3.** — We have the following isomorphisms.

1. Ker\((O(A^\theta,\theta')) \overset{\cong}{\longrightarrow} O(A^\theta,\theta')\) \(\simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}\).

2. Ker\((O(B^\theta,\theta') \overset{\cong}{\longrightarrow} O(B^\theta,\theta')\) \(\simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}\).

3. If \(p \neq 2\), then Ker\((O(B^\theta,\theta') \overset{\cong}{\longrightarrow} O(B^\theta,\theta')\) is the dihedral group of order \(2p\).

**Proof.** — We prove only the assertion (3). An isometry \(\gamma \in O(B^\theta,\theta')\) contained in the kernel is represented as
\[
\gamma = \begin{pmatrix} 1 + p^{l-1}a & p^{l-1}b \\ c & d \end{pmatrix}, \quad a, b, c, d \in \mathbb{Z}/p\mathbb{Z}.
\]
By the isometry condition we have
\[
d^2 = 1, \quad b = -\theta''dc, \quad a = -2^{-1}\theta''c^2,
\]
where \(\theta'' = \theta^{-1}\theta'\). So there are ambiguities of \(d \in \{\pm id\}\) and \(c \in \mathbb{Z}/p\mathbb{Z}\). It follows that the kernel is generated by
\[
\eta = \begin{pmatrix} 1 - 2^{-1}\theta''p^{l-1} & -\theta''p^{l-1} \\ 1 & 1 \end{pmatrix} \quad \text{and} \quad \sigma = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}
\]
with the relations \(\eta^p = \sigma^2 = (\eta\sigma)^2 = 1\). \(\square\)

**Lemma 6.4.** — Let \(\chi_p(a) = \left( \frac{a}{p} \right)\) be the Legendre symbol for \(p \neq 2\).

1. For \(p \neq 2\), \(O(A^\theta,\theta')\) is the dihedral group of order \(2(p - \chi_p(-\theta'))\).

2. We have
\[
O(A^\theta,\theta') \simeq \begin{cases} \mathbb{Z}/2\mathbb{Z}, & \text{if } \theta\theta' \equiv 1 \mod 4, \\ \{1\}, & \text{if } \theta\theta' \equiv -1 \mod 4. \end{cases}
\]

3. We have
\[
O(B^\theta,\theta') \simeq \begin{cases} \mathbb{Z}/2\mathbb{Z}, & \text{if } l = 2, 3, \\ \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}, & \text{if } l \geq 4. \end{cases}
\]

4. \(O(V_1)\) is the symmetric group \(S_3\).

5. \(O(U_1) \simeq \mathbb{Z}/2\mathbb{Z}\).
Proof. — See Theorem 11.4 of [15] for the assertion (1). The verifications of the assertions (2), (4), (5) are straightforward. We prove (3). Let $\gamma = \begin{pmatrix} a & 2^{l-1}b \\ c & d \end{pmatrix} \in O(B_{2,l,1}^{\theta,\theta'})$, where $a \in \mathbb{Z}/2\mathbb{Z}$ and $b, c, d \in \mathbb{Z}/2\mathbb{Z}$. If we denote $\theta'' := \theta^{-1}\theta'$, the isometry condition for $\gamma$ is the following equations:

\begin{align*}
(6.3) & \quad a^2 + c^2\theta''2^{l-1} \equiv 1 \pmod{2^{l+1}}, \\
(6.4) & \quad b^22^{l-1} + d^2\theta'' \equiv \theta'' \pmod{4}, \\
(6.5) & \quad ab + cd\theta'' \equiv 0 \pmod{2}.
\end{align*}

When $l = 2$, we see that $a = \pm 1$, $b = c = 0$, and $d = 1$. When $l \geq 3$, we have $d = 1$ by (6.4) and $b = c$ by (6.5). There are two possibilities for $c : 0$ or $1$. If $c = 0$, then $a = \pm 1$ satisfy the equation (6.3). If $c = 1$, then the equation (6.3) is written as

\begin{equation}
(6.6) \quad a^2 = 1 - 2^{l-1}\theta'' \pmod{2^{l+1}}.
\end{equation}

When $l = 3$, (6.6) does not have solution. When $l = 4$, (6.6) has solutions $a = \pm (1 + 4\theta'')$. When $l \geq 5$, (6.6) has solutions $a = \pm (1 - 2^{l-2}\theta'')$. □

From Lemmas 6.2, 6.3, and 6.4 we obtain the following results.

**Proposition 6.5.** — Let $p \neq 2$ and $k \geq 1$.

1. We have $|O(A_{p,k}^{\theta,\theta'})| = 2 \cdot p^{k-1} \cdot (p - \chi_p(-\theta'))$.
2. We have $|O(B_{p,l,k}^{\theta,\theta'})| = 4 \cdot p^k$.

**Proposition 6.6.** — We have the following equalities.

1. \[
|O(A_{2,k}^{\theta,\theta'})| = \begin{cases} 
2^k, & -\theta' \equiv 1 \pmod{4}, k \geq 2 \\
2^{k+1}, & -\theta' \equiv -1 \pmod{4}, k \geq 2 \\
1, & -\theta' \equiv 1 \pmod{4}, k = 1 \\
2, & -\theta' \equiv -1 \pmod{4}, k = 1 
\end{cases}
\]

2. \[
|O(B_{2,l,k}^{\theta,\theta'})| = \begin{cases} 
2^{k+1}, & l - k \leq 2, k \geq 2 \\
2^{k+2}, & l - k \geq 3, k \geq 2 \\
2, & l - k \leq 2, k = 1 \\
4, & l - k \geq 3, k = 1 
\end{cases}
\]

3. $|O(V_k)| = 2^k \cdot 3$.
4. $|O(U_k)| = 2^k$. 

Annales de l'Institut Fourier
Let $L$ be an even lattice of rank 2. Denote by $(n,m)$ the invariant factor of $L \subset L^\vee$. That is, we have $n|m$ and there is a basis $\{v_1,v_2\}$ of $L^\vee$ such that $L = \langle nv_1,mv_2 \rangle$. Let

$$n = p_1^{e_1} \cdots p_\alpha^{e_\alpha} \cdot q_1^{f_1} \cdots q_\beta^{f_\beta},$$
$$m = p_1^{e_1} \cdots p_\alpha^{e_\alpha} \cdot q_1^{f_1} \cdots q_\beta^{f_\beta} \cdot r_1^{g_1} \cdots r_{\gamma-1}^{g_{\gamma-1}} \cdot f_i^i > f_i;$$

be the prime decompositions of $n$ and $m$. As groups, the $p$-components $D_p$ of the discriminant group $D_L$ are as follows:

$$D_{p_i} \simeq (\mathbb{Z}/p_i^{e_i} \mathbb{Z})^2, \; D_{q_i} \simeq \mathbb{Z}/q_i^{f_i} \mathbb{Z} \oplus \mathbb{Z}/q_i^{f_i} \mathbb{Z}, \; D_{r_i} \simeq \mathbb{Z}/r_i^{g_i} \mathbb{Z}. $$

For a prime number $p$ dividing $n$, we put

$$\varepsilon_p := \begin{cases} -p^{-2e_i} \cdot \det(L), & p = p_i, \\ 0, & p = q_i. \end{cases}$$

When $D_p \simeq A_{p,e}^{\theta,\theta'}$ as a quadratic form, we have $-\theta \theta' \equiv \varepsilon_p \in \mathbb{Z}_p^\times / (\mathbb{Z}_p^\times)^2$. When $D_2 \simeq U_e$ (resp. $V_e$), we have $\varepsilon_2 \equiv 1$ (resp. 5) mod 8.

For a natural number $n \equiv 1$ mod 4, we define

$$\chi_2(n) = \begin{cases} 1, & n \equiv 1 \text{ mod 8}, \\ -1, & n \equiv 5 \text{ mod 8}. \end{cases}$$

We put $\chi_p(0) := 0$ for an odd prime number $p$. For a natural number $N$ let $\tilde{\tau}(N) := \tau(N)$ if $N > 1$ and $\tilde{\tau}(1) := 0$. Then we have

$$\tilde{\tau}(n) + \tilde{\tau}(n^{-1}m) = \alpha + 2\beta + \gamma.$$

We are now in a position to express the formula for $|O(D_L)|$.

**THEOREM 6.7.** — Let $L,(n,m),\chi_p,$ and $\tilde{\tau}$ be as above.

1. If $D_2$ is either trivial or $U_k$ or $V_k$, or equivalently, if $L \simeq M(2e)$ for an even lattice $M$ with $\det(M)$ odd, then

$$|O(D_L)| = 2^{\tilde{\tau}(n) + \tilde{\tau}(n^{-1}m)} \cdot n \cdot \prod_{p | n} \left(1 - \frac{\chi_p(\varepsilon_p)}{p}\right).$$

2. If $D_2 \simeq A_{2,k}^{\theta,\theta'}$, or equivalently, if $L \simeq M(2e)$ for an odd lattice $M$ with $\det(M)$ odd, then

$$|O(D_L)| = C \cdot 2^{\tilde{\tau}(2^{-1}n) + \tilde{\tau}(n^{-1}m)} \cdot n \cdot \prod_{p | n} \left(1 - \frac{\chi_p(\varepsilon_p)}{p}\right),$$

where $C = 1$ if $\varepsilon_2 \equiv -1$ mod 4, $C = \frac{1}{2}$ if $\varepsilon_2 \equiv 1$ mod 4.

TOME 61 (2011), FASCICULE 2
(3) If \( D_2 \cong B_2^{\theta,\theta'}, \) or equivalently, if \( L \cong M(2^e) \) for an odd lattice \( M \) with \( \det(M) \) even, then
\[
|O(D_L)| = C \cdot 2^{\tau(2-1)n+\tau(n-1)m} \cdot n \cdot \prod_{p|n \atop p \neq 2} \left( 1 - \frac{\chi_p(-\det(L))}{p} \right),
\]
where \( C = 1 \) if \( l - k \geq 3 \), \( C = \frac{1}{2} \) if \( l - k \leq 2 \).

Proof. — This follows immediately from the results of the previous section 6.1. Note that \( D_2 \) is never cyclic. \( \square \)

From Section 6.1 we also deduce the following.

Proposition 6.8. — Let \( L \) be a rank 2 even lattice and \( n > 1 \) be a natural number.

1. The number \( |O(D_{L(n)})| \) is divisible by the number \( |O(D_L)| \).
2. If \( n \) is coprime to \( \det(L) \), we have
\[
|O(D_{L(n)})| = |O(D_L)| \cdot 2^{\tau(n)} \cdot n \cdot \prod_{p|n} \left( 1 - \frac{\chi_p(-\det(L))}{p} \right).
\]
3. If \( L \) is primitive and \( n|\det(L)^a \) for some \( a \in \mathbb{Z}_{>0} \), we have
\[
|O(D_{L(n)})| = |O(D_L)| \cdot 2^{\tau(n)} \cdot n.
\]

Proof. — The assertion (1) follows from Proposition 6.1.

(2) We identify the \( \mathbb{Z} \)-modules underlying \( L \) and \( L(n) \) in a natural way. Since \( n \) is coprime to \( |D_L| \), we have the orthogonal decomposition
\[
D_{L(n)} = (L^\vee/L) \oplus (n^{-1}L/L).
\]

Hence we have
\[
O(D_{L(n)}) = O(D_L) \oplus \bigoplus_{p|n} O(p^{-e}L/L),
\]
where \( n = \prod p^e \) is the prime decomposition of \( n \). If \( p \) is odd, then \( p^{-e}L/L \cong A_{p,e}^{1,\det(L)} \). If \( p = 2 \), we have \( 2^{-e}L/L \cong U_e \) or \( V_e \) according to \(-\det(L) \equiv 1 \) or \( 5 \mod 8 \).

(3) Let \( D_L = \oplus_p D_p \) be the decomposition into \( p \)-components. For \( p \neq 2 \), \( D_p \) is cyclic. On the other hand, \( D_2 \) is either trivial or \( A_2^{\theta,\theta'} \) or \( B_2^{\theta,\theta'} \). Thus our claim follows from Lemmas 6.2 and 6.3. \( \square \)

Acknowledgements. The author wishes to thank Professors Herbert Lange, Matthias Schütt, Ichiro Shimada, Tetsuji Shioda for their valuable comments. The contents of Sections 5.2 and 6.2 were improved considerably.
due to Professor Shioda’s advice. The author is specially grateful to Professor Ken-Ichi Yoshikawa for his encouragement and advices. This work was supported by Grant-in-Aid for JSPS fellows [21-978].
