NICHOLAS M. KATZ
On the intersection matrix of a hypersurface

<http://www.numdam.org/item?id=ASENS_1969_4_2_4_583_0>
ON THE INTERSECTION MATRIX
OF A HYPERSURFACE

BY NICHOLAS M. KATZ.

INTRODUCTION. — Let \((R, m)\) be a complete discrete valuation ring whose residue field has \(q\) elements, and whose fraction field \(K\) has characteristic zero. Let \(X\) be a projective and smooth hypersurface of dimension \(n\) and degree \(d\) over \(R\), in "general position" (see section 1 for a precise definition). Dwork \([3]\) has constructed a finite-dimensional \(K\)-vector space \(W^s\), and an endomorphism \(\alpha\) of \(W^s\), which determines the zeta function \([10]\) of the special fibre \(\bar{X}\) as follows:

\[
Z_{\bar{X}}(t) = \frac{\det \left( 1 - t \frac{\alpha}{q} W^s \right)^{-\chi + 1}}{\prod_{i=0}^n (1 - qt)}.
\]

(0.1)

The verity of the then-conjectural functional equation \([10]\) for \(Z_{\bar{X}}\),

\[
Z_{\bar{X}} \left( \frac{1}{q^\chi t} \right) = \pm q^{n \chi} Z_{\bar{X}}(t)
\]

(0.2)

[here \(\chi\) is minus the degree of \(Z_{\bar{X}}(t)\) as rational function] is equivalent, by (0.1), to the fact that the eigenvalues of \(\frac{\alpha}{q}\) are mapped bijectively to themselves by \(x \mapsto q^n/x\). In order to verify this, Dwork constructed a non-degenerate bilinear pairing

\(W^s \times W^s \to K\)

with respect to which \(q^{n-1} \alpha\) was an isometry (\([4]\), p. 266 and th. 9.2).

The space \(W^s\), together with its pairing, is of a purely algebraic nature, and may be constructed for every hypersurface \(X\), projective, smooth

74.
and in general position over an arbitrary field $K$ of characteristic zero.
There is an isomorphism, $\Theta [7]$, between $W^s$ and $\text{Prim}^s(X/K)$, the subspace of $H_{\text{DR}}^n(X/K)$ consisting of primitive (in the sense of Hodge theory) classes. W. Cassellman conjectured that Dwork's pairing should correspond via $\Theta$ to the cup-product pairing.

Our purpose is to prove that this is essentially the case, i.e., that there exists a non-zero rational number, $c$, depending only on the dimension, $n$, and the degree, $d$, of the hypersurface $X$, such that the following diagram is commutative:

$$
\begin{array}{ccc}
W^s \times W^s & \xrightarrow{c \times \text{(Dwork's pairing)}} & K \\
\downarrow \Theta \times \Theta & & \\
\text{Prim}^s(X/K) \times \text{Prim}^s(X/K) & \xrightarrow{\text{cup-product}} & H_{\text{DR}}^n(X/K)
\end{array}
$$

(The commutativity of this diagram is the only known property of the constant $c$.)

The basic idea is this: the two constructions, $W^s$ and $\text{Prim}^s$, globalize to give locally free sheaves on $T$, the classifying space for nonsingular hypersurfaces of dimension $n$ and degree $d$ in general position. These sheaves are both endowed with integrable connections. The isomorphism $\Theta$ globalizes to an isomorphism of these sheaves, which is compatible with the connections. The desired theorem is then the commutativity of the following diagram of sheaves on $T$:

$$
\begin{array}{ccc}
W^s \times W^s & \xrightarrow{c \times \text{(Dwork's pairing)}} & \mathcal{O}_T \\
\downarrow \Theta \times \Theta & & \\
\text{Prim}^s(X/T) \times \text{Prim}^s(X/T) & \xrightarrow{\text{cup-product}} & H_{\text{DR}}^n(X/T)
\end{array}
$$

Two reductions are now possible. First, it suffices to prove that the above diagram commutes after the base-change which replaces $T$ by the formal neighborhood of a point $s \in T$ (i.e. the completion of the local ring at $s$). Second, both pairings respect the connection (i.e. the "product formula" holds) in the formal neighborhood of the point in $T$ which corresponds to the diagonal hypersurface $\sum_{i=1}^{n+2} X_i^d = 0$; because the connection is integrable, both pairings are then determined by their value at this point.

As explicit formulas for Dwork's pairing at this point are available, the problem is to compute the intersection matrix of the hypersurface $\sum_{i=1}^{n+2} X_i^d = 0$, with respect to a given basis of its De Rham cohomology.

The shape of this matrix is dictated by the presence of a large group of
automorphisms. We succeed in the precise determination only by recourse to a deformation-theoretic method, which consists in differentiating (with respect to the parameters) certain relations in the cohomology ring of the general hypersurface.

1. Some De Rham Cohomology. — Fix positive integers \( n \) and \( d \), and an ordered set of homogeneous coordinates \( X_1, \ldots, X_{n+2} \) for the projective space \( \mathbb{P} = \mathbb{P}^{n+1} \). Let \( S \) be an arbitrary scheme of characteristic zero (i.e. over \( \mathbb{Q} \)). Let \( X \) be a nonsingular hypersurface of dimension \( n \) and degree \( d \), over \( S \), in general position with respect to the coordinates axes. This means \( X \) is defined by the vanishing of a homogeneous form \( F(X_1, \ldots, X_{n+2}) \) of degree \( d \), and that, denoting by \( \mathcal{O}_S[X] \) the sheaf of graded algebras on \( S \) given by \( \mathcal{O}_S[X] = \bigoplus_{k \in \mathbb{Z}} \text{pr}_{k*}(\mathcal{O}_{\mathbb{P}^n}(k)) \),

the Koszul complex defined by the \( \frac{dF}{dX_i} \)

\[
0 \leftarrow \mathcal{O}_S[X] \leftarrow \bigoplus_{1 \leq i \leq n+1} \mathcal{O}_S[X] \leftarrow \bigoplus_{1 \leq i \leq n+2} \mathcal{O}_S[X] \leftarrow \ldots
\]

is exact.

Let us explicitly write the defining equation \( \sum \Lambda_w X^w = 0 \), the sum taken over the \( \binom{n+d+1}{d} \) monomials \( X^w \) of degree \( d \) in \( X_1, \ldots, X_{n+2} \). The coefficients \( \Lambda_w \) are a morphism from \( S \) to the projective space over \( \mathbb{Q} \) of \( \binom{n+d+1}{d} - 1 \) dimensions. This projective space is thus the classifying space for (flat) families of hypersurfaces of degree \( d \) in the "coordinatized" projective space \( \mathbb{P}^{n+1} \) over \( \mathbb{Q} \). It is easily seen (theory of the resultant) that the classifying space for those families which are nonsingular and in general position is a non-empty Zariski open-subset \( T \) of \( \mathbb{P}_S, \star = \binom{n+d+1}{d} - 1 \).

Over \( T \) we dispose of the universal non-singular hypersurface in general position, \( X \to T \), its complement \( \mathbb{P}_T - X \to T \), and the constant projective space \( \mathbb{P}_T \to T \).

Recall that for any smooth morphism \( f : A \to B \), the relative De Rham cohomology sheaves on \( B \), written simply \( \mathcal{H}^r_{\text{dR}}(A/B) \), are, by definition, the \( R^q f_* (\Omega^r_{A/B}) \), and that [6], when \( B \) is (the spectrum of) the complex numbers \( \mathbb{C} \), \( \mathcal{H}^r_{\text{dR}}(A/B) \simeq H^r(A^{an}, \mathcal{C}) \), the second member being the "ordinary" cohomology groups of the associated complex manifold \( A^{an} \). Recall also that the sheaf \( \mathcal{H}^r_{\text{dR}}(A/B) \) is said to commute with base change if, for any morphism \( g : S \to B \), the homomorphism

\[
g^* \mathcal{H}^r_{\text{dR}}(A/B) \to \mathcal{H}^r_{\text{dR}}(A \times_B S/S)
\]

is an isomorphism.
PROPOSITION 1. — The sheaves $H^i_{\text{br}}(X/T)$ and $H^i_{\text{br}}(P - X/T)$ are locally free, and commute with base change.

Proof. — We introduce the coherent complex $\Omega_{P/T}(\log X)$ on $P_T$, whose local sections are the differentials of the form $\omega + \tau \wedge \frac{df}{f}$, where $\omega$ and $\tau$ are local sections of $\Omega^i_{P/T}$ and $f$ is a local equation for $X$ (we write $P/T$ for $P_T/T$). Equivalently, $\Omega_{P/T}(\log X)$ may be described as the tensor product

$$l(X)^{-1} \otimes_{\mathcal{O}_P} (\text{kernel of } \Omega_{P/T} \to \Omega^1_{X/T}),$$

where $l(X)$ is the sheaf of ideals defining $X$ on $P_T$. Because the inclusion $\Omega_{P/T}^i(\log X) \to \Omega^i_{P - X/T}$ is a quasi-isomorphism (i.e., induces an isomorphism of cohomology sheaves), the induced map of sheaves on $T$, $R^i f_*(\Omega_{P/T}(\log X)) \to R^i f_*(\Omega^i_{P - X/T})$ is an isomorphism. Thus from the exact sequence of complexes on $P_T$,

$$0 \to \Omega_{P/T} \to \Omega_{P/T}(\log X) \to \Omega_{X/T}^1 \to 0$$

(1.1)

(1.2)

We will apply the base-changing theorems of ([2], § 7), this being permissible because we are dealing with $T$-flat coherent complexes, $T$-linear differentials, and projective morphisms. Let $s \in T$ be any point, $K(s)$ its residue field, $P_s$ and $X_s$ the corresponding fibres, which are varieties over $K(s)$. We have a corresponding exact sequence of $K(s)$-vector space (by repeating the above construction over $K(s)$)

$$0 \to H^i_{\text{br}}(X_s) \to H^i_{\text{br}}(P_s) \to H^i_{\text{br}}(P_s - X_s) \to H^i_{\text{br}}(X_s) \to$$

and by the Lefschetz theorems [8], $H^i_{\text{br}}(P_s - X_s)$ is zero unless $i = 0$ or $i = n + 1$. Thus ([2], 7.8.3 and 7.8.4) the sheaves $H^i_{\text{br}}(P - X/T)$ are locally free and commute with base change, because these sheaves vanish save for $i = 0$ and $i = n + 1$. Next we remark that each

$$H^i_{\text{br}}(P/T) = H^i_{\text{br}}(P \times \mathbb{A}^T) \cong H^i_{\text{br}}(P/\mathbb{A}) \otimes \mathbb{A}^T$$

is certainly locally free and commutes with base change, and thus the map $H^i_{\text{br}}(P/T) \to H^i_{\text{br}}(P - X/T)$ is zero for $i \geq 1$, this being so at each $K(s)$.

Referring to the exact sequence (1.2), we then see that

$$H^i_{\text{br}}(X/T) \rightarrow H^i_{\text{br}}(P/T) \quad \text{for } i \neq n.$$
Hence, by ([2], 7.8.3), $H^n_{\text{BR}}(X/T)$ is also locally free, and commutes with base change.

Q. E. D.

Recall now that a local section of $H^n_{\text{BR}}(X/T)$ is called primitive [8] if its cup-product with the cohomology class of a hyperplane section is zero.

**Corollary.** — The residue mapping $H^{n+1}_{\text{DR}}(P - X/T) \rightarrow H^n_{\text{DR}}(X/T)$ establishes an isomorphism between $H^{n+1}_{\text{DR}}(P - X/T)$ and $\text{Prim}^n(X/T)$, the sheaf of primitive cohomology classes in $H^n_{\text{DR}}(X/T)$. In particular, $\text{Prim}^n(X/T)$ is locally free and commutes with base change.

**Proof.** — From the exact sequence, we have

$$0 \rightarrow H^{n+1}_{\text{DR}}(P - X/T) \rightarrow H^n_{\text{DR}}(X/T) \rightarrow H^n_{\text{DR}}(P/T) \rightarrow 0.$$ 

Since the restriction mapping $H^{n+2}_{\text{DR}}(P/T) \rightarrow H^{n+2}_{\text{DR}}(X/T)$ is an isomorphism, we may rewrite the above sequence

$$0 \rightarrow H^{n+1}_{\text{DR}}(P - X/T) \rightarrow H^n_{\text{DR}}(X/T) \rightarrow H^n_{\text{DR}}(X/T) \rightarrow 0,$$

where the last map is given by cup-product with the "class of a hyperplane section", whence the corollary, by definition of primitive.

Q. E. D.

We conclude this section by recalling that all the De Rham sheaves are equipped with an integrable connection, that of Gauss-Manin [9], with which all the maps in (1.2) are compatible. The compatibility is most easily seen as follows. For any smooth $g : Y \rightarrow T$, the Gauss-Manin connection is obtained as the differential $d_t$ in the spectral sequence of the filtered object $\Omega^\cdot_{Y/Q}$ with respect to the functor $R^g$, the filtration being defined by

$$F^i(\Omega^\cdot_{Y/Q}) = \text{image}(\Omega^\cdot_{Y/Q} \otimes g^*(\Omega^\cdot_{T/Q}) \rightarrow \Omega^\cdot_{Y/Q}).$$

These considerations apply mutatis mutatis to the complex $\Omega^\cdot_{P \times T/Q}(\log X)$, and provide the $R^f_\cdot(\Omega^\cdot_{P/T}(\log X))$ with an integrable connection. The only point to be checked is that, under the filtration

$$F^i(\Omega^\cdot_{P \times T/Q}(\log X)) = \text{image}(\Omega^\cdot_{P \times T/Q}(\log X) \otimes g^*(\Omega^\cdot_{T/Q}) \rightarrow \Omega^\cdot_{P \times T/Q}(\log X))$$

the associated graded objects are given by

$$\text{gr}^i(\Omega^\cdot_{P \times T/Q}(\log X)) = F^i/F^{i+1} = \Omega^\cdot_{P/T}(\log X) \otimes g^*(\Omega^\cdot_{T/Q}).$$

As the quasi-isomorphism $\Omega^\cdot_{P/T}(\log X) \rightarrow \Omega^\cdot_{P - X/T}$ is the $\text{gr}^0$ of the map $\Omega^\cdot_{P \times T/Q}(\log X) \rightarrow \Omega^\cdot_{P \times T - X/Q}$, the connection on $R^f_\cdot(\Omega^\cdot_{P/T}(\log X))$ corresponds, via the isomorphism $R^f_\cdot(\Omega^\cdot_{P/T}(\log X)) \rightarrow H^\cdot_{\text{DR}}(P - X/T)$, to the
Gauss-Manin connection on $H^s_{dR}(P - X/T)$. Finally, the exact sequence (1.1) is the $gr^a$ of the exact sequence of filtered (as above) complexes

$$0 \to \Omega_{P \times T}^1 \to \Omega_{P \times T}^a (\log X) \to \Omega_{X/T}^{a-1} \to 0,$$

whence the compatibility of the maps in (1.2) with the connections.

2. The constructions of Dwork. — We begin by introducing certain modules over $T$.

$\mathcal{L}$ the free module with base those monomials $X_1^{\omega_1} \ldots X_n^{\omega_n}$, or simply $X^\omega$, with all $\omega_i \geq 0$, and $\sum \omega_i$ divisible by $d$. One defines

$$\omega_0 = \frac{1}{d} \sum_{i=1}^{n+2} \omega_i.$$

$\mathcal{L}^s$, the submodule with base those of the above monomials which in addition have all $\omega_i \geq 1$.

$$W^s = \mathcal{L}^s / \mathcal{L}^s \cap \left( \sum_{i=1}^{n+2} D_i \mathcal{L} \right),$$

where $D_i$ is the $T$-linear mapping

$$D_i : \mathcal{L} \to \mathcal{L}, \quad D_i(X^\omega) = \omega_i X^\omega + X_i \frac{\partial F}{\partial X_i} X^\omega.$$

**Proposition 2.** — The module $W^s$ is locally free, and commutes with base change.

**Proof.** — By the exactness of the Koszul complex for $X$ and its intersections with coordinate hyperplanes, we have

$$\mathcal{L}^s \cap \sum D_i \mathcal{L} = \sum D_i \mathcal{L}^s - 1,$$

where $\mathcal{L}^{s-1}$ is the span of those $X^\omega$ having $\omega_i > 0$, $\forall j \neq i$. Thus $W^s$ as the cokernel of a map between free modules, commutes with base change. By ([3], lemma 3.19), for each point $s \in T$, the corresponding vector space $W^s_{K(s)}$ over the residue field $K(s)$ of $s$ has constant dimension $d^{-1}(d - 1)^{n+2} + (-1)^n(d - 1)$, whence $W^s$ is locally free.

Q. E. D.

We recall that $W^s$ is provided with an integrable connection [9], deduced by passage to quotients from an integrable connection on $\mathcal{L}$. It is defined by having $D \in \text{Der}_q(C_\tau, \mathcal{O}_\tau)$ act through $\sigma_D : \mathcal{L} \to \mathcal{L}$ by

$$\sigma_D(tX^\omega) = D(t)X^\omega + F^b X^\omega,$$

where $t \in C_\tau$, and $F^b$ denotes the result of applying $D$ to the coefficients of $F$.

3. The comparison theorem. — There is a $(T$-linear) map

$$\mathcal{L}^s \to H^{s+1}_{dR}(P - X/T)$$
given by
\[ \mathcal{R} : X^w \rightarrow (-1)^{w-1}(w_0 - 1)! \frac{X^w}{F^{w_0}} \frac{d(X_1/X_{n+2})}{X_1/X_{n+2}} \wedge \ldots \wedge \frac{d(X_{n+1}/X_{n+2})}{X_{n+1}/X_{n+2}}. \]

It is quickly verified that, because all \( w_i \geq 1 \), the above differential form is regular on all of \( \mathbb{P} - X \), and thus defines a section of \( H^{n+1}_{\text{dR}}(\mathbb{P} - X/T) \).

The map \( \Theta : \mathcal{L}^s \rightarrow \text{Prim}^n(X/T) \) is defined to be the composition
\[ \mathcal{L}^s \xrightarrow{\mathcal{R}} H^{n+1}_{\text{dR}}(\mathbb{P} - X/T) \xrightarrow{\text{Prim}^n(X/T)} \text{Prim}^n(X/T). \]

**Theorem 3.** — The maps \( \mathcal{R} \) and \( \Theta \) induce, by passage to quotients, isomorphisms
\[ \mathcal{R} : W^s \xrightarrow{\sim} H^{n+1}_{\text{dR}}(\mathbb{P} - X/T), \]
\[ \Theta : W^s \xrightarrow{\sim} \text{Prim}^n(X/T), \]
which are compatible with the connections.

**Proof.** — We first show that \( \mathcal{L}^s \cap \sum D_i \mathcal{L} \) lies in the kernel of \( \Theta : \mathcal{L}^s \rightarrow \text{Prim}^n(X/T) \). As \( \text{Prim}^n(X/T) \) is locally free and commutes with base change, it suffices to show that for every \( s \in T \), the corresponding map \( \Theta_s : \mathcal{L}^s \rightarrow \text{Prim}^n(X_s) \) of \( K(s) \) vector spaces annihilates \( \mathcal{L}^s \cap \sum D_i \mathcal{L} \).

By ([7], th. 1.17), the composition
\[ \mathcal{L}^s \xrightarrow{\Theta_s} \text{Prim}^n(X_s) \xrightarrow{\text{restriction}} H^n_{\text{dR}}(X_s^{\Theta}) \]
(here \( X_s^{\Theta} \) is the open subset of \( X_s \) where all coordinates \( X_i \) are invertible) annihilates \( \mathcal{L}^s \cap \sum D_i \mathcal{L} \). By ([7], cor. 1.11), temporarily writing \( X_s^{(1)} \) for the open subset of \( X_s \) where the first coordinate \( X_1 \) is invertible, the restriction map
\[ H^n(X_s^{(1)}) \rightarrow H^n(X_s^{\Theta}) \]
is injective. And
\[ H^n(X_s) = \text{Prim}^n(X_s) \oplus \text{Kernel of } (H^n(X_s) \rightarrow H^n(X_s^{(1)})), \]
whence \( \text{Prim}^n(X_s) \rightarrow H^n_{\text{dR}}(X_s^{\Theta}) \) is injective.

To show that \( \Theta : W^s \rightarrow \text{Prim}^n(X/T) \) is an isomorphism, it suffices, since both \( W^s \) and \( \text{Prim}^n(X/T) \) are locally free, to show it over the residue field of each \( s \in T \). This is so in virtue of ([7], th. 1.17). That \( \mathcal{R} \) (and hence \( \Theta \)) transforms \( \sigma \) into the Gauss-Manin connection is seen directly
\[ \mathcal{R}(\sigma_0(X^w)) = \mathcal{R}(F^wX^w) = (-1)^{w-1}(w_0 - 1)! \frac{F^wX^w}{F^{w_0}} \frac{d(X_1/X_{n+2})}{X_1/X_{n+2}} \wedge \ldots \wedge \frac{d(X_{n+1}/X_{n+2})}{X_{n+1}/X_{n+2}} \]
while
\[ D(\mathcal{R}(X^w)) = D\left\{ (-1)^{w-1}(w_0 - 1)! \frac{X^w}{F^{w_0}} \frac{d(X_1/X_{n+2})}{X_1/X_{n+2}} \wedge \ldots \wedge \frac{d(X_{n+1}/X_{n+2})}{X_{n+1}/X_{n+2}} \right\} \]
and, as $D$ annihilates all $X_i/X_{i+1}$, $i = 1, \ldots, n$, this is
\[ (-1)^w \frac{F^w X^w}{F^{w+1}} \left( \frac{d(X_1/X_{n+1})}{X_1/X_{n+1}} \wedge \ldots \wedge \frac{d(X_{n+1}/X_{n+2})}{X_{n+1}/X_{n+2}} \right). \]
Q. E. D.

4. The Intersection Matrix. — Any $T$-bilinear pairing
\[ \text{Prim}^n(X/T) \times \text{Prim}^n(X/T) \to H^0(T)(X/T) \cong \mathcal{O}_T \]
may be thought of as a global section of the locally free sheaf
\[ \text{Hom}_{\mathcal{O}_T}(\text{Prim}^n(X/T) \otimes_{\mathcal{O}_T} \text{Prim}^n(X/T), \mathcal{O}_T). \]
Because $T$ is (reduced and) irreducible, for any non-void open subsets $U \subset V$ of $T$, and any locally free sheaf $F$ on $T$, the restriction mapping on sections $\Gamma(V, F) \to \Gamma(U, F)$ is injective. Fixing a point $s \in T$, we have $\Gamma(V, F) \subset \text{lim} \Gamma(U, F) = F_s$, the stalk at $s$. Since the local ring $\mathcal{O}_{T,s}$ at $s$ is noetherian, it follows by Krull's Intersection Theorem that $\mathcal{O}_{T,s}$ is a subring of its completion $\hat{\mathcal{O}}_{T,s}$; $F$, being free over $\mathcal{O}_{T,s}$, we have $F \subset \hat{F} = F \otimes_{\mathcal{O}_{T,s}} \hat{\mathcal{O}}_{T,s}$. Denote by $\hat{X}$, the fibre product $X \times_T \hat{\mathcal{O}}_{T,s}$, which may be thought of as a tubular neighborhood of the special fibre $X_s = X \times_T K(s)$.

**Proposition 4.** — Let $s \in T$ be a closed point which is $Q$-rational. Then the $\hat{\mathcal{O}}_{T,s}$-module $\text{Prim}^n(\hat{X}/\hat{\mathcal{O}}_{T,s})$ admits a basis of horizontal (for the Gauss-Manin connection) elements.

**Proof.** — The hypersurface $\hat{X}$, is given by an equation
\[ X^d + \sum_{w} (a_w + \Lambda_w) X^w = 0, \]
where the sum is over all monomials $X^w$ of degree $d$ other than $X^d$, and the $\Lambda_w$ are independent variables, with $\hat{\mathcal{O}}_{T,s} = Q[[\Lambda_w]]$. The hypersurface $X$, is given by $X^d + \sum a_w X^w = 0$.

[We have used the fact that all the monomials $X^d$ necessarily occur in the equation of an $X$ in general position.] Let $\{ \tau_i \}$ be a basis of $\text{Prim}^n(\hat{X}/\hat{\mathcal{O}}_{T,s})$. Each $\frac{\partial}{\partial \Lambda_w}$ acts; say $\frac{\partial \tau_i}{\partial \Lambda_w} = \sum_f B_{i,f}(w) \eta_f$. If it possible to find a basis of horizontal sections $\tau_i$, which agree with the $\tau_i$ over the residue field of $s$, they will necessarily be linear combinations of the $\tau_i$,
\[ \tau_i = \sum_f u_{ij} \eta_j, \quad u_{ij} \in Q[[\Lambda_w]], \]
where the matrix \( U = (u_{ij}) \) satisfies the equation
\[
\frac{\partial U}{\partial \Lambda_w} = - UB(w) \quad \text{for each } \Lambda_w; \quad \text{here } B(w) = (B_i, f(w)), \\
U(o) = I.
\]

That this system has a unique solution results from the formal version of the Frobenius theorem on "complete integrability", applicable precisely because the Gauss-Manin connection is integrable ([1], p. 304).

Q. E. D.

**Remark.** — The inverse \( P \) of the matrix \( U \), by means of which the \( \eta_i \); may be expressed in terms of the horizontal basis, is nothing other than the classical period matrix. Let us explain why this is so. Consider a proper and smooth (holomorphic) map \( f: Y \to \Delta \), where \( \Delta \) is the unit disc \( |t| < 1 \). Replacing \( \Delta \) if necessary by a smaller disc around \( o \), we may suppose that \( f: Y \to \Delta \) is a differentiably trivial fibre bundle. Choose a \( \mathbb{C}^* \) trivialization \( \gamma: Y \to Y_0 \times \Delta \) [here \( Y_0 = f^{-1}(o) \)]. Let \( \{ \eta_i(t) \} \) be a basis of \( H^1_{pr}(Y/\Delta) \). The horizontal basis \( \{ \gamma_i(t) \} \) is obtained as follows; for each \( t \in \Delta \), \( \gamma \) induces \( \gamma_i: Y \to Y_0 \), and we take \( \tau_i(t) = \gamma_i^*(\eta_i(o)) \). Let \( \tau_i(o) \) be the basis of \( H^1(Y_0, \mathbb{C}) \) dual to the \( \eta_i(o) \), and define a basis \( \tau_i(t) \) of \( H^1(Y_0, \mathbb{C}) \) by \( \tau_i(t) = \gamma_i^*(\tau_i(o)) \). Clearly we have
\[
\int_{\gamma_i(t)} \tau_i(t) = \int_{\gamma_i(t)} \gamma_i^*(\eta_i(o)) = \int_{\gamma_i([\gamma_i(t)])} \eta_i(o) = \int_{\gamma_i(o)} \eta_i(o) = \delta_i, j.
\]
Hence \( \eta_i(t) = \sum_j (\int_{\gamma_i(t)} \tau_i(t)) \tau_j(t) \) in \( H^1(Y_0, \mathbb{C}) \), as both sides have the same integral over each cycle \( \gamma_j(t) \). Thus the "variable" sections \( \eta_i(t) \) are expressed in terms of the horizontal sections \( \tau_i(t) \) by means of the matrix of periods \( \int_{\gamma_i(t)} \eta_i(t) \).

**Proposition 5.** — Assumptions as in Proposition 4, under the cup-product pairing
\[
\text{Prim}^n(\hat{X}_x/\hat{\mathcal{O}}_{Y,s}) \times \text{Prim}^n(\hat{X}_x/\hat{\mathcal{O}}_{Y,s}) \to H^1_{HH}(\hat{X}_x/\hat{\mathcal{O}}_{Y,s}) \sim \hat{\mathcal{O}}_{Y,s}
\]
the cup-product of two horizontal classes, \( \tau_i \wedge \tau_j \) is a rational number.

**Proof.** — Each \( \frac{\partial}{\partial \Lambda_w} \) acts, through the Gauss-Manin connection, as a **derivation** of the cohomology algebra [9], and the connection on \( H^1_{HH}(\hat{X}_x/\hat{\mathcal{O}}_{Y,s}) \sim \hat{\mathcal{O}}_{Y,s} \) is just ordinary differentiation. Thus \( \tau_i \wedge \tau_j \) is an element of \( \mathbb{Q}[[\Lambda_w]] \), and
\[
\frac{\partial}{\partial \Lambda_w}(\tau_i) = \frac{\partial}{\partial \Lambda_w}(\tau_i \wedge \tau_j) \tau_i \wedge \tau_j + \tau_i \wedge \frac{\partial \tau_i}{\partial \Lambda_w} = 0 + 0.
\]
Q. E. D.
Let \( \{ \tau_i \} \) be a basis of \( \text{Prim}^n(\mathbb{X}_s/\hat{\mathcal{O}}_{T,s}) \), and \( \{ \tau_i \} \) the basis of horizontal sections such that for each \( i \), \( \tau_i \cdot \eta_i \) induces \( \sigma \) in \( \text{Prim}^n(\mathbb{X}_s/K(s)) \). Let \( P = (P_{ij}) \) be the period matrix
\[
\eta_i = \sum P_{ij} \tau_j.
\]

The intersection matrix \( M = (M_{ij}) \), \( M_{ij} = \eta_i \cap \eta_j, \) is given by
\[(4.1) \quad M = PJP^t,
\]
where \( J \) is the value of \( M \) at \( s \), i.e. the matrix of rational numbers \( \tau_{ij} = \eta_i(s) \cap \eta_j(s) \) \( (\eta_i(s) \in \text{Prim}^n(\mathbb{X}_s/\mathbb{Q}) \) being the class induced by \( \eta_i). \)

5. The Pairing of Dwork. — The pairing was constructed in a bootstrap way (historically). Near the point \( s \in T \) which corresponding to the diagonal hypersurface of equation \( \sum X_i = 0 \), a basis of \( W^s \) is given by the monomials
\[
X^w \text{ satisfying } \begin{cases} \sum_{i=1}^{n+2} w_i X_i = 0, \\ w_i \in \mathbb{Z}, \\ 1 \leq w_i \leq d - i \text{ for } i = 1, \ldots, n + 2. \end{cases}
\]
Such an exponent system \( w = (w_1, \ldots, w_{n+2}) \) is called admissible. For each admissible exponent system \( w = (w_1, \ldots, w_{n+2}) \), define the dual system by \( \bar{w} = (d - w_1, \ldots, d - w_{n+2}) \). Clearly \( w \mapsto \bar{w} \) is an involution of admissible exponent systems.

The pairing ([4], p. 248-251) on the \( \mathbb{Q} \)-vector space \( W^s(s) \) is defined by
\[
(X^u, X^v)_s = \begin{cases} (-1)^{w_1} & \text{if } u = \bar{v}, \\ 0 & \text{if not}. \end{cases}
\]
It is extended "locally" ([4], p. 266-267), i.e. to \( W^s \otimes \hat{\mathcal{O}}_{T,s} \), by requiring \( \hat{\mathcal{O}}_{T,s} \), bilinearity and that, for any two horizontal elements \( \tau_1 \) and \( \tau_2 \), the product \( (\tau_1, \tau_2) \) is the rational number defined above by \( (\tau_1(s), \tau_2(s)) \). This does define a pairing, since, just as in Proposition 4, \( W^s \otimes \hat{\mathcal{O}}_{T,s} \) admits an \( \hat{\mathcal{O}}_{T,s} \) base of horizontal elements. Let \( \tau_w \) be the horizontal section whose specialization at \( s \) is \( X^w \).

By transport of structure by \( \Theta \), the expression of the elements \( X^w \) in terms of the horizontal elements \( \tau_w \) is given by a matrix \( P = (P_{w,u}) \):
\[
X^w = \sum_u P_{w,u} \tau_u \text{ in } W^s \otimes \hat{\mathcal{O}}_{T,s}.
\]
P is the *period* matrix, expressing
\[ \Theta(X^u) = \sum_u p_{u, v} \Theta(\tau_u) \]
in \( \text{Prim}^n(X_0/\hat{O}_{T, s}) \).

Thus Dwork's local intersection matrix \( M' = M'_{u, v} = (X^u, X^v) \) is given by
\[ (5.1) \quad M' = \mathcal{P}J \mathcal{P}', \]
where
\[ J'_{u, v} = \begin{cases} (-1)^{\nu_u}, & \text{if } u = v, \\ 0, & \text{if } \nu_u \neq \nu_v. \end{cases} \]

Dwork then constructs an \( \mathcal{O}_T \)-bilinear pairing
\[ W^s \times W^s \to \mathcal{O}_T \]
which extends the one described above ([4], p. 267-282, esp. th. 6.2). As explained in section 4, such an extension is necessarily unique. Since we will make use only of local properties, we will not describe the extension.

6. The Intersection Matrix of a Diagonal Hypersurface. — This section is devoted to proving

**Theorem 6.** — Dwork's pairing corresponds to (a constant multiple of) the cup-product, i.e. the following diagram is commutative for some non-zero constant \( c \in \mathbb{Q} \), which depends only on the dimension, \( n \), and the degree, \( d \),
\[ W^s \times W^s \xrightarrow{\times (\text{Dwork's pairing})} \mathcal{O}_T \]
\[ \xrightarrow{\Theta \times \Theta} \]
\[ \text{Prim}^n(X/T) \times \text{Prim}^n(X/T) \xrightarrow{\text{cup-product}} H^n_{DR}(X/T) \]

**Proof.** — As explained in section 4, it suffices to show this is so after the base extension \( \text{Spec}(\hat{O}_{T, s}) \to T \), i.e., that it is so in the formal neighborhood of the point \( s \in T \) corresponding to the hypersurface \( X(n, d) \) of equation \( \sum_{i=1}^{n+2} X_i^d = 0 \). Comparing (4.1) and (5.1), the pairings are given by \( \mathcal{P}J \mathcal{P}' \) and \( \mathcal{P}'J' \mathcal{P} \) respectively. Thus we must show that there is a constant \( c \) such that \( J' = cJ \), i.e., that under the cup-product pairing
\[ \text{Prim}^n(X(n, d)) \times \text{Prim}^n(X(n, d)) \to \mathbb{Q} \]
we have
\[ \Theta(X^u) \wedge \Theta(X^v) = c(-1)^{\nu_u} \delta_{u, v}, \]
for each pair \( u, v \) of admissible exponent systems.
Lemma 7. — Let $u$ and $v$ be admissible, and $u \neq \overline{v}$. Then

$$\Theta(X^u) \wedge \Theta(X^v) = 0.$$ 

Proof. — Extending the ground field from $\mathbb{Q}$ to $K = \mathbb{Q}(\exp(2\pi i/d))$, we introduce the action of the group $G = (\mathbb{Z}_d)^{n+2}$, which acts on $P^{n+1}$, $X(n, d)$, $P^{n+1} - X(n, d)$, etc., via

$$g(X_1, \ldots, X_{n+1}) = (\zeta_1 X_1, \ldots, \zeta_{n+1} X_{n+1}).$$

Here $g = (\zeta_1, \ldots, \zeta_{n+1}) \in (\mathbb{Z}_d)^{n+2}$, and $(X_1, \ldots, X_{n+1})$ are the homogeneous coordinates.

To each admissible exponent system $w$ we associate the character $\chi_w$ of $G$ defined by

$$\chi_w(g) = \zeta_1^{w_1} \cdots \zeta_{n+1}^{w_{n+1}} \quad \text{for} \quad g = (\zeta_1, \ldots, \zeta_{n+1}).$$

For each admissible system $w$, we claim

$$g(\Theta(X^w)) = \zeta_w(g) \Theta(X^w).$$

This is so because:

1. $\Theta(X^w) = \text{res} (\partial (X^w));$

2. $\partial (X^w) = (-1)^{w_{d-1}} (w_{d-1})! \frac{X^w}{(\sum X^2)^{w_1}} \frac{d(X_1/X_{n+1})}{(X_1/X_{n+1})} \cdots \frac{d(X_{n+1}/X_{n+2})}{(X_{n+1}/X_{n+2})},$

a differential which obviously transforms under $G$ by $\chi_w$, and $3^0$ the residue map $H^1(P^{n+1} - X(n, d)) \otimes K \to H^1(X(n, d)) \otimes K$ commutes with the action of $G$.

The product $\Theta(X^u) \wedge \Theta(X^v)$ is thus an element of $H^{2n}_\text{dR}(X(n, d))$ which transforms under $G$ by $\chi_u \chi_v$. But $G$ acts trivially on $H^{2n}_\text{dR}(X(n, d)) \otimes K$, and thus either

$$\Theta(X^u) \wedge \Theta(X^v) = 0, \quad \text{or} \quad \chi_u = \chi_v^{-1},$$

in which case $u = \overline{v}$.

Q. E. D.

Thus it remains to show that for each admissible exponent system $u$,

$$\Theta(X^u) \wedge \Theta(X^\overline{u}) = c(-1)^{w_u},$$

where $c$ is independent of $u$. We first do this in some special cases:

I. $d = 1$, any $n$; then $\text{Prim}^n(X(n, 1)) = 0$;

II. $d = 2$, any $n$; $\text{Prim}^n(X(n, 2))$ is zero if $n$ is odd, and is one-dimensional, spanned by $\Theta\left(\prod_{i=1}^{n+2} X_i\right)$, is $n$ if even;

III. $d = 3$, $n = 2$. The six admissible exponent systems

$$w = (w_1, w_2, w_3, w_4)$$
are
\[(1, 1, 2, 2), (2, 2, 1, 1), (1, 3, 1, 2), (2, 1, 2, 1), (1, 2, 2, 1), (2, 1, 1, 3);\]
with dual pairs written together.

Let the symmetric group \( S_4 \) act on \( \mathbb{P}^3, X(2, 3), \) ... by permuting the homogeneous coordinates:
\[\sigma(X_1, X_2, X_3, X_4) = (X_{\sigma(1)}, X_{\sigma(2)}, X_{\sigma(3)}, X_{\sigma(4)}).\]

By functoriality, the mapping residue : \( H^3(\mathbb{P}^3 - X(2, 3)) \to \text{Prim}^3(X(2, 3)) \)
commutes with the action of \( \sigma \), and by direct computation
\[\text{res} : W^s \to H^3(\mathbb{P}^3 - X(2, 3))\]
commutes "up to the signature", i.e.
\[\text{res}(\sigma(X^w)) = \text{sgn}(\sigma) \text{res}(X^w).\]

Thus \( \Theta(\sigma(X^w)) = \text{sgn}(\sigma) \Theta(X^w) \), and, as the involution \( \omega \to \bar{\omega} \) commutes
with the action of \( S_4 \), we have
\[\Theta(\sigma(X^w)) \wedge \Theta(\sigma(X^{\bar{w}})) = \Theta(X^w) \wedge \Theta(X^{\bar{w}}).\]

As \( S_4 \) acts transitively on the six admissible systems for \( X(2, 3) \), this completes case III.

The proof of Theorem 6 will be completed by the next proposition, in which we return to the universal \( X \to T \).

**Proposition 8.** — Suppose \( n \geq 1, d \geq 3 \), and either \( n \neq 2 \) or \( d \neq 3 \).
For each admissible exponent system \( \omega \), the element \( X^w \in \mathcal{L}^s \) determines a global section, \( \Theta(X^w) \), of \( \text{Prim}^n(X/T) \). For any two admissible systems \( u \) and \( v \), one has
\[\Theta(X^u) \wedge \Theta(X^v) = (-1)^{w_{uv}} \Theta(X^u) \wedge \Theta(X^{\bar{v}}) \text{ in } \mathcal{O}_T.\]

**Proof.** — It suffices to demonstrate the equality over the local ring of the generic point of \( T \), i.e. to consider the hypersurface \( X \) of equation
\[X^d + \sum_{w} A_w X^w \text{ (where the sum is over all monomials } X^w \text{ of degree } d\]
other than \( X_i^d \), and the \( A_w \) are independent variables) over the field \( K = \mathbb{Q}(A_w) \).

The spectral sequence associated to the filtration of \( \Omega_{X/K} \) by the subcomplexes
\[E^1(\Omega_{X/K}) = 0 \to 0 \to \cdots \to 0 \to \Omega_{X/K}^1 \to \Omega_{X/K}^{2} \to \cdots,\]
has \( E^{p,q}_1 = H^q(X, \Omega_{X/K}^p) = H^p_{\text{dR}}(X/K) \).

By Hodge theory, this spectral sequence degenerates at \( E_1 \) for any projective nonsingular \( X \) over a field \( K \) of characteristic zero. This means
that the associated graded objects \( \text{gr}^p H^p_{\text{DR}}(X/K) \) are given by \( H^p(X, \Omega^p_{X/K}) \).

In particular, because \( n = \dim X/K \), \( \text{gr}^p H^n_{\text{DR}}(X/K) \) vanishes for \( p \neq n \). Thus \( F^p H^n_{\text{DR}}(X/K) = 0 \) for \( p > n \).

Because the filtration \( F^i \) of \( \Omega^i_{X/K} \) is "multiplicative",

\[
F^i \Omega^i_{X/K} \cap F^j \Omega^i_{X/K} \subseteq F^{i+j} \Omega^i_{X/K},
\]

it follows that

\[
F^i H^n_{\text{DR}}(X/K) \cap F^j H^n_{\text{DR}}(X/K) \subseteq F^{i+j} H^n_{\text{DR}}(X/K).
\]

Thus if \( \xi \in F^i H^n_{\text{DR}}(X/K) \), \( \eta_i \in F^j H^n_{\text{DR}}(X/K) \) and \( i + j > n \), then \( \xi \cap \eta_i = 0 \).

Now consider any monomial \( X^w \in \mathbb{Z}^g \). We have \( \Theta(X^w) = \text{residue} (\mathcal{R}(X^w)) \).

The class \( \mathcal{R}(X^w) \) is represented by a form holomorphic on \( \mathbb{P}^{n+1} - X \), which has a pole of order (at most) \( \omega_o \) along \( X \). It follows ([5], § 8) that its residue lies in \( F^{n+1-\omega_o} H_{\text{DR}}^n(X/K) \).

Thus if \( u \) and \( \nu \) are admissible exponent systems with \( u_o + \nu_o \leq n + 1 \), one has \( \Theta(X^u) \cap \Theta(X^\nu) = 0 \).

Let us say that two admissible exponent systems \( u \) and \( \nu \) are connected if either \( u \succeq \nu \) (meaning \( u_i \geq \nu_i \) for all \( i \)) or \( \nu \succeq u \).

As a first step towards Proposition 8, we prove

**Lemma 9.** — When \( u \) and \( \nu \) are admissible exponent systems which are connected, the conclusion of Proposition 8 is valid.

**Proof.** — Say \( u \succeq \nu \); since we may clearly interpolate a sequence of admissible systems

\[
u = u^{(0)} \succeq u^{(1)} \succeq \ldots \succeq u^{(e)} = \nu
\]

with \( u^{(i)}_o = 1 + u^{(i+1)}_o \), it is enough to check the case \( u_o = 1 + \nu_o \).

Let us write \( u = \nu + \omega \); then \( \tilde{\nu} = \tilde{u} + \nu \) (because \( \nu + \tilde{\nu} = u + \tilde{u} \)).

Recall the connection \( \sigma \) on \( W^s \), induced by \( \sigma_o = D + F^o \). In particular, taking the derivation \( \frac{\partial}{\partial \Lambda_w} \), defined by \( \frac{\partial}{\partial \Lambda_w} (A_x) = \delta_{w,x} \), and writing \( \sigma_w \) for \( \sigma_{A_w} \), we have

\[
\sigma_w = \frac{\partial}{\partial \Lambda_w} + X^w
\]

whence

\[
\begin{cases}
\sigma_w(X^u) = X^u, \\
\sigma_w(X^{\nu}) = X^{\nu}
\end{cases}
\]

and so

\[
\begin{cases}
\frac{\partial}{\partial \Lambda_w} \Theta(X^u) = \Theta(X^u), \\
\frac{\partial}{\partial \Lambda_w} \Theta(X^{\nu}) = \Theta(X^{\nu}).
\end{cases}
\]
Because \( v_0 + \bar{u}_0 = u_0 - 1 + \bar{u}_0 = n + 1 \), one has
\[
\Theta(X^v) \cap \Theta(X^u) = 0.
\]

Differentiating with respect to \( \Lambda_v \),
\[
o = \frac{\partial}{\partial \Lambda_v} (\Theta(X^v) \cap \Theta(X^u) + \Theta(X^v) \cap \frac{\partial}{\partial \Lambda_u} (\Theta(X^u)))
\]
whence
\[
o = \Theta(X^v) \cap \Theta(X^u) + \Theta(X^v) \cap \Theta(X^u).
\]

**Q. E. D.**

**Lemma 10.** — Let \( a \) be the least integer with \( ad \geq n + 2 \). Every admissible exponent system \( u \) is connected to an admissible \( v \) having \( v_0 = a \).

**Proof.** — It follows from the definition of admissible that \( u_0 \geq a \).
Consider all \( n + 2 \)-tuples \( t = (t_1, \ldots, t_{n+2}) \) of integers satisfying
\[
o \leq t_i \leq u_i - 1 \quad \text{for } i = 1, \ldots, n + 2.
\]
As \( t \) varies over such systems, the function \( \sum t_i \) assumes all integral values from \( o \) to \( \sum (u_i - 1) \). Because
\[
\sum_{i=1}^{n+2} (u_i - 1) = du_0 - (n + 2) \geq du_0 - ad,
\]
there exists a \( t \) as above having \( \sum t_i = d(u_0 - a) \). The desired \( v \) is \( u - t \).

**Q. E. D.**

**Lemma 11.** — If \( n \geq 1 \) and \( d \geq 3 \), then either \( n + 1 \geq 2a \) or \( n = 2 \) and \( d = 3 \).

**Proof.** — Suppose \( n + 1 < 2a \). As \( n \geq 1 \), we have \( a \geq 2 \). As \( n + 2 \geq (a - 1)d \) by definition of \( a \), we have \( 2a \geq n + 2 > (a - 1)d \), so \( 2a/a - 1 > d \geq 3 \), or \( a/a - 1 > 3/2 \), possible only if \( a = 2 \). Then \( d < 2a/a - 1 \) gives \( d = 3 \). Finally, \( 2a \geq n + 2 > (a - 1)d \) gives \( n = 2 \).

**Q. E. D.**

**Lemma 12.** — Suppose \( n + 1 \geq 2a \). Then any two admissible exponent systems \( u \) and \( v \) having \( u_0 = v_0 = a \) are connected to a common admissible exponent system \( w \).

**Proof.** — For \( 1 \leq i \leq n + 2 \), put \( r_i = \max(u_i, v_i) \). We have \( 1 \leq r_i \leq d - 1 \).
If \( \sum r_i \) is divisible by \( d \), take \( \omega = (r_1, \ldots, r_{n+2}) \); if not, there are positive integers \( e \) and \( f \) with
\[
\sum_{i=1}^{n+2} r_i = de - f, \quad 1 \leq f \leq d - 1.
\]
We can take
\[ w = (r_1 + t_1, r_2 + t_2, \ldots, r_{n+2} + t_{n+2}) \]
if we can find \((t_1, \ldots, t_{n+2})\) satisfying \(0 \leq t_i \leq d - 1 - r_i\) and \(\sum t_i = f\).

As \((t_1, \ldots, t_{n+2})\) varies over all \(n+2\)-tuples satisfying only \(0 \leq t_i \leq d - 1 - r_i\), the function \(\sum t_i\) assumes all integral values between 0 and
\[
\sum_{i=1}^{n+2} (d - 1 - r_i) = (n + 2) (d - 1) - \sum_{i=1}^{n+2} r_i.
\]

Because \(u_i \geq 1\) and \(v_i \geq 1\), \(r_i = \max(u_i, v_i) \leq u_i + v_i - 1\).

Thus \(\sum_{i=1}^{n+2} r_i \leq du_v + dv_u - (n + 2) = 2ad - (n + 2)\), and so
\[
(n + 2) (d - 1) - \sum_{i=1}^{n+2} r_i \geq (n + 2) (d - 1) - 2ad + (n + 2)
\]
\[
= (n + 2) d - 2ad = (n + 1 - 2a) d - d \geq d.
\]

Hence there exists \((t_1, \ldots, t_{n+2})\) with
\[ 0 \leq t_i \leq d - 1 - r_i \quad \text{and} \quad \sum_{i=1}^{n+2} t_i = f. \]
