THE GENERALIZED WEIERSTRASS-TYPE INTEGRAL

\[ \int f(\zeta, \varphi) \]

by GARTH WARNER

Introduction.

In a recent paper [5] Cesari showed (5, p. 111) that the Weierstrass-type integrals \( \int f(\mathcal{V}, \varphi) \) relative to a mapping (variety) \( \mathcal{V}: A \to E^n \) and a set function \( \varphi \) which is quasi-additive and of bounded variation with respect to a mesh function \( \delta \) can be obtained by a standard process of limit as \( \delta(D) \to 0 \). Indeed, Cesari showed under general assumptions on \( \mathcal{V} \) and \( f \) that the set function \( \Phi = f(\mathcal{V}, \varphi) \) is again quasi-additive and of bounded variation with respect to the same mesh function \( \delta \), and hence \( \int f(\mathcal{V}, \varphi) \) can be defined as a Burkill-Cesari integral \( \int f(\mathcal{V}, \varphi) = \int \Phi \). In a second paper [6] Cesari proved, under a convenient system of axioms, that \( \int f(\mathcal{V}, \varphi) \) can be represented as a Lebesgue-Stieltjes integral, i.e. \( \int f(\mathcal{V}, \varphi) = (A) \int f(\mathcal{V}, \beta) \, d\mu \) in a certain measure space \( (A, \mathcal{B}, \mu) \).

The main purpose of this paper is to continue the axiomatic approach of Cesari's and to present in an abstract and general setting some of the main properties of the generalized Weierstrass-type integrals \( \int f(\mathcal{V}, \varphi) \). In an earlier paper [12], we carried out this program for the general Burkill-Cesari integral. For the sake of continuity, we adopt the notations and conventions introduced there.

Pervenuto alla Redazione il 14 Settembre 1967

1. Annali della Scuola Norm. Sup. Pisa
In more detail, in this paper generalized Weierstrass-type integrals
\[ \int f(\zeta, \varphi) \] where now both \( \zeta \) and \( \varphi \) are set functions, and \( \varphi \) is quasi-additive and of bounded variation will be investigated. The function \( f \) is assumed to satisfy convenient hypotheses of continuity but \( f \) is not assumed to be real valued. In fact \( f \) and \( \zeta \) take on values in general locally convex topological vector spaces while the range of \( \varphi \) is assumed to be a uniformly convex Banach space. In Section 1, we show that the set function \( \Phi = f(\zeta, \varphi) \) is again quasi-additive and of bounded variation with respect to the same directed set \( (T, \succ) \), and hence \( \int f(\zeta, \varphi) = \int \Phi \) is again a Burkill-Cesari integral. Thus this result represents an extension of a main theorem [5, p. 111] of Cesari’s to the general setting. In Section 2, we discuss the question of the invariance of \( \int f(\zeta, \varphi) \) with respect to change of the generating set functions \( (\zeta, \varphi) \). The results obtained extend those of Stoddart [8]. In Section 3 we consider the question of approximation of the integral \( \int f(\zeta, \varphi) \).

That is, using a convenient notion of convergence of a net of pairs \( (\zeta_\alpha, \varphi_\alpha) \) to a pair \( (\zeta, \varphi) \), we give conditions which enable us to conclude that \( \int f(\zeta_\alpha, \varphi_\alpha) \to \int f(\zeta, \varphi) \). The results obtained extend those proved by Cesari in surface area theory, and show, therefore, that also these results hold in the present axiomatic treatment. In Section 4, we prove an abstract Fubini theorem for the integral \( \int f(\zeta, \varphi) \) which generalizes a result found by Nishiura [7]. In Section 5, the difficult question of the semi-continuity of « regular » integrals is taken up. Under the assumption of regularity on the integrand \( f \) together with a suitable notion of convergence, an abstract semi-continuity theorem for the integral \( \int f(\zeta, \varphi) \) is given. Here, of course, \( f \) is real valued, while it is assumed that \( \zeta, \varphi \) take on values in a Hilbert space \( H \). It should be pointed out, that no representation theorem for the integral \( \int f(\zeta, \varphi) \) as a Lebesgue-Stieltjes integral in a measure space \( (A, B, \mu) \) is used; the semi-continuity is proved directly for the integral \( \int f(\zeta, \varphi) \) as a Burkill-Cesari integral. As corollaries, one obtains a classical theorem due to Tonelli as well as the more recent result of Turner’s [9].

The results given in this paper are contained in the author’s doctoral dissertation submitted in partial fulfillment of the requirements for the degree of Doctor of Philosophy in the University of Michigan, 1966. The author would like to thank Professor L. Cesari, under whose direction the dissertation was written, for his kind advice and encouragement.
1. Existence of the integral $\int f(\zeta, \varphi)$. Let $F$ be a uniformly convex Banach space. Let $E$ and $G$ be Hausdorff locally convex topological vector spaces with topologies described by the collections of semi-norms $\{P_U : U \in \mathcal{U}\}$ and $\{R_W : W \in \mathcal{V}\}$ respectively. $S^1$ will denote the unit sphere in $F$, whereas for $U \in \mathcal{U}$, $e \in E$, we shall put $E_U = \{e : P_U(e) = 1\}$ with a similar meaning for $G_W$, $W \in \mathcal{V}$. The following conventions will be adhered to throughout this paper unless the contrary is explicitly stated. (We shall assume the reader is familiar with the concepts and notation of our earlier paper on this subject [12]).

A will denote a given set, or space, and $\{I\}$ will denote a collection of subsets $I$ of $A$. $\mathcal{F}$ will denote a collection of interval functions $\varphi$ where $\varphi : \{I\} \to F$. $\mathcal{G}$ will denote a collection of interval functions $\zeta$ where $\zeta : \{I\} \to \mathcal{P}(E)$ ($\mathcal{P}(E)$ being as usual the set of all subsets of $E$; hence $\zeta$ is «multiple valued»). We assume there exists a fixed set $T$ such that with each $\varphi \in \mathcal{F}$ one may associate a partial ordering $\gg = \gg (\varphi)$ of $T$ in such a way that $(T, \gg (\varphi))$ is a directed set. With each $t \in T$ there is to be associated a finite collection of disjoint (or non-overlapping) intervals $C_t = [I_1, \ldots, I_N]$ and an operator $L_t$ which is a finite sum, that is, $L_t = \sum_{t \in C_t}$. The action of $L_t$ will be prescribed below.

Let us recall that a Banach space $F$ is said to be uniformly convex if for each $\varepsilon$ with $0 < \varepsilon < 2$ there is some $\delta = \delta (\varepsilon) > 0$ such that $||x - y|| \geq \varepsilon$ implies $\left\| \frac{1}{2} (x + y) \right\| < 1 - \delta/2$ whenever $||x|| = ||y|| = 1$. The following estimate will prove to be useful

(1.1) **Lemma.** Let $F$ be a uniformly convex Banach space. Let $\varepsilon$, $0 < \varepsilon \leq 2$, be given. Let $\{\varphi_i : i = 1, \ldots, n\}$ and $\{\varphi'_j : j = 1, \ldots, m\}$ be two sets of vectors in $F$. Define $\alpha_i = \varphi_i/||\varphi_i||$ for $\varphi_i \neq 0$, any unit vector otherwise, and similarly $\alpha'_j$. Let $J$ be a mapping from $\{1, \ldots, n\}$ into the subsets of $\{1, \ldots, m\}$. Denote by $\Sigma^i$ a sum of terms over $j$ for which $j \in J(i)$, by $\Sigma'_{i}$ a sum of terms over $j$ for which $j \notin J(i)$ and $||\alpha_i - \alpha'_j|| \geq \varepsilon$, and by $\Sigma''_{i}$ a sum of terms over $j$ for which $j \notin J(i)$ and $||\alpha_i - \alpha'_j|| < \varepsilon$. Then there exists a positive number $K = K (\varepsilon)$ such that

$$\varepsilon^2/2K^2 \Sigma^i ||\varphi'_j|| \leq \Sigma^i ||\varphi_i - \Sigma'_{i} \varphi'_j|| + \Sigma_{i} ||\varphi_i|| - \Sigma''_{i} ||\varphi'_j||.$$  

**Proof.** Let $\varepsilon$, $1 \leq i \leq n$, be fixed. Invoking the Hahn-Banach theorem, let $z$ be an element of $F^*$ such that $z (\varphi_i) = ||\varphi_i||$ and $||z|| = 1$. Since $F$ is uniformly convex, there exists $\delta = \delta (\varepsilon)$ such that in particular $||\alpha_i - \alpha'_j|| \geq \varepsilon$ implies $\left\| \frac{1}{2} (\alpha_i + \alpha'_j) \right\| < 1 - \delta/2$. Pick $K > 0$ so that $\varepsilon^2/2K < \delta/2$. 

Note that if \( \| x \| \leq 1 - \delta/2 \), then \( | x(x) | < 1 - \epsilon/2K \). Thus, if \( \| a_i - a_j \| \geq \epsilon \), then
\[
2\sqrt{\frac{1}{2}} (a_i + a_j) = 2\sqrt{\frac{1}{2}} (q_i/v_{q_i} + q_j/v_{q_j}) \\
< 2 \left[ 1 - \epsilon/2K \right] = 2 - \epsilon/K.
\]
Therefore,
\[
\varepsilon (q_i/v_{q_i} - q_j/v_{q_j}) = 1 - \varepsilon(q_j/v_{q_j}) > 1 + \varepsilon/K - 1 = \varepsilon/K.
\]
Squaring both sides and remembering \( \| \varepsilon \| = 1 \) gives
\[
\varepsilon^2 K^{-2} \leq 2 - 2\varepsilon(q_j/v_{q_j}).
\]
Hence
\[
\varepsilon^2 K^{-2} \| q_j \| \leq \| q_j \| - \varepsilon(q_j).
\]
For any \( j \) whatsoever, it is true that \( 0 \leq \| q_j \| - \varepsilon(q_j). \) Thus we may write
\[
\varepsilon^2 K^{-2} \sum_{i} \| q_i \| \leq \sum_{i} (\| q_j \| - \varepsilon(q_j))
\]
\[
= \sum_{i} \| q_i \| - \| q_i \| + \varepsilon(q_i - \sum_{i} q_j)
\]
\[
\leq \| \sum_{i} \| q_j \| - \| q_i \| + \| q_i - \sum_{i} q_j \|
\]
Summing on \( i \) yields the result.

Note that the number \( K \) so determined depends only on \( \epsilon \) and not on the vectors \( q_i, q_j \). Simple examples show that the lemma fails if the uniform convexity requirement on \( F \) is dropped.

Fix a pair \( (\zeta, \varphi) \in \mathcal{Z} \times \varnothing \). Let \( D \) be a subset of \( E \) with \( U \zeta(I) \subset D \). Let \( f : D \times F \to G \) be a mapping such that:

(\( f_1 \)) For each \( W \in \zeta \) there exists a positive real number \( M_W \) such that \( R_W(f(p, q)) < M_W \) for all pairs \( (p, q) \in D \times S^1 \).

(\( f_2 \)) Given \( W \in \zeta \) and \( \epsilon > 0 \), there exists \( U^* = U^*(\epsilon, W) \) and \( \xi = \zeta(\epsilon, W) > 0 \) such that \( R_W(f(p_1, q_1) - f(p_2, q_2)) < \epsilon \) for \( P \neq (p_1, p_2, q_2) \neq \xi \) and \( \| q_1 - q_2 \| < \xi \) where \( p_1, p_2 \in D, q_1, q_2 \in S^1 \).

(\( f_3 \)) \( f(p, aq) = af(p, q) \) for all \( a \geq 0, p \in D, q \in F \).

By hypothesis \( (f) \) we shall mean \( (f_1), (f_2), \) and \( (f_3) \).

A choice function \( c \) on \( \{ \zeta(I) : I \in I^* \} \) is a function \( c \) such that \( c(\zeta(I)) \in \zeta(I) \) for each \( I \in I^* \). Let \( C \) denote the set of all such choice functions \( c \). We shall assume the set function \( \zeta \) is subject to a condition \( (\zeta) \).

(\( \zeta \)) For each \( \epsilon > 0 \) and each \( U \in \mathcal{U} \), there exists \( t' = t'(\epsilon, U) \in T \) such that for every \( t_0 \gg t' \) there exists \( t'' = t''(\epsilon, U, t_0) \) such that if \( t > t'' \),
We point out that in condition (~) the ordering « »» being used is >> (φ). For arbitrary \( c \in \mathbb{C} \) consider the set function
\[
\Phi_c (I) = f (c \zeta (I), \varphi (I)), \quad I \in \mathcal{I}.
\]

If the limit
\[
\lim_{\mathcal{I} \in \mathcal{C}_1} \sum_{I \in \mathcal{I}} \Phi_c (I) = \lim_{\mathcal{I} \in \mathcal{C}_1} \sum_{I \in \mathcal{I}} f (c \zeta (I), \varphi (I))
\]
exists, we denote this limit by \( \int f (c \zeta, \varphi) \). Needless to say, the ordering of \( T \) used in taking the limit is >> (φ). The main existence theorem for the integral is

(1.i) **Theorem.** Suppose \( \varphi \) is quasi-additive and of bounded variation, that is, \( V = V (\| \varphi \|) < + \infty \). If conditions (~) and (f) hold, then \( \Phi_c (I) = f (c \zeta (I), \varphi (I)) \) is quasi-additive and of bounded \( W \)-variation for each \( W \in \mathcal{A} \). Therefore, if \( \mathcal{G} \) is complete, the \( B - C \) integral of \( \Phi_c \) exists; that is,
\[
\int \Phi_c = \int f (c \zeta, \varphi) = \lim_{\mathcal{I} \in \mathcal{C}_1} \sum_{I \in \mathcal{I}} f (c \zeta (I), \varphi (I)).
\]

Furthermore, for arbitrary \( c_1, c_2 \in \mathbb{C} \) we have
\[
\int f (c_1 \zeta, \varphi) = \int f (c_2 \zeta, \varphi),
\]
that is, the value of the integral is independent of the choice function \( c \).

**Proof.** We first prove that \( \Phi_c \) is quasi-additive. Let \( \varepsilon, 0 < \varepsilon \leq 1 \) and \( R_W \) be given. We know from [12, 3. vii] that \( \| \varphi \| \) is quasi-additive. Hence there exists \( t^0_1 = t^0_1 (\varepsilon) \) such that for every \( t_0 > t^0_1 \) there is also \( t_1 = t_1 * (t_0) \) such that \( t >> t_1 * \) implies
\[
\sum_{I \in \mathcal{C}_0} \| \varphi (I) - \sum_{I \in \mathcal{C}_0} \| \varphi (I) \| \leq \varepsilon, \quad \sum_{I \in \mathcal{C}_0} \| \varphi (I) \| \leq \sum_{I \in \mathcal{C}_0} \| \varphi (J) \| \leq \varepsilon,
\]
and
\[
\sum_{I \in \mathcal{C}_0} \| \varphi (J) \| \leq \varepsilon.
\]
Moreover, since \( \int \| \varphi \| \) exists, there exists \( t_*= t_*(\varepsilon) \) such that \( t >> t_\ast \) implies
\[
\left| \sum_{I \in \mathcal{G}_1} \| \varphi(I) \| - V \right| < \varepsilon.
\]

The conditions on \( f \) give \( M_W > 0 \), \( U^* \in \mathcal{U} \), \( \xi = \xi(\varepsilon, W) > 0 \) such that
\[ R_W(f(p_1, q_1)) - f(p_2, q_2) < \varepsilon \text{ for } P_U \ast (p_1 - p_2) < \xi \text{ and } \| q_1 - q_2 \| < \xi \text{ where } p_1, p_2 \in D, q_1, q_2 \in S^1. \]

Condition (\( \zeta \)) gives, for this \( \varepsilon \) and \( U^* \in \mathcal{U}_t \), \( t' \) such that for every \( t_0 >> t' \) there exists \( t'' \) such that if \( t >> t'' \), if \( c, c' \in C, J \subset I, I \in C_0, J \subset C_1 \), then
\[ P_U \ast (c\zeta(J) - c'\zeta(J)) < \varepsilon \text{ and } P_U \ast (c\zeta(J) - c'\zeta(J)) < \varepsilon. \]

Let \( K = K(\xi, W) \) denote the number determined in Lemma (1.1).
Now take \( t^* \in T \) such that \( t^* >> [t'(\xi, W)), t^*_1(e), t^*_1(\varepsilon, W) K^{-2}] \)
and take any \( t_0 >> t^* \). Let \( t_\ast = t_\ast(\varepsilon, R_W, t_0) >> [t_1(e, W) K^{-2}, t_0, t_1(e, t_0), t_0(e), t_1'(< \xi(e, W), t_0)]. \)
Take any \( t >> t_\ast \), and let \( C_1 = [J], C_0 = [I]. \)
Denote by \( \Sigma_I \) a sum over all \( I \in C_0 \) by \( \Sigma_J \) a sum over all \( J \in C_1 \). Denote by \( \Sigma'^I(J) \) the sum over \( J \subset I \) for which \( \| \zeta(J) - \zeta(J) \| \geq \xi \), and by \( \Sigma'^I(J) \) the corresponding sum for which \( \| \zeta(J) - \zeta(J) \| < \xi \). Then we have
\[
\Sigma_I R_W(f(c\zeta(I), \varphi(I)) - \Sigma'^I(J) f(c\zeta(J), \varphi(J)))
\]
\[
= \Sigma_I R_W(f(c\zeta(I), \alpha(I))) \| \varphi(I) \| - \| \Sigma'^I(J) f(c\zeta(J), \alpha(J)) \| \varphi(J) \|
\]
\[
+ \| \Sigma'^I(J) f(c\zeta(I), \alpha(I)) \| \varphi(J) \| - \| \Sigma'^I(J) f(c\zeta(J), \alpha(J)) \| \varphi(J) \|
\]
\[
\leq \Sigma_I R_W(f(c\zeta(I), \alpha(I))) \| \varphi(I) \| - \Sigma'^I(J) \| \varphi(J) \|
\]
\[
+ \Sigma_I (\Sigma'^I(J) + \Sigma'^I(J) R_W(f(c\zeta(I), \alpha(I)) - f(c\zeta(J), \alpha(J))) \| \varphi(J) \|
\]
\[
< M_W \Sigma_I \| \varphi(I) \| - \Sigma'^I(J) \| \varphi(J) \| + \varepsilon \Sigma_I \| \varphi(I) \| + 4M_W K^2 \xi^{-2}(\varepsilon, W)[\Sigma_I \| \varphi(I) \| - \Sigma'^I(J) \| \varphi(J) \| + \Sigma_I \| \varphi(I) \| - \Sigma'^I(J) \| \varphi(J) \|]
\]
\[
< (9M_W + V + \varepsilon) \varepsilon.
\]

Also
\[
\Sigma' R_W(f(c\zeta(J), \varphi(J))) = \Sigma' R_W(f(c\zeta(J), \alpha(J)) \| \varphi(J) \|
\]
\[
\leq M_W \Sigma' \| \varphi(J) \| < M_W \varepsilon.
\]
Since $\epsilon$ is arbitrary, $\Phi_\epsilon$ is quasi-additive as contended, and, if $G$ is complete, $\int \Phi_\epsilon$ exists in view of [12, 3. v].

In order to see that $\Phi_\epsilon$ is of bounded $W$-variation, first observe that hypothesis $(f)$ may be applied to $R_W \circ f$ for each $W \in W$ and consequently $R_W \circ \Phi_\epsilon$ is quasi-additive. Moreover for any $t_0 \in T$,

$$\sum_I (R_W \circ \Phi_\epsilon)(I) = \sum_I R_W (f(c(I), \varphi(I)))$$

$$= \sum_I R_W (f(c(I), \alpha(I))) \| \varphi(I) \| < M_W \sum_I \| \varphi(I) \|.$$

Since $R_W \circ \Phi_\epsilon$ is quasi-additive, $\int R_W \circ \Phi_\epsilon$ exists; in fact, $\int R_W \circ \Phi_\epsilon < M_W V$ and so $\Phi_\epsilon$ is of bounded $W$-variation for each $W \in W$. As a consequence, observe that if the $M_W$'s are uniformly bounded, that is, if there exists $M > 0$ such that $M_W < M$ for all $W \in W$, then $\Phi_\epsilon$ is of bounded variation and $V(\Phi_\epsilon) < MV$.

The fact that $\Phi_\epsilon$ is independent of $c \in C$ follows by a standard "$\epsilon/3$" argument and thus the proof of the theorem is complete.

As mentioned before, (1.ii) represents an extension of a result of Cesari's [5, p. 111]; (1.ii) also contains a generalization of Cesari's result due to Stoddart [8, p. 45].

2. Invariance of $\int f(\zeta, \varphi)$. Given pairs of interval functions $(\zeta, \varphi), (\zeta', \varphi')$ one may ask for conditions under which the corresponding integrals $\int f(\zeta, \varphi), \int f(\zeta', \varphi')$ have the same value. This question was discussed by Stoddart [8] who in turn was motivated by Cesari's treatment of the invariance of surface integrals under Fréchet equivalence. The theorems obtained represent extensions to our setting of similar results established in [8] for $S_\epsilon$-type systems and interval functions $(\zeta, \varphi)$ with finite dimensional range. We shall employ freely and without explicit mention the notations and conventions introduced in the preceding section.

We consider a system $A, \{I\}, (T, >), \zeta$ a map $\zeta: \{I\} \rightarrow \mathcal{P}(E), D \subset E$ and $D \subset \cup \zeta(I)$, while $\varphi: \{I\} \rightarrow F$; and then a second system $A', \{I'\}, (T', >'), \zeta'$ a map $\zeta': \{I'\} \rightarrow \mathcal{P}(E), D \subset E$ and $D \subset \cup \zeta'(I')$, while $\varphi': \{I'\} \rightarrow F$. Let $C$ denote the set of all choice functions $c$ on $\zeta(I): I \in \{I\}, C' = \{c'\}$ denote the set of all choice functions $c'$ on $\zeta'(I')$: $I' \in \{I'\}$. Let $f: D \times F \rightarrow G$ be a map satisfying condition $(f)$.
We already know in view of Theorem (1.ii) sufficient conditions on \((\zeta, \varphi)\) and \((\zeta', \varphi')\) to ensure the existence of the integrals \(\int f(\zeta, \varphi), \int f(\zeta', \varphi')\) as points in \(G\).

We shall say that the pair \((\zeta, \varphi)\) is \((\varphi, \varphi')\)-related to the pair \((\zeta', \varphi')\) (cf. [8, p. 58]) if for each pair \((t_1, t_2) \in T \times T', \epsilon > 0, U \in U\), there exists a map \(m = m(\epsilon, U, t_1, t_2) : A \to S'\) and a pair \((t, t') \in T \times T'\) with \(t = t(\epsilon, U, t_1, t_2) \Rightarrow t_2, t' = t'(\epsilon, U, t_1, t_2) \Rightarrow t_2'\) such that

1. For \(mI \subset I', I \in C, I' \in C',\) and all \(e \in C, e' \in C'\) we have \(P_U(e, e') < e,\)

2. (i) \(\sum_{I' \in C'} ||\varphi'(I') - \Sigma(I')|| < e,\)

(ii) \(\sum_{I' \in C'} ||\varphi'(I') - \Sigma(I')|| \varphi(I) || < e,\)

(iii) \(\Sigma^* ||\varphi(I)|| < e,\)

where \(\Sigma(I')\) denotes a sum over all \(I \in C\) such that \(mI \subset I',\) and \(\Sigma^*\) denotes a sum over all \(I \in C\) such that \(mI\) is contained in no \(I' \in C'.\)

(2.i) \(\text{THEOREM.}\) Let \(f : D \times F \to G\) be a map satisfying condition \((f)\). Suppose \((\zeta, \varphi), (\zeta', \varphi')\) are such that \(f(\zeta, \varphi), f'(\zeta', \varphi')\) exist as elements of \(G\), and \(V = \lim_{t \to 0} \sup_{I \in C} ||\varphi(I)|| < +\infty\). Then if \((\zeta, \varphi)\) is \(\varphi\)-related to \((\zeta', \varphi')\), we have

\[\int f(\zeta, \varphi) = \int f(\zeta', \varphi').\]

\(\text{Proof.}\) It is being assumed that the value of \(\int f(\zeta, \varphi)\) or \(\int f(\zeta', \varphi')\) is independent of the choice function \(e \in C\) or \(e' \in C'.\) Hence \(e \in C, e' \in C'.\)

Let \(\epsilon', 0 < \epsilon' < 1,\) and \(W \in \cap U\) be given. The conditions on \(f\) give \(M_W > 0, U \in \cap U, \xi \in \xi(\epsilon', W) > 0\) such that \(R_W(f(p, q)) < M_W\) on \(D \times S^1\) and \(R_W(f(p_1, q_1) - f(p_2, q_2)) < \epsilon'\) for \(P_U(p_1, q_1), q_2 \in S^1,\) and \(q_1 - q_2 < \xi\) where \(p_1, p_2 \in D, q_1, q_2 \in S^1.\)

There exists \(t_1 \in T\) such that \(t \Rightarrow t_1\) implies

\[R_W\left(\sum_{I \in C} f(\zeta(I), \varphi(I)) - \int f(\zeta, \varphi)\right) < \epsilon'.\]
There exists \( t'_1 \in T' \) such that \( t' \gg t'_1 \) implies

\[
R_W \left( \sum_{t \in T} f(t', \zeta'(I'), \varphi'(I')) - \int f(\zeta, \varphi') \right) < \varepsilon'.
\]

There exists \( t_2 \in T \) such that \( t \gg t_2 \) implies

\[
\sum_{t \in T} \| \varphi(I) \| < V + \varepsilon'.
\]

Let \( K = K(\xi(\varepsilon', W)) \) denote the number determined in Lemma (1.1). Let \( \varepsilon = \min(\varepsilon', \xi(\varepsilon', W), \varepsilon' \xi(\varepsilon', W) K^{-2}) \) and let \( t_{{e'}} \gg [t_1, t_2], t'_{{e'}} \gg t'_1 \). Use \( \varepsilon \) and the pair \((t_{{e'}}, t'_{{e'}})\) in relation above to get a map \( m : A \to A' \) and a pair \((t, t') \in T \times T'\) with \( t \gg t_{{e'}}, t' \gg t'_{{e'}} \) such that (1), (2) are verified. We now have

\[
R_W \left( \sum_{t \in T} f(t', \zeta'(I'), \varphi'(I')) - \sum_{t \in T} f(\varepsilon, \zeta(I), \varphi(I)) \right)
\]

\[
\leq \sum_{t \in T} R_W \left( f(t', \zeta'(I'), \varphi'(I')) \right) \left[ \| \varphi'(I') \| - \sum_{t \in T} \| \varphi(I) \| \right]
\]

\[
+ \sum_{t \in T} R_W \left( f(\varepsilon, \zeta(I), \varphi(I)) \right)
\]

\[
\leq M_W \sum_{t \in T} \| \varphi'(I') \| - \sum_{t \in T} \| \varphi(I) \| + \varepsilon \sum_{t \in T} \| \varphi(I) \|
\]

\[
+ 4M_W K^2 \xi^{-2} (\varepsilon') \sum_{t \in T} \left( \| \varphi'(I') \| - \sum_{t \in T} \varphi'(I') \right)
\]

\[
+ \| \varphi'(I') \| - \sum_{t \in T} \| \varphi(I) \| + M_W \sum_{t \in T} \| \varphi(I) \|
\]

\[
< (10 M_W + V + \varepsilon') \varepsilon'.
\]

So

\[
R_W \left( \int f(\zeta, \varphi') - \int f(\zeta, \varphi) \right) < (10 M_W + V + 2 + \varepsilon') \varepsilon'.
\]

Since \( \varepsilon' \) is arbitrary, \( W \in \mathcal{W} \) is arbitrary, and \( G \) is Hausdorff, we conclude that

\[
\int f(\zeta, \varphi') = \int f(\zeta, \varphi)
\]

as asserted.

By way of applications, we point out that it is not very hard to prove that with respect to suitable interval functions \( \zeta, \varphi \) and sets \( A, I', T \) that
Fréchet equivalent parametric curves stand in relation if the map \( m \) is requested to be a homeomorphism. The same is true for Fréchet equivalent parametric surfaces although the details are more involved here. We refer the reader to [8] for the proofs of these assertions.

One may also discuss «rotational properties» of integrals \( \int f(\zeta, \varphi) \).

This problem arises classically when the interval functions \( (\zeta, \varphi) \) are generated from a variety in \( E^m \), that is, a mapping \( S: A \rightarrow E^m \). Any orthogonal transformation \( L: E^m \rightarrow E^m \) will give a second variety \( S' = LS \) in \( E^m \), with will generate corresponding \( (\zeta', \varphi') \) and often \( \succ (\varphi') \) (cf. [10, p. 923] and [8, pp. 76-80]). We shall give below a generalization of a result of Stoddart [8, p. 77] to our setting.

Let \( N: F \rightarrow F \) be a linear, bijective distance preserving map of \( F \) onto itself. Let \( M: E \rightarrow E \) be a unimorphy, that is, a linear, bijective map of \( E \) onto itself such that for each \( U \subseteq U \), all \( e_1, e_2 \in E \) we have \( P_U(e_1, e_2) = = P_U(e_1, e_2) \). Relative to a system \( A, \{I_i\}, T \), we shall consider interval functions \( \zeta, \zeta' \) from \( \{I_i\} \) to \( \mathcal{P}(E) \), interval functions \( \varphi, \varphi' \) from \( \{I_i\} \) to \( F \), and orderings of \( T; \succ = \succ (\varphi), \succ' = \succ (\varphi') \). Let \( D \subseteq E \) be such that \( D \supset U \zeta(I), D \supset U M^{-1} \zeta'(I) \). Let \( f: D \times F \rightarrow G \) be a map satisfying condition \((f)\). We shall say that the pair \((\zeta, \varphi)\) is \( \varphi(M, N) \) related to the pair \((\zeta', \varphi')\) if for each pair \((t_*, t'_*) \in (T, \succ) \times (T, \succ') = T \times T', \) each \( \epsilon > 0 \), and each \( U \subseteq U \) there exists a pair \((t, t') \in T \times T' \), with \( t = t(\epsilon, U, t_*, t'_*) \succ t_* \), \( t' = t'(\epsilon, U, t_*, t'_*) \succ' t'_* \) such that

1. For \( I \in C_t, I' \in C_{t'} \) and all \( c \in C, c' \in C' \) we have \( P_U(c', \zeta'(I')) - M c \zeta(I) \leq \epsilon \).
2. (i) \[
\sum_{I' \in C_{t'}} \| \varphi'(I') \| - N \sum_{I \in C_t} \| \varphi(I) \| \leq \epsilon,
\]
   (ii) \[
\sum_{I' \in C_{t'}} \| \varphi'(I') \| - \sum_{I \in C_t} \| \varphi(I) \| < \epsilon,
\]
   (iii) \[
\sum' \| \varphi(I) \| < \epsilon,
\]

where \( \sum' \) denotes a sum over all \( I \in C_t \) such that \( I \subset I' \), and \( \sum' \) denotes a sum over all \( I \in C_t \) such that \( I \) is contained in no \( I' \subset C_{t'} \).

(2.ii) Theorem. Let \( f: D \times F \rightarrow G \) be a map satisfying condition \((f)\). Define \( g(p, q) = f(M^{-1} p, N^{-1} q) \). Suppose \((\zeta, \varphi), (\zeta', \varphi')\) are such that \( \int f(\zeta, \varphi), \int g(\zeta', \varphi') \) exist as elements of \( G \), and

\[
V = \limsup_{t \in C_t} \| \varphi(I) \| < + \infty.
\]
Then, if $(\zeta, \varphi)$ is $\varrho - (M, N)$ related to $(\zeta', \varphi')$ we have

$$\int f(\zeta, \varphi) = \int g(\zeta', \varphi').$$

Proof. With $m$ the identity map, observe that $(\zeta, \varphi)$ is $\varrho$-related to $(M^{-1} \zeta', N^{-1} \varphi')$. Hence by (2.i),

$$\int f(\zeta, \varphi) = \int f(M^{-1} \zeta', N^{-1} \varphi') = \int g(\zeta', \varphi').$$

3. Approximation of the integral $\int f(\zeta, \varphi)$. It is the purpose of this section to formulate in abstract terms a theorem of approximation for the integral $\int f(\zeta, \varphi)$. The discussion is motivated by Cesari’s treatment in [2, pp. 24-30] of a theorem in the same spirit for surface integrals. We begin with a preliminary estimate.

(3.i) Lemma. Let $\varphi_i : i = 1, \ldots, n_i$; $\varphi'_i : i = 1, \ldots, n_i'$ be two sets of vectors in $F$, $F$ a Hilbert space. Define $\alpha_i = \varphi_i/||\varphi_i||$ for $\varphi_i \neq 0$, any unit vector otherwise and similarly $\alpha_i'$. Suppose $\Sigma_i ||\varphi_i|| < M$. Then

$$\Sigma_i ||\varphi_i|| \cdot ||\alpha_i - \alpha_i'||^2 < 2[M - \Sigma_i \varphi_i \cdot \varphi_i'/||\varphi_i||].$$

Proof. We denote the inner product of two vectors in $F$ with a dot $\cdot$. Observe that

$$1 - \alpha_i \cdot \alpha_i' = \frac{1}{2} [||\alpha_i||^2 - 2\alpha_i \cdot \alpha_i' + ||\alpha_i'||^2] = \frac{1}{2} ||\alpha_i - \alpha_i'||^2.$$ 

Hence

$$||\varphi_i|| \cdot ||\alpha_i - \alpha_i'||^2 = 2 [||\varphi_i|| - \varphi_i \cdot \varphi_i'/||\varphi_i||].$$

and so summing over $i$ gives

$$\Sigma_i ||\varphi_i|| \cdot ||\alpha_i - \alpha_i'||^2 = 2 \Sigma_i [||\varphi_i|| - \Sigma_i \varphi_i \cdot \varphi_i'/||\varphi_i||] < 2[M - \Sigma_i \varphi_i \cdot \varphi_i'/||\varphi_i||]$$

which completes the proof.
It is known that every Hilbert space is uniformly convex. We shall specialize in this section and assume the space $F$ is a Hilbert space. However the other conventions enumerated earlier are in force.

Let $\{\xi_\beta, \varphi_\beta\}: \beta \in \mathcal{L}$ be a net in $\mathcal{L} \times \Phi$, let $\succ \succ \beta$ denote the ordering of $T$ induced by $\varphi_\beta$, let $\mathcal{C}_\beta$ denote the set of choice functions $c_\beta$ on the set $\{\xi_\beta(I): I \in \{I\}\}$, and let $D \subset E$ be such that $\bigcup_{I \in \{I\}} \xi_\beta(I) \subset D$. Let $f: D \times F \to G$ be a map satisfying condition $(f)$. Suppose that the integrals $\mathcal{I} = \int f(\xi, \varphi), \mathcal{J}_\beta = \int f(\xi_\beta, \varphi_\beta), (\beta \in \mathcal{L})$ exist — conditions sufficient to ensure this were given in (1.ii). Then for the purposes of this section, we shall mean by the term the net $(\xi_\beta, \varphi_\beta)$ $f$-converges to $(\xi, \varphi)$ the following:

(3.ii) **THEOREM.** Let $f: D \times F \to G$ be a map satisfying condition $(f)$. Suppose are such that exist and $(\xi_\beta, \varphi_\beta)$ $f$-converges to $(\xi, \varphi)$ and is of bounded variation $V$ and $\varphi_\beta$ respectively, then $\lim \varphi_\beta = \varphi$ provided $\lim V_\beta = V$.

**Proof.** It is being assumed that the value of $\mathcal{I}$ and $\mathcal{J}_\beta$ is independent of the choice function $c \in \mathcal{C}$ or $c_\beta \in \mathcal{C}_\beta$. Hence fix $c \in \mathcal{C}$, $c_\beta \in \mathcal{C}_\beta$ and let
\[ t \in T \text{ be arbitrary. Let } \varepsilon', 0 < \varepsilon' < 1, \text{ and } W \in \mathcal{W} \text{ be given. The conditions on } f \text{ give } M_W > 0, U^* \in \mathcal{L}, \xi = \xi(\varepsilon', W) > 0 \text{ such that } R_W(f(p,q)) < M_W \text{ on } D \times S^1, \text{ and } R_W(f(p_1, q_1) - f(p_2, q_2)) < \varepsilon' \text{ for } p_1, p_2 \in D, q_1, q_2 \in S^1. \]

Let \( \varepsilon = \min(\varepsilon', \bar{\varepsilon}(\varepsilon', W), \varepsilon^2(\varepsilon', W)) \), as above, and take \( W \in \mathcal{W} \) with corresponding \( U^* \in \mathcal{L} \) in the definition of \( f \)-convergence above. Hence, we are provided with \( \beta_0 \) and \( t_0 \) such that conditions (\( f_4 \)) through (\( f_5 \)) above are fulfilled. It may be assumed without loss of generality that \( \beta_0 \) is chosen so that \( \beta > \beta_0 \) implies \( V - V_\beta < \varepsilon \) and \( t_0 \) is chosen so that \( t > t_0 \) implies

\[ V - \varepsilon < \sum_{I \in \mathcal{I}_2} \| \varphi(I) \| < V + \varepsilon. \]

Let \( \beta > \beta_0 \). We shall write \( \Sigma_I \) for any sum over all \( I \in \mathcal{C}_0 \), \( \Sigma_I^+ \) for any sum over all \( I \in \mathcal{C}_0 \) such that \( \| a(I) - a_\beta(I) \| \leq \xi \), \( \Sigma_I^- \) for any sum over all \( I \in \mathcal{C}_0 \) such that \( \| a(I) - a_\beta(I) \| < \xi \). Then we have

\[
R_W(\Sigma_I f(c \xi(I), \varphi(I)) - \Sigma_I f(c \xi_\beta(I), \varphi_\beta(I)))
\]

\[
\leq \Sigma_I R_W(f(c \xi_\beta(I), \varphi_\beta(I))) - \| \varphi \| + \| \varphi_\beta \| |
\]

\[
+ \Sigma_I R_W(f(c \xi(I), \alpha(I)) - f(c \xi_\beta(I), \varphi_\beta(I))) \| \varphi \|
\]

\[
< M_W \Sigma_I |\varphi(I)| - |\varphi_\beta(I)| |
\]

\[
+ \Sigma_I^+ R_W(f(c \xi(I), \alpha(I)) - f(c \xi_\beta(I), \alpha_\beta(I))) \| \varphi \|
\]

\[
+ \Sigma_I^+ R_W(f(c \xi(I), \alpha(I)) - f(c \xi_\beta(I), \alpha_\beta(I))) \| \varphi \|
\]

\[
< M_W \varepsilon' + \varepsilon'(V + \varepsilon') + 2M_W \Sigma_I^+ \| \varphi(I) \|.
\]

It remains to study the last sum in the line above. From (3.i) we have

\[
\Sigma_I^+ \| \varphi_\beta \| \| a(I) - a_\beta(I) \|^2
\]

\[
\leq \Sigma_I \| \varphi_\beta \| \| a(I) - a_\beta(I) \|^2
\]

\[
< 2 [V - \Sigma_I \varphi(I)] \| \varphi_\beta(I) \| \| \varphi_\beta \| |
\]

\[
+ 2 \varepsilon
\]

\[
= 2 [V - \Sigma_I \varphi_\beta(I)] \| \varphi_\beta(I) \| \| \varphi_\beta(I) - \Delta_\beta(I) \| + 2 \varepsilon
\]

\[
< 2 |V - V_\beta| + 2 \| V_\beta - \Sigma_I \| \varphi_\beta(I) \| + 2 \Sigma_I \| \Delta_\beta(I) \| + 2 \varepsilon
\]
where we have written $A(I) = \varphi(\beta(I)) - \varphi(I)$. Observe that
\[ \| \varphi(\beta(I)) \| = \| (\varphi(\beta(I)) - \varphi(I)) + \varphi(I) \| \geq \| \varphi(I) \| - \| \varphi(\beta(I)) - \varphi(I) \|. \]
Hence
\[ -\Sigma \| \varphi(\beta(I)) \| \leq \Sigma \| \varphi(\beta(I)) - \varphi(I) \| - \Sigma \| \varphi(I) \| < 2\epsilon - V \]
and so
\[ V - \Sigma \| \varphi(\beta(I)) \| < 2\epsilon. \]
Similarly
\[ \Sigma \| \varphi(\beta(I)) \| - V < 2\epsilon. \]
We conclude that
\[ | V - \Sigma \| \varphi(\beta(I)) \| | < 2\epsilon. \]
Then
\[ | V - \Sigma \| \gamma(\beta(I)) \| | \leq | V - V_{\beta} | + | V - \Sigma \| \gamma(\beta(I)) \| | < 3\epsilon, \]
and so
\[ \Sigma \| \gamma(\beta(I)) \| \Sigma \| \alpha(I) - \alpha(\beta(I)) \| < 2\epsilon + 6\epsilon + 2\epsilon + 2\epsilon = 12\epsilon. \]
Consequently
\[ \xi^{-2} \Sigma \| \gamma(\beta(I)) \| \xi^{-2} \leq \xi^{-2} \Sigma \| \gamma(\beta(I)) \| \Sigma \| \alpha(I) - \alpha(\beta(I)) \| < 12\epsilon \xi^{-2} < 12\epsilon'. \]
Thereby
\[ R_W(\Sigma f(c \xi(I), \varphi(I))) - \Sigma f(c \xi(I), \varphi(I)) < M_W \epsilon' + \epsilon'(V + \epsilon') + 24M_W \epsilon' = \epsilon'(25M_W + V + \epsilon'). \]
Writing
\[ R_W(\mathcal{F} - \mathcal{F}_\beta) \]
\[ \leq R_W(\mathcal{F} - \Sigma f(c \xi(I), \varphi(I))) + R_W(\mathcal{F}_\beta - \Sigma f(c \xi(I), \varphi(I))) \]
\[ + R_W(\Sigma f(c \xi(I), \varphi(I))) - \Sigma f(c \xi(I), \varphi(I))) \]
\[ < \epsilon'(25M_W + V + 2 + \epsilon'), \]
we deduce, since $\epsilon'$ is arbitrary, $W \in \mathcal{O}^3$ is arbitrary, and $\mathcal{G}$ is Hausdorff, that $\lim \mathcal{F}_\beta = \mathcal{F}$ as asserted. This completes the proof of the theorem.

Observe that we may take as a particular case the special map $f: \mathcal{D} \times F \to F$ defined by $f: (p, q) \to q$ then, under the other conditions, infer that $\lim \int f = \int f$.

Let us now sketch briefly an illustration of Theorem (3.ii). Let $S = (S, A), S_n = (S_n, A), n = 1, 2, \ldots$, be continuous mappings of finite Lebes-
gue area $L(S, A)$ respectively. Let $[S]$, $[S_n]$ denote the graphs of $S$, $S_n$ respectively and suppose $[S]$, $[S_n] \subset D \subset \mathbb{R}^3$. Let $f(p, q)$, $p = (p_1, p_2, p_3) \in D$, $q = (q_1, q_2, q_3) \in \mathbb{R}^3$ be a real valued function defined on $D \times \mathbb{R}^3$ such that $f(p, aq) = af(p, q)$ for all $a \geq 0$, $p \in D$, $q \in \mathbb{R}^3$, let $U = \{q \in \mathbb{R}^3, \|q\| = 1\}$ be the unit sphere in $\mathbb{R}^3$ and suppose $f$ is bounded and uniformly continuous on $D \times U$. Consider the following proposition (P) [4, p. 571]:

(P) Let $f$ be as above. Let $S = (S, A)$, $S_n = (S_n, A)$, $n = 1, 2, \ldots$, be continuous mappings of finite Lebesgue area. Suppose $S_n \to S$ uniformly, $L(S_n, A) \to L(S, A)$ as $n \to \infty$. Then we have also $\lim (S_n) \int f = (S) \int f$.

Now actually this proposition follows from (3.ii) For given a closed simple polygonal region $I \subset A$, we define $\zeta(I) = \bigcup_{w \in I} S(w)$, $\zeta_n(I) = \bigcup_{w \in I} S_n(w)$, $n = 1, 2, \ldots$. Take for $\varphi(I)$, $\varphi_n(I)$ the interval functions defined in [5, p. 106]. Recall that $\varphi$, $\varphi_n$ are quasi-additive with respect to certain mesh functions $\delta$, $\delta_n$ relative to finite systems $D$ of nonoverlapping polygonal regions $I$. Hence the integrals $\int f(\zeta, \varphi)$, $\int f(\zeta_n, \varphi_n)$ exist. Since the variations of $\varphi, \varphi_n$ are nothing more than the Lebesgue areas of the surfaces $(S, A)$, $(S_n, A)$ and since by assumption $\lim L(S_n, A) = L(S, A)$, we need only verify that

$(\zeta_n, \varphi_n) f$ converges to $(\zeta, \varphi) f$. The $f$ convergence follows since, under the conditions of proposition (P), for arbitrary $\epsilon > 0$ Cesari has shown ([1, p. 1385]; [3]) that one may find a finite system $D_n = \{I\} = \{I_1, \ldots, I_m\}$ of nonoverlapping polygonal regions $I \in \{I\}$ and an integer $N_1$ such that

\[
(f_1)_p \quad \delta(D_n) < \epsilon, \delta_n(D_n) < \epsilon \quad \text{for all } n > N_1;
\]

\[
(f_2)_p \quad \text{For all } n > N_1
\]

\[
\sum_{I \in D_n} \|\varphi_n(I) - \varphi(I)\| < \epsilon.
\]

Then, in view of the uniform convergence of $\{S_n\}$ to $S$, and simple but technical considerations of surface area theory, one may produce an integer $N_0 > N_1$ such that in addition

\[
(f_3)_p \quad \text{For all } n > N_0, \text{ for all } c \in C, c_n \in C_n \text{ for all } I \in D_0 \text{ we have}
\]

\[
\|c \zeta(I) - c_n \zeta_n(I)\| < \epsilon;
\]

\[
(f_4)_p \quad \text{For all } n > N_0, \text{ for all } c \in C, c_n \in C_n,
\]

\[
(i) \quad \sum_{I \in D_0} |f(c \zeta(I), \varphi(I)) - \mathcal{T}| < \epsilon
\]

\[
(ii) \quad \sum_{I \in D_0} |f(c_n \zeta_n(I), \varphi_n(I)) - \mathcal{T}_n| < \epsilon.
\]
These facts are worked out in detail in [2, pp. 27-28]. Hence \((\zeta_n, \varphi_n)\) if \(f\)-convergent to \((\zeta, \varphi)\) and so proposition (P) follows from Theorem (3.2).

We remark that similar considerations may be applied to parametric curves.

4. A Fubini theorem for \(\int f(\zeta, \varphi)\). It is the purpose of this section to supplement the results of Section 4 in [12] by formulating a Fubini type theorem for the integrals \(\int f(\zeta, \varphi)\). The results obtained represent extensions of those in [7].

In what follows \(\times \) will run over 1, 2. Let \(E_i\) be Hausdorff locally convex topological vector spaces with associated families of semi-norms given by \(|P_i| : U_i \in \mathcal{U}_i\). Let \(F_1, F_2\) be Hilbert spaces as in [7] and let \(F = F_1 \otimes F_2\) be their tensor product — thus for \(q_1 \in F_1, q_2 \in F_2, q_1 \otimes q_2 \in F_1 \otimes F_2\), and one has \(\| q_1 \otimes q_2 \| = \| q_1 \| \| q_2 \| \) as in \(F_1, F_2\) respectively. Let \(A_1\) and \(A_2\) be sets with corresponding collections of intervals \(I_1, I_2\). Let \((I_i : i \in (T_i, \triangleright))\) be as usual. Let \(\zeta, \varphi\) be interval functions where \(\zeta : I_1 \rightarrow \mathcal{P}(E_1)\) and \(\varphi : I_1 \rightarrow F_1\). Let \(C_i\) denote the set of all choice functions \(c\) on the collection \(\zeta_i(I_i) : I_i \in I_i^\triangleright\). Let \(D_i \supseteq \cup \zeta_i(I_i)\). Let \((T, \triangleright)\) be the directed set \(T_1 \times T_2\) \(\langle \times \rangle\) meas Cartesian product where \(\langle \rangle\) is the usual product ordering induced by \(\triangleright_1\) \((\varphi_1)\) and \(\triangleright_2\) \((\varphi_2)\). We then define \(A = A_1 \times A_2, I = \{ I_1 \times I_2 \}^\triangleright, C_i = C_i \times C_i, t = (t_1, t_2) \in T\). The space \(E = E_1 \otimes E_2\) is a Hausdorff locally convex topological vector space if we equip it with the topology determined by the semi-norms \(P_i, P_2\) defined by \(P_i : U_i \in \mathcal{U}_i\) \((e_1, e_2) \in E_1 \times E_2\). Define the map \(\zeta : I_i \rightarrow \mathcal{P}(E_1 \times E_2)\) by stipulating \(\zeta(I) = \zeta_i(I_1) \times \zeta_2(I_2)\) for \(I = I_1 \times I_2\). Suppose the maps \(\zeta_i\) satisfy condition \((\zeta_i)\). Then we claim that the product map \(\zeta\) satisfies condition \((\zeta)\) with respect to the collection \((P_i, P_2)\) and the set \((T, \triangleright)\). Indeed, let \(\epsilon > 0\) and \(P_i, P_2\) be given. Since \(\zeta_i\) satisfies condition \((\zeta_i)\), there exists \(t' = t'_{\epsilon/2, U_i} \in (T_1, \triangleright)\) such that for every \(t_0 \triangleright_1 t',\) there exists \(t_0' = t_0_{\epsilon/2, U_i} (t_0, t_0)\) such that if \(t_i, t_0 \in C_i, t_i \in \subseteq I_i, I_1 \in I_1^\triangleright, J_i \in J_i^\triangleright\), then

\[ P_i(c_i, \zeta_i(I_i), \zeta_i(I_i)) < \epsilon/2, P_2(c, \zeta_i(J_i), \zeta_i(J_i)) < \epsilon/2. \]
We see that

\[ P(v_1, v_0) (c \zeta (I) - c' \zeta (J)) = \]
\[ = P(v_1, v_0) ((c_1 \zeta_1 (I_1) - c'_1 \zeta_1 (I_1)), c_2 \zeta_2 (I_2) - c'_2 \zeta_2 (J_2))) \]
\[ P(v_1, v_0) (c_1 \zeta_1 (I_1) - c'_1 \zeta_1 (I_1)) + P(v_2, v_0) (c_2 \zeta_2 (I_2) - c'_2 \zeta_2 (J_2)) < \epsilon. \]

Likewise \( P(v_1, v_0) (c \zeta (J) - c' \zeta (J)) < \epsilon. \) Hence the map \( \zeta \) satisfies condition (\( \zeta \)) as claimed. Next we define by the relation

\[ \varphi = \varphi_1 \otimes \varphi_2 : \mathcal{I}_t \rightarrow \mathcal{F}_t \otimes \mathcal{F}_t \] for the relation \( \varphi (I) = \varphi_1 (I_1) \otimes \varphi_2 (I_2) \) and for \( t = (t_1, t_2) \in \mathcal{T}, \) we let \( L_t (\varphi) = \sum_{t \in \mathcal{O}_t} \varphi (I); \)

observe \( L_t (\varphi) = L_{t_1} (\varphi_1) \otimes L_{t_2} (\varphi_2). \) Recall [12, 4.ii] which asserted that if the \( \varphi_i \) were quasi-additive and of bounded variation, then the product \( \varphi_1 \otimes \varphi_2 \) was also quasi-additive and of bounded variation. Let \( D \subset E_1 \times E_2 \) and suppose \( D_t \subset D. \) Let \( f : D \times F \rightarrow G, G \) a complete Hausdorff locally convex topological vector space whose topology is described by semi-norms \( \{ R_w : W \in \mathcal{C} \}. \) Assuming \( f \) satisfies condition (\( f \)), we know from (1.ii, with

our assumptions on \( \zeta \) and \( \varphi \), that \( \int f (\zeta, \varphi) \) exists. Our problem will be to relate this «double integral» to certain «iterated integrals» which will be defined below.

In the Hilbert space \( \mathcal{F}_t \) denote the sphere of radius \( \alpha \) by \( S^\alpha. \) Let \( f : D \times F \rightarrow G \) and assume \( f \) satisfies condition (\( f \)). Then for each \( W \in \mathcal{W} \) there exists a positive real number \( M \) such that \( R_W (f (p, q)) < M \) for all pairs \( (p, q) \in D \times S^\alpha. \) Let \( q^I \in S^\alpha. \) Writing \( f (p, q^I) = f (p, q^I/\|q^I\|) \|q^I\|, \) we see that \( R_W (f (p, q^I)) < M \) for all pairs \( (p, q) \in D \times S^\alpha. \) Likewise there exists \( P_{t_1}, P_{t_2} \) and \( \xi > \xi (\epsilon, W) > 0 \) such that \( R_W (f (p_1, q_1) - f (p_2, q_2)) < \epsilon \) for \( P_{t_1}, P_{t_2}, \xi \) and \( \|q_1 - q_2\| < \xi \) where \( p_1, p_2 \in D; q_1, q_2 \in S^\alpha. \) If \( q_1^I, q_2^I \in S^\alpha, \) then as above we see that \( R_W (f (p_1, q_1^I) - f (p_2, q_2^I)) < \epsilon \) for \( P_{t_1}, P_{t_2}, \xi \) and \( \|q_1^I - q_2^I\| < \epsilon. \) Keeping these facts in mind, we prove

(4.1). Lemma. Suppose \( f : D \times F \rightarrow G \) satisfies condition (\( f \)).

(a) Let \( (p_1, q_1) \) be a fixed point in \( D_1 \times F_1. \) Then \( g (p_2, q_2) = f (p_2, q_2) \) as a function on \( D_2 \times F_2 \) satisfies condition (\( g \)).

(b) Let \( q_2 : [I_2 \rightarrow F_2 \) be quasi-additive and of bounded variation. Then

\[ l (p_1, q_1) = \int f (p_1, \zeta, q_1 \otimes q_2) \exists \text{ for each } (p_1, q_1) \in D_1 \times F_1. \] Moreover \( l \) regarded as a function on \( D_1 \times F_1 \) satisfies condition (\( l \)).

Proof. By \( \Sigma_n \) we mean a sum over all \( I_n \in O_n. \) Statement (a) is quite clear in view of the remarks preceding the Lemma and the fact that \( \|q_1 \otimes q_2\| = \|q_1\|_1 \|q_2\|_2. \) Let us prove (b). First of all the existence of \( l \) is a conse-
quence of (1.ii). Homogeneity of \( l \) (that is, condition \((l_3)\)) follows since for \( a > 0 \),
\[
a l(p_1, q_1) = a \lim \Sigma_{I_3} f(p_1 \times c_2 \zeta_2(I_3), q_1 \otimes \varphi_2(I_3))
\]
\[
= \lim \Sigma_{I_3} f(p_1 \times c_2 \zeta_2(I_3), aq_1 \otimes \varphi_2(I_3)) = l(p_1, aq_1).
\]

For each \( W \in \mathcal{G}_\beta \) there exists a positive real number \( M_W \) such that
\[
R_W(f(p, q)) < M_W \text{ for all pairs } (p, q) \in D \times S^1.
\]
Hence
\[
R_W(f((p_1, p_2), q_1 \otimes q_2)) < M_W \| q_1 \otimes q_2 \| = M_W \| q_1 \|_1 \| q_2 \|_2.
\]
Therefore
\[
R_W(l(p_1, q_1)) = R_W(\lim \Sigma_{I_3} f(p_1 \times c_2 \zeta_2(I_3), q_1 \otimes \varphi_2(I_3)))
\]
\[
\leq \lim \Sigma_{I_3} R_W(f(p_1 \times c_2 \zeta_2(I_3), q_1 \otimes \varphi_2(I_3)))
\]
\[
\leq \lim \Sigma_{I_3} M_W \| q_1 \|_1 \| q_2 \|_2 \leq M_W \| q_1 \|_1 V(\| q_2 \|_2).
\]
Hence
\[
R_W l(p_1, q_1) \leq M_W V(\| q_2 \|_2)
\]
for all pairs \((p_1, q_1) \in D_1 \times S^1_1\) and so \((l_1)\) is satisfied.

Now there exists \( P(u_1, v_1) \) and \( \xi = \xi(\varepsilon, W) > 0 \) such that
\[
R_W(f(p_1, q_1) - f(p_2, q_2)) < \varepsilon \text{ for } P(u_1, v_1)(p_1 - p_2) < \xi \text{ and } \| q_1 - q_2 \| < \xi \text{ where } p_1, p_2 \in D; \ q_1, q_2 \in S^1.
\]
Hence if \((p_1^{(1)}, q_1^{(1)}), (p_1^{(2)}, q_1^{(2)}) \in D_1 \times S^1_1\) and \( P_1(1 - p_1^{(2)}) < \xi, \| q_1^{(1)} - q_1^{(2)} \|_1 < \xi, \) then
\[
R_W(f((p_1^{(1)}, p_2), q_1^{(1)} \otimes q_2) - f((p_1^{(2)}, p_2), q_1^{(2)} \otimes q_2)) \leq \varepsilon \| q_2 \|_2.
\]
Hence
\[
R_W(l(p_1^{(1)}, q_1^{(1)}) - l(p_1^{(2)}, q_1^{(2)}))
\]
\[
\leq \lim \Sigma_{I_3} R_W(f((p_1^{(1)} \times c_2 \zeta_2(I_3), q_1^{(1)} \otimes \varphi_2(I_3))
\]
\[
- f(p_1^{(2)} \times c_2 \zeta_2(I_3), q_1^{(2)} \otimes \varphi_2(I_3)))
\]
\[
\leq \lim \Sigma_{I_3} \varepsilon \| \varphi_2(I_3) \|_2 = \varepsilon V(\| \varphi_2 \|_2)
\]
and thereby \((l_4)\) is fulfilled. Thus \( l \) regarded as a function on \( D_1 \times F_1 \) satisfies condition \((l)\) as required and this completes the proof of the Lemma.
(4.ii) Theorem. Let \( f : D \times F \to G \) be a map satisfying condition \((f)\). Suppose \( \varphi_i : [I_i] \to F_i \) is quasi-additive and of bounded variation \( V_i \) and that \( \zeta_i : [I_i] \to \mathcal{P}(E_i) \) satisfies condition \((\zeta_i)\). Then, with the other assumptions cited earlier, we have

\[
\begin{align*}
(a) \quad & (A_1) \int f(\zeta, \varphi) \text{ exists; } \\
(b) \quad & l(p_1, q_1) = (A_2) \int f(p_1 \times \zeta_2, q_1 \otimes q_2) \text{ exists for each } (p_1, q_1) \in D_1 \times F_1, \ k(p_2, q_2) = (A_3) \int f(\zeta_1 \times p_2, \varphi_1 \otimes q_2) \text{ exists for each } (\zeta_1 \times p_2, \varphi_1 \otimes q_2) \in D_2 \times F_2. \\
\end{align*}
\]

Moreover, \( l, k \) satisfy conditions \((l), (k)\) respectively;

(c) the iterated integrals exist, that is \((A_4) \int (A_5) \int f(\zeta, \varphi)\) and \((A_6) \int f(\zeta, \varphi)\) exist;

(d) the iterated integrals = the double integral of \((a)\).

Proof. We have commented on \((a)\) above. Statement \((b)\) is Lemma (4.i). Statement \((c)\) follows from \((b)\) and (1, ii); \((d)\) is obvious.

5. Semi-continuity of the integral \( \int f(\zeta, \varphi) \). In this section we shall prove, under appropriate assumptions, an abstract semi-continuity theorem for integrals of the form \( \int f(\zeta, \varphi) \). Usually such theorems are proved for integrals of the form \( \int f(\zeta, \varphi) d\mu \), \( \mu \) being a suitable measure on a measure space \( X \). However, to do this one has to introduce various axioms and obtain a representation theorem for the B-C integral as a Lebesgue integral. Using such a representation of the B-C integral, Stoddart [8] succeeded in establishing a very general theorem of semi-continuity which in turn contained many of the classical results. On the other hand, Turner [9, p. 112] proved directly a semi-continuity theorem for the Cesari-Weierstrass surface integral without recourse to any representation theorem. We shall give a theorem in this direction which, although not entirely analogous to Turner's, is in the same spirit.

Let \( H \) be a real Hilbert space and let \( S^1 \) denote the unit sphere in \( H \). Let \( \{e_i\} \) be an orthonormal basis for \( H \). Let \( H^n \) denote \( H \) equipped with the weak topology. A weak neighborhood \( W \) of a point \( h_0 \in H \) is determined by specifying a number \( \varepsilon > 0 \) and a continuous linear functionals \( z_1, \ldots, z_n \); then \( W = W(h_0 ; z_1, \ldots, z_n, \varepsilon) = \{ h : h \in H \text{ and } | z_i(h) - z_i(h_0) | < \varepsilon, \ i = 1, \ldots, n \} \). It is known that \( H \) and \( H^n \) have the same set of continuous
linear functionals and if \( \varphi \) is such a functional, then there exists a unique
vector \( a \in H \) such that \( \varphi(h) = (h, a) = (a, h) \) for all \( h \in H \) (\( (, ) \) means inner
product in \( H \)). Moreover, regarding \( \varphi \) as an element of \( H^\ast \), \( \| \varphi \| = \| a \| \). Fi-
nally, since \( H \) is reflexive, spheres in \( H \) are weakly compact.

We shall consider a set \( \mathcal{S} \) of pairs \( (\zeta, \varphi) \) where \( \zeta : [I] \to \mathcal{P}(H), \varphi : [I] \to H \)
(so, in our previous notation, we are taking \( E = H, F = H \)). We shall as-
sume that the elements of \( \mathcal{S} \) are « preserved » under isometries. Precisely,
let \( m : H \to H \) be a bounded, linear, bijective map such that if \( h_1, h_2 \in H \),
then \( \| mh_1 - mh_2 \| = \| h_1 - h_2 \| \). Given an arbitrary \( (\zeta, \varphi) \in \mathcal{S} \), let \( \zeta' = m\zeta \)
and suppose that there is associated with \( \zeta' \) a map \( \varphi' : [I] \to H \) such that
\( (\zeta', \varphi') \in \mathcal{S} \). We then assume

\[
(m) \varphi' = m \varphi.
\]

Let \( f : D \times H \to R \), \( R \) the real numbers, \( D \subset H \) to be specified presently.
Conditions \( (f) \) and \( (\zeta) \) are assumed to be in force here for each \( (\zeta, \varphi) \in \mathcal{S} \).
If we let \( D \supset U \cup \zeta(I) \), then condition \( (f) \) now reads : \( (f_1) f \) is bounded on
\( D \times S^1 \); \( (f_2) f \) is uniformly continuous on \( D \times S^1 \); \( (f_3) f(p, aq) = af(p, q) \)
for all \( a \geq 0 \), \( p \in D \), \( q \in S^1 \). For a given pair \( (\zeta, \varphi) \in \mathcal{S} \), it is desirable to be
able to speak of

\[
\mathcal{I}(\zeta, \varphi) : \langle I \rangle \int f(\zeta, \varphi) = \lim_{(T_I, >>_I \varphi \rangle) J \in C_{IE}} \sum_{J \in J_I} f(c \zeta(J), \varphi(J))
\]

for each \( I \in \mathcal{I} \) where \( (T_I, >>_I \varphi \rangle) \) is a certain directed set that is, we
want to consider \( \mathcal{I} \) as a map, \( \mathcal{I} : \mathcal{S} \times [I] \to R \). For this purpose, it is clearly
enough to have at hand a method for extending the definition of the
integral of \( f \) over \( A \) to a corresponding integral of \( f \) over each \( I \in \mathcal{I} \).
In applications this situation always exists. Abstractly such an extension may be
realized by a generalization of the method given by Cesari in [6]. In a future
paper, we shall give the details of this procedure, but for our purposes
here we shall proceed axiomatically and make the following assumptions
(which are consequences of the general extension process):

\[
(P_4) \text{ With each pair } (\zeta, \varphi) \in \mathcal{S} \text{ and with each } I \in \mathcal{I}, \text{ there is associated}
\text{ a directed set } (T_I, >>_I \varphi \rangle \rangle) = (T_I, >>_I \varphi \rangle), \text{ and a collection of intervals}
\text{ } \mathcal{J}_I \subset I, J \in \mathcal{J}_I. \text{ For given } I \in \mathcal{I}, \text{ we assume the set } T_I \text{ and the}
\text{ collection } \mathcal{J}_I \text{ are fixed and independent of the pair } (\zeta, \varphi) \text{ (although } >>_I \varphi \rangle \rangle\text{ will}
\text{ in general depend upon the pair } (\zeta, \varphi). \text{ With each } t_I \in T_I \text{ there is associated}
\text{ a finite collection } C_{t_I} \text{ of intervals } J \in \mathcal{J}_I \text{ and an operator}
L_{t_I} = \Sigma. \text{ It is assumed that for each } (\zeta, \varphi) \in \mathcal{S}, \text{ for each } I \in \mathcal{I},
\]

\[
(I) \quad \int f(\zeta, \varphi) = \lim_{(T_I, >>_I \varphi \rangle) J \in C_{t_I}} \sum_{J \in J_I} f(c \zeta(J), \varphi(J))
\]
exists and is independent of the choice function $c$.

(P2) We shall suppose that if $f(p, q) \geq 0$ for all $(p, q) \in D \times S^1$, then for arbitrary $t \in T$, we have

$$\mathcal{I}(\zeta, \varphi, A) \geq \sum_{I \in \Omega(t)} \mathcal{I}(\zeta, \varphi, I),$$

$(\zeta, \varphi)$ being an arbitrary element of $\mathcal{S}$.

We shall assume that given $(\psi, \varphi) \in \mathcal{S}$, $I \in \Omega(t)$, and any isometry $m$, then the orderings $\gg_I (m \varphi)$ and $\gg_I (\varphi)$ are comparable.

It will prove to be useful to consider « special neighborhood » systems of elements $s_0 = (\zeta_0, \varphi_0)$ in $\mathcal{S}$. Thus, for arbitrary $s_0 \in \mathcal{S}$, it will be said that a net $(s, \alpha \in \mathcal{A}, \triangleright)$ in $\mathcal{S}$ is $M$-convergent to $s_0 \in \mathcal{S}$ if the following conditions are satisfied:

1. For each $\varepsilon > 0$ and $t \in T$, there exists $\alpha_0 = \alpha_0(t, t \triangleright)$ and $t \triangleright = t \triangleright(t, \varepsilon)$ such that for all $\alpha > \alpha_0$:
   - (a) $t \triangleright = \ll (\varphi_0, t \triangleright, t \triangleright = \ll (\varphi_0, t \triangleright);$
   - (b) $c_0 \in C_0, c_0 \in C_0$; for all $I \in C_0$,
     $$||c_0 \tilde{z}_0(I) - c_0 \xi_0(I)|| < \varepsilon$$
     and
     $$\sup_{J \in I} ||c_0 \tilde{z}_0(I) - c_0 \xi_0(j)|| < \varepsilon.$$

2. For each $\varepsilon > 0$, for each $I \in \Omega(t)$, there exists $\alpha_0 = \alpha_0(t, \varepsilon, I)$ such that for each $\alpha > \alpha_0$ there exists $t I = t I(\alpha, \varepsilon)$ such that for every $t I = t I(\alpha, \varepsilon)$ we may find a subsystem $C_0 = C_0 I \subseteq C_0$ satisfying

$$||t I - t I(\alpha, \varepsilon)|| \leq \varepsilon,$$

where $\sum'$ a sum over all $J \in C_0 I$, $e_1$ an element of the orthonormal basis $\{e_1\}$.

We remark that the second condition of $M$-convergence is related to a lemma of McShane used in surface area theory (see [10, p. 923]). Furthermore, the use of a special type of convergence is not new; thus the « $V$-convergence » of [8, p. 89] is in the same spirit as $M$-convergence although quite different in content. Finally we shall assume that isometries preserve $M$-convergence, that is, if $m : H \rightarrow H$ is an isometry and $s_0$ is $M$-convergent to $s_0$ then $m \circ s_0$ is $M$-convergent to $m \circ s_0$.

Assuming axioms (P1), (P2), we are now in a position to prove a general theorem concerning the lower semi-continuity of integrals $\int f(\zeta, \varphi)$.

(5.1) Theorem. Consider a pair $(\zeta_0, \varphi_0)$ satisfying the following conditions:

1. There exists $\varphi > 0$ such that the set $\mathcal{R} = \{p : \|p - \cup \zeta_0(I)\| < \varphi\}$ has the property that $f(p, q) \geq 0$ for $p \in \mathcal{R}, q \in H$. Assume $D \supset N$
(2) At each point \((p_0, q_0) \in \mathcal{U} \zeta_0 (I), \|q_0\| = 1\), for given \(\varepsilon > 0\), there exists a \(q_0 > 0\), a weakly continuous linear functional \(\varpi_0 : H \to R\) (hence \(\varpi_0(h) = (h, a_0)\) for some \(a_0 \in H\)), and weak neighborhood \(W(p_0; z_1, \ldots, z_n; \varpi_0)\) of \(p_0\) such that for all \(p \in W(p_0; z_1, \ldots, z_n; \varpi_0)\) we have

(a) \(f(p, q) \geq \varpi_0(q)\) for every \(q \in H\);
(b) \(f(p, q) \leq \varpi_0(q) + \varepsilon/7M \|q\|\) for all \(q \in H\) such that \(q/\|q\| \in W^*(q_0; z_1^*, \ldots, z_n^*; \varpi_0)\), \(W^*\) a certain weak neighborhood of \(q_0\). Here \(M\) is a constant to be defined below.

(3) Condition \((f)\) is satisfied by \(f\), and \(\mathcal{F}((\zeta, \varphi), A)\) exists for each \((\zeta, \varphi) \in \mathcal{C}\).

(4) Each \((\zeta, \varphi) \in \mathcal{C}\) is such that condition \((\zeta)\) holds for the map \(\zeta\) while \(\varphi\) is of bounded variation.

(5) \(\mathcal{U} \zeta_0 (I)\) is a weakly compact subset of \(H\).

Then \(\int f(\zeta, \varphi)\) is lower semi-continuous at \((\zeta_0, \varphi_0)\) with respect to \(M\)-convergence.

**Proof.** Let \(\varepsilon > 0\) be given. Let \(M\) be a constant such that

\[ M \geq \sup \left\{ f(p, q) : (p, q) \in \mathcal{H} \times S^1, \|q\| \leq V(\|\varphi_0\|) \right\}. \]

From (2), for every point \(p_0 \in \mathcal{U} \zeta_0 (I)\) and \(q_0 \in S^1\), there exists \(q_0 > 0\), a weakly continuous linear functional \(\varpi_0(q) = (a_0, q)(q \in H)\), and weak neighborhoods \(W(p_0; z_1, \ldots, z_n; \varpi_0), W^*(q_0; z_1^*, \ldots, z_n^*; \varpi_0)\) of \(p_0, q_0\) respectively such that for all \(p \in W\) we have

(5.1) \[(a) f(p, q) \geq \varpi_0(q)\] for all \(q \in H\);
(b) \(f(p, q) \leq \varpi_0(q) \leq \varpi_0(q) + \varepsilon/7M \|q\|\) for all \(q \in H\) such that \(q/\|q\| \in W^*\).

Since \(S^1\) is weakly compact, invoking (5) we see that \(Y = \mathcal{U} \zeta_0 (I) \times S^1\) is compact in \(H \times H\). Hence \(Y\) may be covered by a finite number of the open sets

\[ W(p_0; z_1, \ldots, z_n; q_0) \times W^*(q_0; z_1^*, \ldots, z_n^*; q_0) \].

Let the centers of such a covering be \((p_i, q_i), i = 1, \ldots, r\), let the «radii» be \(\varrho_i\), let the associated functions be \(\varpi_i(q) = (a_i, q)\), and let the neighborhoods be

\[ W_i(p_i; z_1^i, \ldots, z_n^i; q_i), W_i^*(q_i; z_1^{i*}, \ldots, z_n^{i*}; q_i) \].

Now by assumption each \(\varpi_i\) is a weakly continuous linear functional on \(H\) and hence a fortiori is strongly continuous. We claim that \(\|\varpi_i\| = \|a_i\| \leq \varepsilon\). In fact, we find from (2) — (a) above that \(M \geq f(p_i, a_i/\|a_i\|) \geq \varpi_i(a_i/\|a_i\|) = \|a_i\|\) as desired. Let \(\varrho < \min\{\varepsilon/7M, \varrho_i, \varrho_i/\|z_j^i\|, \varrho_i/\|z_k^{i*}\| \} : \)
\[ i = 1, \ldots, r; j = 1, \ldots, n; k = 1, \ldots, m. \] With \( \sigma \) playing the role of \( \varepsilon \) in the definition of condition \( (\zeta_0) \), we may find a \( t'' \in T \) so that, among other things, \( t >> t'' \) yields \( (\varepsilon = \frac{\varepsilon}{t''}) \)

\[ (5.2) \quad \| z_0 \zeta_0 (J) - z_0 \zeta_0 (J) \| < \sigma \text{ for } c_0 \zeta_0 \in C_0, J \in C_i. \]

We chose \( \bar{t} \) such that \( \sigma \bar{t} >> \bar{t} \) implies

\[ (5.3) \quad | \mathcal{F}(\langle \zeta_0, \varphi_0 \rangle, A) - \sum_{l_x \in \mathcal{A}_0} f(\zeta_0, \varphi_0 (I_x)) | < \varepsilon/t. \]

Here \( \zeta_0 \) is an arbitrary element of \( C_0 \) which will remain fixed throughout the remainder of the proof. Now the point \( \langle \zeta_0, \varphi_0 (I_x), \varphi_0 (I_x) \rangle \) is in one of the sets of the cover above (if \( \| \varphi_0 (I_x) \| = 0, f(\zeta_0, \varphi_0 (I_x), \varphi_0 (I_x)) = 0 \) and thus will not effect our calculations). Denote this element of the cover by

\[ W_{r \xi}(I_x) (\mathcal{I}(I_x), \xi(I_x), \zeta_0 (I_x), \varphi_0 (I_x)) \times W_{r \xi}(I_x) (\mathcal{I}(I_x), \xi(I_x), \zeta_0 (I_x), \varphi_0 (I_x)), \]

or more simply by

\[ W_{r \xi}(I_x) (\mathcal{I}(I_x), \xi(I_x), \zeta_0 (I_x), \varphi_0 (I_x)). \]

Suppose the net \( (\alpha_n, \alpha \in (\mathcal{I}, \xi)) \) is \( M \)-convergent to \( s_0 \). In the definition \( (M_1) \) of \( M \)-convergence, let \( \sigma \) play the role of \( \varepsilon \), and take \( \sigma >> \sigma \). Hence there exists \( \zeta_0 \zeta_0 (I_x), \varphi_0 (I_x) \| \varphi_0 (I_x) \| \) in one of the sets of the cover above (if \( \| \varphi_0 (I_x) \| = 0, f(\zeta_0, \varphi_0 (I_x), \varphi_0 (I_x)) = 0 \) and thus will not effect our calculations). Denote this element of the cover by

\[ \mathcal{F}(\langle \zeta_0, \varphi_0 \rangle, A) - \sum_{l_x \in \mathcal{A}_0} f(\zeta_0, \varphi_0 (I_x)) | < \varepsilon/t. \]

\[ (5.4) \quad | (\varphi_0 (I_x) - \sum \varphi_0 (J), e_1) | < \varepsilon/t. \]
Observe that it may be assumed \( t_{I_0}^* \) so selected as to ensure in addition that if \( t_{I_0}^* \rightarrow_I a(I_0) t_{I_0}^* \), then

\[
(5.5) \quad |\mathcal{F}(\mathcal{C}_a, p_0), I_a| - \sum_{I_0} f(\overline{c}_0 \zeta(a)(J), p_a(J)) | < \epsilon/2N,
\]

\( \overline{c}_0 \) being a fixed choice function in \( C_a \). Here, in (5.4) and (5.5), \( \Sigma' \) denotes a sum over all \( J \in C_{I_0}^* \), \( \Sigma \) a sum over all \( J \in C_{I_0}^* \).

Next we note that for any \( e_0 \in C_0 \) and any \( I_a \in C_{I_0} \), we have, for arbitrary \( z_j(I_a) (j = 1, \ldots, n_{I_0}) \)

\[
|z_j^{(I_a)}(e_0, p_0)(I_a) - p_{I_0}I_a)|
\leq |z_j^{(I_a)}(e_0, p_0)(I_a) - \overline{c}_0 \zeta_0(I_a)| + |z_j^{(I_a)}(\overline{c}_0 \zeta_0(I_a) - p_{I_0}I_a)|
\leq \|z_j^{(I_a)}\| \epsilon + \theta(I_0) < 2 \theta(I_0)
\]

where we used relation (5.2) in passing from the second to the third line.

Similarly, for arbitrary \( e_0 \in C_a \),

\[
|z_j^{(I_a)}(e_0, p_0)(I_a) - p_{I_0}I_a)| \leq 2 \theta(I_0).
\]

Hence we may conclude \( \zeta_0(I_a) \in W_{II}(I_a) \), \( \zeta_0(I_a) \in W_{III}(I_a) \), for each \( I_a \in C_a \). Therefore, inequality (5.1)-(c) holds for all \( q \in H_0(I_a) \) or \( p \in \zeta_0(I_a) \), and (5.1)-(d) for \( \varphi_0(I_a) \). Then

\[
\mathcal{F}(\mathcal{C}_a, q_0), A) = \mathcal{F}(\mathcal{C}_a, p_0), A) = \\
= [\mathcal{F}(\mathcal{C}_a, q_0), A] - \sum_{I_a \in C_a} \mathcal{F}(\mathcal{C}_a, q_0), I_a] \\
+ \sum_{I_a \in C_a} [\mathcal{F}(\mathcal{C}_a, q_0), I_a] - \sum_{I_a \in C_a} f(\overline{c}_0 \zeta_0(J), q_a(J)) \\
+ \sum_{I_a \in C_a} \sum_{a_0(I_a), q_a(J)} f(\overline{c}_0 \zeta_0(I_a), q_a(J)) - \zeta_0(I_a), q_a(J)) \\
+ \sum_{I_a \in C_a} [a_0(I_a), \zeta_0(I_a) - q_0(I_a)] \\
+ \sum_{I_a \in C_a} [a_0(I_a), \zeta_0(I_a) - f(\overline{c}_0 \zeta_0(I_a), q_0(I_a))] \\
+ \sum_{I_a \in C_a} f(\overline{c}_0 \zeta_0(I_a), q_0(I_a)) - \mathcal{F}(\mathcal{C}_a, p_0), A)] \\
= a_1 + a_2 + a_3 + a_4 + a_5 + a_6 + a_7.
We shall now examine the sums $\sigma_i (i = 1, \ldots, 7)$. It follows from axiom $(P_2)$ that $\sigma_1 \geq 0$. Relation (5.5) implies $|\sigma_2| < \epsilon/7$. Since

$$\sup_{\mathcal{F} \in \mathcal{I}} \left\| c_0 \xi_0 (I_0) - c_0 \xi_0 (J) \right\| < \epsilon \quad \text{for } \mathcal{F} \in \mathcal{C}_a$$

since $C_{I_0} \subset C_{I_0}$, and since $f(p, q) \geq 0$ for $p \in \mathcal{H} = \{ p : \left\| p - U \xi_0 (I) \right\| < \epsilon \}$, $q \in H$, we see that $f(c_0 \xi_0(J), \varphi_0(J)) \geq 0$ and hence $\sigma_3 \geq 0$. Next, given $I_0 \in C_{I_0}$ and $J \subset I_0$, an argument used before shows that

$$|z_{j(I_0)}(c_0 \xi_0(J)) - p_{i(I_0)}| \leq 3 q_{i(I_0)}.$$

Thus, in virtue of (5.1)-(a), $\sigma_4 \geq 0$. To discuss $\sigma_5$, observe that our isometry $m_{(L_0)}$ may be chosen so that $a_{i(L_0)} / |a_{i(L_0)}| = m_{i(L_0)}^* e_1, m_{i(L_0)}^*$ denoting the adjoint of $m_{i(L_0)}$. Hence

$$|a_{i(L_0)} \Sigma \varphi_0 (J) - \varphi_0 (I_0)| \leq$$

$$\leq \| a_{i(L_0)} \| \| m_{i(L_0)}^* e_1, \Sigma \varphi_0 (J) - \varphi_0 (I_0) \|$$

$$\leq \| a_{i(L_0)} \| \| (e_1, m_{i(L_0)} (\Sigma \varphi_0 (J) - \varphi_0 (I_0)) \|$$

$$\leq \| a_{i(L_0)} \| \| (e_1, (\Sigma \varphi_0 (J) - \varphi_0 (I_0)) \|$$

$$< \epsilon/7 MN \| a_{i(L_0)} \| \quad \text{(by relation (5.4).)}$$

Consequently

$$|\sigma_5| < \epsilon/7 MN \Sigma_{I_0 \subset C_{I_0}} \| a_{i(L_0)} \| \leq \epsilon/7 MN MN = \epsilon/7,$$

where we recalled $\| a_{i(L_0)} \| = |w_{i(L_0)}| \leq M$.

From (5.1)-(b) we deduce

$$f(c_0 \xi_0 (I_0), \varphi_0 (I_0)) \leq (a_{i(L_0)}, \varphi_0 (I_0)) + \epsilon/7 M \| \varphi_0 (I_0) \|.$$ 

Therefore

$$\sigma_6 \geq \Sigma_{I_0 \subset C_{I_0}} e/7 M \| \varphi_0 (I) \| \geq \epsilon/7 M (\Sigma - V) \geq - \epsilon/7.$$

Relation (5.3) implies $|\sigma_7| < \epsilon/7$. 

Thus we see that
\[
\mathcal{J}(\zeta_x, \varphi_x, A) - \mathcal{J}(\zeta_0, \varphi_0, A) > -4\varepsilon/7 > -\varepsilon
\]
for all \(x \geq x_0\), and from this it follows that \(I\) is lower-semicontinuous at \((\zeta_0, \varphi_0)\) with respect to \(M\)-convergence. This completes the proof.

We shall refer to condition (1) in (5.1) by saying that \(f\) is "non-negative near \(s_0\)" and condition (2) by saying that \(f\) is "\(s_0\)-convex."

We now give two illustrations of the preceding theorem.

**Example 1.** Let the set \(A\) be a finite closed interval, say \([0, 1]\), of the line; let \(I\) be the class of all intervals \(I = [a, b] \subset A\), and \(T = \mathcal{T}\) the class of all finite subdivisions \(t = D = \{I_j: j = 1, \ldots, N\}\) of \([0, 1]\]. Consider the collection \(\mathcal{O} = \mathcal{O}(L)\) of all continuous parametric rectifiable curves \(C: x = x(w), 0 \leq w \leq 1, x = (x_1, \ldots, x_k)\) with range in some set \(L \subset E^k\). Then with each such \(x\) we may associate an interval function \(\zeta_x(I) = \zeta(I) = \bigcup_{w \in I} x(w)\). Each \(\zeta_x\) satisfies condition (\(\zeta_x\)). Moreover put \(\varphi_x(I) = \varphi(I) = (\varphi_1, \ldots, \varphi_k), \varphi_r(I) = x_r(b) - x_r(a)\), \(r = 1, \ldots, k\), for every \(I = [a, b] \subset A\).

Our collection \(\mathcal{S}\) will then be the collection of all pairs \((\zeta_x, \varphi_x)\). Given a pair \((\zeta_x, \varphi_x)\), the set \(T = \mathcal{T}\) is directed by the mesh function \(\delta_x(D) = h_x(D) = \max_{I \in D} h_I, \max (\text{oscillation of } x \text{ on } I), \text{ if we require that } I \cap D = \emptyset\). Given a sequence \(x_n\) of continuous parametric rectifiable curves which converge uniformly to a continuous parametric rectifiable curve \(x_0\), that is, \(\sup_{w \in A} |x_n(w) - x_0(w)| \to 0\) as \(n \to \infty\). Then we claim that the sequence \((\zeta_{x_n}, \varphi_{x_n})\) is \(M\)-convergent to \((\zeta_0, \varphi_0)\). In fact, let \(\varepsilon > 0\) and \(I = [a, b] \subset A\) be given. Let us first verify (\(M_1\)) - (a). Evidently, for this purpose, it suffices to show that there exists an integer \(N_0\) and a system \(t_n \in D_{\ast\ast}\) such that for all \(n \geq N_0\) we have \(\delta_n(D_{\ast\ast}) < \varepsilon\) and \(\delta_n(D_{\ast\ast\ast}) < \varepsilon\). Since \(x_n\) converges uniformly to \(x_0\), these functions \((x_n, n = 0, 1, \ldots)\) are equicontinuous and so there is a rational number of the form \(r^{-1} < \varepsilon/4\) such that \(||x_n(w') - x_n(w'')|| < \varepsilon/4\) if \(||w' - w''|| < q^{-1}\).

Subdivide \([0, 1]\) into \(q\) equal parts, and let \(t_{\ast\ast} = D_{\ast\ast}\) denote the subdivision so obtained. Notice that for all \(n\), \(h_n(D_{\ast\ast\ast}) < \varepsilon/4\). Choose \(N_0\) such that \(n \geq N_0\) implies \(||x_n(w) - x_0(w)|| < \varepsilon/4\) for all \(w \in [0, 1]\). We then have

(a) \(\delta_n(D_{\ast\ast\ast}) = \max |I_j| + h_n(D_{\ast\ast\ast}) < \varepsilon/4 + \varepsilon/4 < \varepsilon\) for all \(n = 0, 1, 2, \ldots\).
We consider where Thus

The fact that sup is clear. Hence $(M_1)$ is verified.

Next, we check condition $(M_2)$. In order to do this we first have to specify, for each $I \in \{I\}$ in accordance with $(P_1)$, the set $T_I$ and intervals $(J) \subset I$.

So, if $I = [a, b] \subset [0, 1]$, we let $T_I$ be the set of all finite subdivisions of $[a, b]$ and $(J) = [c, d] : [c, d] \subset I$.

We can then define, in an analogous way to the case $A = (0, 1)$, the mesh functions $\delta_I$ and the orderings of $T_I$. Having done this, we now observe, since one interval is as good as the next, that it is sufficient to check for $I = [0, 1]$ only. But, noticing that for any subdivision $D = (h : j = 1, \ldots, N)$ of $[0, 1]$ whatsoever we have in general $\|f_0(I) - x_0(w')\| + \|x_0(w') - x_0(w'')\| < \varepsilon$.

Hence we may conclude: Uniform convergence of $x_n$ to $x_0$ implies $M$-convergence of $\zeta_n(0, \varphi_0)$. Moreover, since uniform convergence is preserved under isometries $m$, we infer that $(m\zeta_n, m\varphi_0)$ is $M$-convergent to $(\zeta_0, \varphi_0)$.

Now let $f : L \times E^k \rightarrow R$ be a parametric integrand satisfying the usual hypotheses of continuity (that is, condition $(f)$). For each $I \in \{I\}$, and pair $(\zeta, \varphi) \in \bar{G}_I$, it is evident that $(f, I) \int f(\zeta, \varphi)$ is meaningful (each $\varphi$ is quasi-additive, see [5, p. 103]) and conditions $(P_1)$, $(P_2)$ above are satisfied. The integral which arises here then is nothing more than the classical Weierstrass integral over a rectifiable continuous curve. Observe that $\cup \zeta_0(I) = \text{range } x_0$ is a compact subset of $E^k$. Thus, if the conditions (1), (2) of Theorem (5.1) on $f$ are satisfied, we are able to state a semi-continuity theorem in the calculus of variations due to Tonelli.

Theorem (Tonelli). Let $f : L \times E^k \rightarrow R$ satisfy condition $(f)$. Let $\Omega$ be the class of all continuous rectifiable parametric curves $x : [0, 1] \rightarrow L \subset E^k$.

If $x_0 \in \Omega$ is such that $f$ is non-negative near $s_0 = (\zeta_0, \varphi_0)$ and is $s_0$-convex, then the integral $\int f(x_0, \varphi, A)$ is lower semi-continuous at $x_0$ in $\Omega$ with the uniform topology.

**Example 2.** We wish to deduce here a theorem proved by Turner [9, p. 112] on the semi-continuity of the Cesari-Weierstrass surface integral. The reader is referred to [12, Section 5] for the notations and definitions to be employed here. Let the admissible set $A$ be the square. Let
be the class of all closed simple polygonal regions $I \subset A$, and $T = \mathcal{H}$ the class of all finite systems $D = [I] = [I_1, \ldots, I_N]$ of non-overlapping regions $I \in \mathcal{H}$. Let $\mathcal{S} = \mathcal{S}(L)$ be the class of all continuous $BV$ mappings $x : A \to L \subset E^3$ (in other words, continuous surfaces $S$ in $L$ with finite Lebesgue area). Then with each such $x$ we may associate an interval function $\zeta(I) = \zeta_x(I) = \bigcup \{x(w)\}$. Moreover, we put

\[
\varphi(I) = \varphi_x(I) = (\varphi_1(I), \varphi_2(I), \varphi_3(I)), \quad \varphi_v(I) = v(x_r, I), \quad r = 1, 2, 3
\]

where $v(x_r, I)$ is the relative variation (signed area) of the plane mapping $(x_r, I)$. It is known that $\varphi$ is quasi-additive with respect to $\mathcal{G}$ and $\delta(D)$ [12, Section 5]. Our collection $\mathcal{S}$ will then be the collection of all pairs $(x, I)$. The set $T = \mathcal{H}$ is directed in the usual fashion for $S_2$-type systems. Given $x$, an orthogonal transformation $m : E^2 \to E^3$ determines a new map $m x$ and corresponding $\zeta_{mx}$ in the obvious way. The fact that $\varphi_{mx} = m \varphi_x$ is well-known [4]; hence condition $(m)$ is satisfied by the collection $\mathcal{S}$. Suppose $\{x_n\}$ is a sequence of continuous parametric surfaces of finite Lebesgue area which converge uniformly to a continuous parametric surface $x_0$ of finite Lebesgue area, that is $\sup_{w \in A} \|x_n(w) - x_0(w)\| \to 0$. Then we claim that the sequence $\{\zeta_n, \varphi_n\}$ is $\mathcal{H}$-convergent to $(\zeta_0, \varphi_0)$. Let us first verify $(M_1)(a)$. It suffices to show that there exists an integer $N_0$ and a system $i \in \mathcal{H}_i$ such that for all $n \geq N_0$ we have $\delta_n(D \ast n) < \varepsilon$ and $\delta_0(D \ast n) < \varepsilon$. This fact, however, is a consequence of a lemma proved by L. Cesari [1, p. 1385]. Likewise, $(M_2)$ holds. It remains to verify $(M_3)$. In order to do this, we first have to specify for each $I \in \mathcal{H}$, in accordance with $(P_1)$, the set $T_I$ and intervals $\{J_i \subset I\}$. So, given $I \in \mathcal{H}$, we take for $T_I$ the set of all simple closed polygonal regions $J$ such that $J \subset I$. We can then define the mesh functions $\delta_I$ and the orderings $\gg_I$ of $T_I$ in the usual way. Let $\varepsilon > 0$ be given along with $I \in \mathcal{H}$. Let $\{e_1, e_2, e_3\}$ be the usual orthonormal basis of Euclidean space $E_3$. Then $(\varphi_0, e_1) = \varphi_{01}$, where $\varphi_{01}$ is the signed area function of the plane mapping $r_1 x_0 = x_{01} : A \to E^2$, $r_1$ denoting the projection of $E^3$ onto the $y z$ plane. According to a lemma to be found in [11, p. 198], there is a number $\nu > 0$ with the following property:

For every continuous $BV$ plane mapping $y : A \to E^2$ with $\|y(w) - x_{01}(w)\| < \nu$ for all $w \in A$, there is an $\eta = \eta(\varepsilon, \nu) > 0$ such that every finite system $D \subset \mathcal{H}$ with $\delta_D(D) < \eta$ has a subsystem $D' \subset D$ satisfying

\[
|\varphi_{01}(A) - \Sigma_{D'} \varphi_{01}(J)| < \varepsilon
\]

where $\Sigma_{D'}$ denotes a sum over all $J \in D'$. The lemma is equally applicable if we take $A = I$, $I \in \mathcal{H}$. 

Hence choose $N_0$ so that $\sup_{n \geq N_0} \| x_n (w) - x_0 (w) \| < \nu I$ for all $n \geq N_0$
(thus $N_0$ plays the role of $a^g$ in condition (M2)). Then take any $n \geq N_0$;
certainly $\sup_{w \in A} \| x_n (w) - x_0 (w) \| < \nu I$, and thus
\[
\| x_n (w) - x_0 (w) \| = \| r_1 x_n (w) - r_1 x_0 (w) \|
\leq \| x_n (w) - x_0 (w) \| < \nu I
\]
on I too. Hence there exists $\eta_I = \eta_I (\epsilon, x_n) > 0$ such that every $t^s_{I} = D^s_{I}$
with $\delta_{x_n} (D^s_{I}) < \eta_I$ has a subsystem $D^s_{I} < D^s_{I}$ satisfying $| \varphi_{01} (I) - \Sigma' \varphi_{01} (J) | < \epsilon$
that is, $| (\varphi_{01} (I) - \Sigma' \varphi_{01} (J)) | < \epsilon$ where $\Sigma'$ denotes a sum over all $J \in D^s_{I}$.
So select $t^s_{I} = D^s_{I}$ with $\delta_{x_n} (D^s_{I}) < \eta_I$. If $t^s_{I} = D^s_{I} >> (\varphi_{01}) t^s_{I} = D^I_{I}$, that is,
if $\delta_{x_n} (D^s_{I}) \leq \delta_{x_n} (D^I_{I}) < \eta_I$, then $\delta_{x_n} (D^s_{I}) \leq \delta_{x_n} (D^I_{I}) < \eta_I$ from a known
property of the mesh $\delta$ (see [4, p. 331]). Therefore condition (M2) follows.
We conclude: Uniform convergence of to $x, \nu$ implies $\nu$ convergence of
$\nu$ to $(1, \nu, \varphi_{01})$. Since uniform convergence is preserved under isometries
$m$, we infer that $\nu m_{\varphi_{01}} = \nu m_{\varphi_{01}}$ is $\nu$-convergent to $(m_{\varphi_{01}}, \nu m_{\varphi_{01}})$.

Let $f : L \times E^3 \to R$ be a parametric integrand with the usual pro-
perties. The conditions $(P_1)$, $(P_2)$ above are satisfied here, the integral $(I)$
$\int f (\zeta, \varphi)$ being the Cesari-Weierstrass integral over a continuous $BV$ surface.
Finally, $U \zeta_0 (I) = \text{range } x_0$ is a compact subset of $E^3$. We can now deduce
from Theorem (5.i) the Turner theorem.

Theorem (Turner). Let $f : L \times E^3 \to R$ satisfy condition $(f)$. Let
$\Omega = \Omega (L)$ be the class of all continuous surfaces of finite Lebesgue area
$x : A \to L \subset E^3$. If $x_0 \in \Omega$ is such that $f$ is non negative near $s_0 = (\zeta_0, \varphi_0)$
and is $s_0$ convex, then the integral $\mathcal{I} (\zeta_0, \varphi) (A)$ is lower semi-continuous at
$x_0$ in $\Omega$ with the uniform topology.
