A REMARK ON HARMONIC ANALYSIS OF STRONGLY ALMOST-PERIODIC GROUPS OF LINEAR OPERATORS

S. ZAIDMAN ⁽¹⁾

1. Introduction.

Let us consider a Banach space \mathcal{X} , and then take a one parameter group of linear operators $G(t)$, $-\infty < t < \infty \rightarrow \mathcal{L}(\mathcal{X}, \mathcal{X})$, which is strongly almost-periodic; this means that for any $x \in \mathcal{X}$, the \mathcal{X} -valued function $y(t) = G(t)x$ is (Bochner)-almost-periodic (see [2]).

It is a well-known result (see for example [1]), that for any \mathcal{X} -valued almost-periodic function $f(t)$, the mean value

$$(1.1) \quad \mathcal{M}(e^{-i\lambda t} f(t)) = \lim_{T \rightarrow \infty} \frac{1}{2T} \int_{-T}^T e^{-i\lambda \sigma} f(\sigma) d\sigma$$

exists for any real number λ .

Furthermore, this mean-value equals θ for all λ with the possible exception of a set $(\lambda_n)_{n=1}^{\infty}$ which is finite or countable, and is denoted by $\sigma(f)$.

A natural problem is the following ⁽²⁾:

Is there any strongly almost-periodic one-parameter group $G(t)$, with the property that

$$(1.2) \quad \bigcup_{x \in \mathcal{X}} \sigma(G(t)x) = \text{real line?}$$

Answering to a letter of us, professor S. Bochner indicated a solution; this will be explained here with some more details.

Pervenuto alla Redazione il 28 Luglio 1971.

⁽¹⁾ This research is supported by a grant of the National Research Council of Canada.

⁽²⁾ It arose in connection with our paper [3].

2. We shall remember here the definition of the space $l^2[-\infty, \infty]$.

It consists of all complex-valued functions $a(\lambda)$, defined for $-\infty < \lambda < \infty$, having the property that

$$(2.1) \quad \sum_{-\infty < \lambda < \infty} |a(\lambda)|^2 < \infty$$

In fact, (2.1) means, by definition, that for a certain constant $c > 0$ we have

$$(2.2) \quad \sum_{i=1}^n |a(\lambda_i)|^2 < c$$

whenever arbitrary real λ_j are chosen (and for any $n = 1, 2, 3, \dots$).

Let us remark that if $a(\lambda) \in l^2[-\infty, \infty]$ there exists a sequence $(\lambda_n)_{n=1}^{\infty}$ depending on $a(\lambda)$, such that $a(\lambda) = 0$ if $\lambda \neq \lambda_j$, $\forall j = 1, 2, \dots$

This follows because, if we put $\mathcal{E}_j = \left\{ \lambda \in \mathbb{R}^1, |a(\lambda)| > \frac{1}{j} \right\}$ we see that every \mathcal{E}_j is a finite set; hence $\bigcup_{j=1}^{\infty} \mathcal{E}_j = \mathcal{E}$ is a countable set, and if $a(\lambda) \neq 0$ then $\lambda \in \mathcal{E}$.

Let us denote the set $\{\lambda; a(\lambda) \neq 0\}$ by $Sp a(\cdot)$; so $Sp a(\cdot) \subset \mathcal{E}$ is a finite or countable set, $(\lambda_n)_{n=1}^{\infty}$, and we take a fixed ordering of it.

It can be proved that $l^2[-\infty, \infty]$ is a linear space on the complex field. We can introduce a scalar product on this space; if $a(\lambda), b(\lambda) \in l^2[-\infty, \infty]$, and $(\lambda_n)_{n=1}^{\infty} = Sp a(\cdot)$, $(\mu_n)_{n=1}^{\infty} = Sp b(\cdot)$, then by definition $(a(\lambda), b(\lambda))_{l^2[-\infty, \infty]} = \sum_{j=1}^{\infty} a(\lambda_j) \bar{b}(\mu_j)$; this sum becomes finite if one of $Sp a(\cdot)$ or $Sp b(\cdot)$ is finite.

It can be proved in the usual manner that $l^2[-\infty, \infty]$ is a (complete) Hilbert space.

Let us consider now, for any real number t , the map of $l^2[-\infty, \infty]$ into itself which is defined by

$$(2.3) \quad a(\lambda) \rightarrow e^{it\lambda} a(\lambda)$$

We shall denote this map by G_t ; we see that $G_{t_1+t_2} = G_{t_1} G_{t_2}$, $G_0 = I$ for any pair t_1, t_2 of real numbers; here I is the identity operator in l^2 .

Furthermore, if $(\lambda_n)_{n=1}^{\infty} = Sp a(\cdot)$, we have

$$(2.4) \quad \|G_t a(\cdot)\|_{l^2}^2 = \sum_{j=1}^{\infty} |e^{it\lambda_n} a(\lambda_n)|^2 = \sum_{j=1}^{\infty} |a(\lambda_n)|^2 = \|a(\cdot)\|_{l^2}^2$$

so G_t is an isometric map of l^2 , \forall real t .

3. In this part of the paper we prove the following

THEOREM. *The one-parameter group G_t is strongly almost periodic in l^2*

We need for the proof several Lemmas.

Consider, for a given $\lambda_0 \in (-\infty, \infty)$, the function $\varphi_{\lambda_0}(\lambda)$ which equals 1 for $\lambda = \lambda_0$, and equals 0 for $\lambda \neq \lambda_0$. Obviously $\varphi_{\lambda_0}(\lambda) \in l^2$, and $Sp \varphi(\cdot) = \{\lambda_0\}$. Now, we have

LEMMA 1. *Let $a(\lambda)$ be given in l^2 , and $(\lambda_n)_1^\infty = Sp a(\cdot)$. Then we have*

$$(3.1) \quad a(\lambda) = \sum_{j=1}^{\infty} a(\lambda_j) \varphi_{\lambda_j}(\lambda), \text{ the convergence being in } l^2[-\infty, \infty]$$

Let us put in fact $b_N(\lambda) = a(\lambda) - \sum_{n=1}^N a(\lambda_n) \varphi_{\lambda_n}(\lambda)$.

It can be seen without difficulty that $Sp b_N(\cdot) = (\lambda_{N+1}, \lambda_{N+2}, \dots)$. Hence

$$\|b_N(\lambda)\|_{l^2}^2 = \sum_{j=1}^{\infty} |b_N(\lambda_{N+j})|^2; \text{ but } b_N(\lambda_{N+j}) = a(\lambda_{N+j}); \text{ hence}$$

$$\sum_{j=1}^{\infty} |b_N(\lambda_{N+j})|^2 = \sum_{j=1}^{\infty} |a(\lambda_{N+j})|^2 = \sum_{k=N+1}^{\infty} |a(\lambda_k)|^2$$

This last expression tends to 0 as $N \rightarrow \infty$, because $a(\lambda) \in l^2$. This proves Lemma.

Then we remark the trivial fact that

$$(3.2) \quad Sp(e^{it\lambda} a(\lambda)) = Sp(a(\lambda)) \text{ for any real } t.$$

Applying Lemma 1 we obtain that for any real t we have

$$(3.3) \quad e^{it\lambda} a(\lambda) = \sum_{n=1}^{\infty} e^{it\lambda_n} a(\lambda_n) \varphi_{\lambda_n}(\lambda)$$

the convergence being in $l^2[-\infty, \infty]$.

Also we have the simple

LEMMA 2. *Any function $-\infty < t < \infty \rightarrow l^2[-\infty, \infty]$ which is given by*

$$(3.4) \quad h_n(t) = e^{it\lambda_n} a(\lambda_n) \varphi_{\lambda_n}(\cdot) \text{ is } l^2\text{-almost-periodic.}$$

This is a particular case of the fact that if \mathcal{X} is a Banach space, $x \in \mathcal{X}$, and α is a real number, the function $-\infty < t < \infty \rightarrow \mathcal{X}$, given by $e^{iat} x$

is \mathcal{X} almost-periodic (in fact it is \mathcal{K} -periodic). In our case $\alpha = \lambda_n$, $x = a(\lambda_n) \varphi_{\lambda_n}(\lambda)$, $\mathcal{X} = l^2$.

It follows from (3.3) that $e^{it\lambda} a(\lambda)$ is l^2 -almost-periodic, if we prove that the convergence in (3.3) is uniform with respect to $t \in (-\infty, \infty)$. This is done in

LEMMA 3. *The series $\sum_{n=1}^{\infty} e^{i\lambda_n} a(\lambda_n) \varphi_{\lambda_n}(\lambda)$ is convergent to $e^{it\lambda} a(\lambda)$ in l^2 -norm, uniformly for $-\infty < t < \infty$.*

Let us consider in fact the difference

$$(3.5) \quad g_N(\lambda, t) = e^{it\lambda} a(\lambda) - \sum_{n=1}^N e^{i\lambda_n} a(\lambda_n) \varphi_{\lambda_n}(\lambda).$$

We see that

$$g_N(\lambda, t) = 0 \text{ if } \lambda \notin Sp a(\cdot) \text{ or if } \lambda \in [\lambda_1, \lambda_2, \dots, \lambda_N];$$

moreover

$$g_N(\lambda, t) = e^{i\lambda_{N+j}} a(\lambda_{N+j}) \text{ for } \lambda \in [\lambda_{N+1}, \lambda_{N+2}, \dots].$$

Consequently $Sp g_N(\cdot, t) = (\lambda_{N+1}, \lambda_{N+2}, \dots)$ and

$$(3.6) \quad \|g_N(\lambda, t)\|_{l^2}^2 = \sum_{j=1}^{\infty} |e^{i\lambda_{N+j}} a(\lambda_{N+j})|^2 = \sum_{k=N+1}^{\infty} |a(\lambda_k)|^2$$

which tends to 0 as $N \rightarrow \infty$, obviously uniformly with respect to $t \in (-\infty, \infty)$. This proves the Theorem.

Let us consider $a(\lambda) = \varphi_{\lambda_0}(\lambda)$ for any fixed $\lambda_0 \in (-\infty, \infty)$.

Then

$$G_t \varphi_{\lambda_0}(\lambda) = e^{it\lambda} \varphi_{\lambda_0}(\lambda) = e^{i\lambda_0 t} \varphi_{\lambda_0}(\lambda) \text{ as easily seen.}$$

This is a l^2 -valued periodic function and $\sigma(e^{i\lambda_0 t} \varphi_{\lambda_0}(\cdot)) = \{\lambda_0\}$. Hence $\bigcup_{\lambda_0 \in \mathbb{R}^1} \sigma(G_t \varphi_{\lambda_0}(\cdot)) = \text{real line } \mathbb{R}^1$ and this solves the problem in the Introduction.
