RIGID ANALYTIC SPACES (*)

by Marius VAN DER PUT

1. Tate-algebras.

(1.1) Notations. - $k$ is a complete non-archimedean valued field. For a Banach-algebra $A$ over $k$ (always commutative and with 1) and indeterminates $T_1, \ldots, T_n$, we define

$$A(T_1, \ldots, T_n) = \{ \sum a_\alpha T^\alpha ; a_\alpha \in A \text{ and } \lim a_\alpha = 0 \}.$$ 

This is a new Banach-algebra over $k$ with respect to (w.r.t.) the norm $\|\sum a_\alpha T^\alpha\| = \max|a_\alpha|$. A free Tate-algebra is a ring of the type $k(T_1, \ldots, T_n)$.

(1.2) PROPOSITION (Weierstrass preparation and division). - Let $f \in k(T_1, \ldots, T_n)$ be non-zero. There exists an automorphism $\sigma$ of $k(T_1, \ldots, T_n)$ (of the form $X_i \mapsto X_i + X_i^{e_i}$, $e_i > 1$, $i < n$; $X_n \mapsto X_n$) such that $\sigma(f)(0, -\ldots, T_n)$ has order $d$.

Moreover $k(T_1, \ldots, T_n)/\sigma(f)$ is a free finitely generated $k(T_1, \ldots, T_{n-1})$-module of rank $d$.

Proof. - See [7] GRAUERT-REMMERT.

(1.3) Consequences.

(1.3.1) Every $k(T_1, \ldots, T_n)$ is noetherian.

(1.3.2) $k(T_1, \ldots, T_n)$ is a unique factorisation domain.

Proof. - Induction on $n$ and (1.2).

(1.4) LEMMA. - Let $M$ be a Banach-module over $A$ (i.e. $A$ Banach-algebra and $M$ is a complete normed $A$-module s.t. $\|am\| \leq \|a\| \cdot \|m\|$, $\forall a \in A$, $\forall m \in M$).

The following are equivalent

(a) $M$ is noetherian.

(b) Every $A$-submodule of $M$ is closed.

(*). Survey of the works done by J. TATE, H. GRAUERT, R. REMMERT, L. GERRITZEN, R. KIEHL, L. GRUSON, M. RAYNAUD and al.
Proof. - (b) ⇒ (a): Let $M_1 \subsetneq M_2 \subsetneq M_3 \subsetneq \ldots$ be an infinite chain of submodules of $A$. Then one can easily see that $\bigcup_{i \geq 1} M_i$ is not closed. Contradiction.

(a) ⇒ (b): Let $N$ be a maximal non-closed submodule of $M$. Then $N \subsetneq \overline{N}$ has no intermediate $A$-modules. Hence $\overline{N}/N \cong A/\mathfrak{m}$ for some maximal ideal $\mathfrak{m}$. Since $\mathfrak{m}$ is closed in $A$ it follows that $N$ is also closed. Contradiction.

(1.5) Every ideal $I$ in $k\langle T_1, \ldots, T_n \rangle$ is closed according to (1.4) and (1.3.1). A Tate-algebra is an algebra of the type $k\langle T_1, \ldots, T_n \rangle/I$ provided with the quotient norm.

Easy consequences are:

(1.5.1) Any $k$-homomorphism of Tate-algebra is continuous.

(1.5.2) Any finitely generated module over a Tate-algebra $A$ has a unique structure as Banach-module. A linear map between those modules is automatically continuous.

(1.6) From (1.2), it follows:

For every Tate-algebra $A$, there exists a map $K\langle T_1, \ldots, T_d \rangle \rightarrow A$ with $\alpha$ injective and finite. Moreover $d = \text{Krull-dim } A$.

In particular, for every maximal ideal $\mathfrak{m}$ of $A$, we have $[(A/\mathfrak{m}) : k] < \infty$. On $A/\mathfrak{m}$, we put the unique valuation extending the valuation of $k$.

(1.7) Some notations.

$X = \text{Sp } A = \text{the set of maximal ideals of } A$.

For $x \in X$, we put $k(x) = A/x$. For $f \in A$, we denote by $f(x)$ the image of $f$ into $A/x$. The spectral semi-norm $\|f\|_{\text{sp}}$ is defined by $\|f\|_{\text{sp}} = \sup_{x \in X} |f(x)|$.

For $A = k\langle T_1, \ldots, T_n \rangle$ one easily checks $\|f\|_{\text{sp}} = || ||$ and the norm is multiplicative.

(1.8) Properties of the spectral norm.

(1.8.1) $|f(x)| < \text{ for all } x \in X \iff \lim ||f^n|| = 0$.

(1.8.2) $\|f\|_{\text{sp}} = \lim ||f^n||^{1/n}$.

(1.8.3) $|f(x)| \leq 1$ for all $x \in X \iff \sup_n ||f^n||; n \geq 0 < \infty$.

(1.8.4) A $k$-algebra homomorphism $\varphi : A\langle T_1, \ldots, T_n \rangle \rightarrow B$ is uniquely determined by $\varphi/A$ and $\varphi(T_i) = f_i \in B$ $(i = 1, \ldots, n)$. $A \rightarrow \varphi$ with prescribed $\varphi/A$ and $f_i$ $(1 \leq i \leq n)$ exists if, and only if, $|f_i(x)| \leq 1$ for all $x \in \text{Sp}(B)$ and $i = 1, \ldots, n$.

(1.8.5) If $A$ is reduced (i.e. has no nilpotents elements) then $\| ||$ is equivalent with $|| ||$. 

There is \( x_0 \in X = \text{Sp} A \) with \( |f(x_0)| = \max_{x \in X} |f(x)| \).

**Proof.** (1.8.1): The ideal \((1 - Tf) A(I)\) in \( A(I)\) must be improper because of (1.6) and \( |f(x)| < 1 \) for all \( x \in X \). Hence \((1 - Tf)\) has an inverse in \( A(I)\). That inverse must be \( \sum_{n \geq 0} f^n t^n \). So \( \lim \|f^n\| = 0 \).

On the other hand, if \( \lim \|f^n\| = 0 \), then \( |f(x)| \leq \|f^n\|^{1/n} \) is < 1 for all \( x \) and \( n \gg 0 \).

(1.8.2): "\( \leq \)" is trivial. If \( \|f\|_{\text{sp}} < \lim \|f^n\|^{1/n} \), then we can arrange things such that \( \|f\|_{\text{sp}} \leq 1 \leq \lim \|f^n\|^{1/n} \). But this contradicts (1.8.1).

(1.8.3): The implication "\( \implies \)" follows from (1.8.2). The implication "\( \implies \)" is more complicated:

Suppose that \( k(\bar{T}_1, \ldots, \bar{T}_d) \hookrightarrow A \) is injective and finite. If we can show that \( f \in A \) is integral over \( V(\bar{T}_1, \ldots, \bar{T}_d) \) \( (V \) the valuation-ring of \( k \) \), then clearly \( \{|f^n|/n \geq 0\} \) is a bounded set. For show the integral dependence of \( A \), it suffices to consider the case where \( A \) has no zero-divisors.

Let \( L \) be the least normal field extension of \( K = \mathcal{Q}(k(\bar{T}_1, \ldots, \bar{T}_d)) \) containing \( A \), and let \( G = \text{Aut}(L/K) \). Then \( B = \mathcal{Z}(A^G; \sigma \in G) \) is also integral over \( k(\bar{T}_1, \ldots, \bar{T}_d) \) and the minimum polynomial of \( f \) over \( K \) divides

\[ P = \prod_{\sigma \in G}(X - f^\sigma)^q \quad (q \text{ is some power of the characteristic}). \]

Since \( k(\bar{T}_1, \ldots, \bar{T}_d) \) is normal, \( P \) has coefficients in \( k(\bar{T}_1, \ldots, \bar{T}_d) \). Since \( |f^\sigma(x)| \leq 1 \) for all maximal ideal of \( B \), the coefficients of \( P \) have spectral norms \( \leq 1 \). So \( P \in V(\bar{T}_1 \ldots \bar{T}_d)[X] \).

(1.8.4): Easy consequence of (1.8.3).

(1.8.5): This is more complicated (proved by L. GERRITZEN). We only sketch a proof. As in (1.8.3), we may suppose that \( A \) has no zero-divisors. Let \( f \in A \) have minimum polynomial \( X^d + a_1 X^{d-1} + \ldots + a_d = 0 \) over \( k(\bar{T}_1, \ldots, \bar{T}_d) \). Then \( \|f\|_{\text{sp}} = \max_{1 \leq i \leq s} \|a_i\|^{1/i} \). The hard part is to show with the aid of this formula that \( A \) is complete w. r. t. \( \| \|_{\text{sp}} \). Then it follows from the open mapping theorem that \( \| \|_{\text{sp}} \) and \( \| \| \) are equivalent on \( A \) (See R. REMMERT [14]).

(1.8.6): By the formula of (1.8.5) one sees that, after replacing \( f \) by \( \lambda f^e \) \( (e \geq 1, \lambda \in k^\times) \), we may work with \( \|f\|_{\text{sp}} = 1 \).

If \( |f(x)| < 1 \) for all \( x \in X \) then, from (1.8.1), it follows that \( \|f^n\| < 1 \) for \( n \gg 0 \). So \( \|f\|_{\text{sp}} < 1 \). This contradiction shows the existence of \( x_0 \in X \) with \( |f(x_0)| = \|f\|_{\text{sp}} \).

(1.9) **Further structure theorems on Tate-algebras.**

(1.9.1) (GERRITZEN): If \( k \) is (quasi-)complete then any Tate-algebra \( A/k \) is japanese (i.e., integral extensions of \( A \) in a finite field extension are finite modules over \( A \)).
2. Affine holomorphic spaces.

(2.1) Let $A$ be a Tate-algebra, defined over a field $k$. Let $X = \text{Sp}(A)$ denote the collection of all maximal ideals of $A$. For every $x \in X$, the residue field $k(x) = A/x$ is a finite extension of $k$ and has therefore a unique valuation, always denoted by $\nu_x$, extending the valuation of $k$. For $x \in X$ and $f \in A$, we denote by $f(x)$ the image of $f$ in $k(x)$.

The topology on $X$ is generated by the subsets $\{x \in X; |f(x)| \leq 1\}$ with $f \in A$. A base for this topology is the set of the so-called Weierstrass-domains $W(f_1, \ldots, f_n) = \{x \in X; |f_i(x)| \leq 1$ for all $i\}$.

A more general class of open (and closed) subsets of $X$ are the rational domains $R = R(f_0, \ldots, f_n) = \{x \in X; |f_i(x)| \leq |f_0(x)|$ for all $i\}$, where we have supposed that $f_0, \ldots, f_n$ have no common zero on $X$. With $R$, we associate a Tate-algebra $B$, $B = A(T_1, \ldots, T_n)/(f_1 - T_1 f_0, \ldots, f_n - T_n f_0)$.

(2.2) PROPOSITION.

(2.2.1) The map $A \xrightarrow{\varphi} B$ induces a continuous map $\text{Sp}(\varphi) : \text{Sp}(B) \to \text{Sp}(A)$. The image is $R$ and $\text{Sp}(\varphi) : \text{Sp}(B) \to R$ is a homeomorphism.

(2.2.2) For every (k-algebra homomorphism) $\varphi : A \to C$ of Tate-algebras with $\text{Sp}(\varphi)(\text{Sp}(C)) \subseteq R$ there is a unique $\chi : B \to C$ with $\chi \varphi = \varphi$.

Proof.

(2.2.1) For any k-algebra homomorphism $\varphi$, the induced map $\text{Sp}(\varphi)$ is continuous. For the given $B$, one easily verifies that $\text{Sp}(\varphi) : \text{Sp}(B) \to R$ is a homeomorphism.

(2.2.2) The map $\chi : B \to C$ is uniquely determined by $\chi(T_i)$ $(i = 1, \ldots, n)$ and $\chi(T_i) = \frac{\varphi(f_i)}{\varphi(f_0)}$ must hold. The existence of $\chi$ follows from § 1 (1.8.4). Namely, the elements $g_i = \frac{\varphi(f_i)}{\varphi(f_0)}$ in $C$ satisfy:

$|g_i(x)| \leq 1$ for all $x \in \text{Sp}(C)$.

Hence, the set $\{|g_1, \ldots, g_n|; \alpha_1, \ldots, \alpha_n \geq 0\}$ is bounded and the map

$\tilde{\chi} : A(T_1, \ldots, T_n) \to C$,

given by
\[ \sum_{\alpha} a_{\alpha} T_{\alpha}^{\alpha_1} \cdots T_{\alpha}^{\alpha_n} \rightarrow \sum_{\alpha} q_{\alpha} a_{\alpha} g_{\alpha} \cdots g_{\alpha} \] (with \( a_{\alpha} \in A \)), \( \lim_{\alpha} a_{\alpha} = 0 \)
is a \( k \)-algebra homomorphism. The kernel of \( \chi \) contains \( (f_1 - T_{f_0}, \ldots, f_n - T_{f_n}) \) and \( \chi \) induced the required \( \chi : B \rightarrow C \).

(2.3) For every rational domain \( R = R(f_0, \ldots, f_n) \), we define \( P(R) = A(T_1, \ldots, T_n)/(f_i - T_i f_0)_{i=1}^n \).

According to (2.2.2), \( P(R) \) does not depend on the choice of \( \{f_0, \ldots, f_n\} \) and moreover \( R \rightarrow P(R) \) is a pre-sheaf defined on the base \( \{R : R \text{ rational}\} \). Let us denote by \( H_X \) the sheaf on \( X \) (with the usual topology) associated with \( P \).

(2.4) Results.

(2.4.1) For \( x \in X \), the stalk \( H_{x,x} \) is a local analytic ring (i.e., a finite extension or a ring of convergent power series over \( k \)).

(2.4.2) The natural map of the localisation of \( A \) at \( x : A_x \rightarrow H_{x,x} \), induces an isomorphism for the completions of those local rings, \( A_x \rightarrow H_{x,x} \).

(2.4.3) For a rational domain \( R \) with \( B = P(R) \), the map \( \varphi : A \rightarrow B \) induces an isomorphism of ringed spaces \( (\text{Sp } B, H_{\text{Sp } B}) \rightarrow (R, H_X(R)) \).

Proof. - For \( X = \text{Sp}(k(T_1, \ldots, T_n)) = \{(t_1, \ldots, t_n) \in k^n, \forall t_i | \leq 1\} \) all this is easily verified. All the operations: completion, localisation, forming of \( H \), commute with taking residues w.r.t. an ideal \( I \subset k(T_1, \ldots, T_n) \). From this observation the general case follows.

(2.5) Definition. - An open subset \( Y \subset X = \text{Sp } A \) is called affine if there exists a Tate-algebra \( B \) and a morphism \( \varphi : A \rightarrow B \) which induces an isomorphism of ringed spaces \( (\text{Sp } B, H_{\text{Sp } B}) \rightarrow (Y, H_X(Y)) \).

(2.6) Remarks. - The ringed space \( (X, H_X) \) is an example of what H. CARTAN and S. ABHYANKAR would call a \( k \)-analytic space. Since \( X \) is totally disconnected, the sheaf \( H_X \) is very big. In particular, \( \Gamma(X, H_X) \nsubseteq A \).

Note that \( A \rightarrow \Gamma(X, H_X) \) is injective, since the map
\[ A \rightarrow \Gamma(X, H_X) \rightarrow \Pi_{x \in X} H_{x,x} \rightarrow \Pi_{x \in X} H_{x,x} \rightarrow \Pi_{x \in X} H_{x,x} \rightarrow \Pi_{x \in X} H_{x,x} \]
is injective.

To get something interesting, we have to consider on \( X \) a Grothendieck-topology instead of the ordinary topology. For this purpose, we have introduced open affine subsets of \( X \). Our definition is (with a slight modification), the one of GERRIT-ZEN-GRAUERT ([6], p. 162). Afterwards, we will show that \( Y \) determines the algebra \( B \) (this is of course clear for rational domains \( Y \)). It follows that \( Y \) is an affine open subset in the sense of J. TATE ([16], p. 270). (It is immediate
that an affine open subset in the sense of J. Tate is also an affine open set in the sense of (2.5)).

In order to see what this Grothendieck topology on $X$ should be, we have to find "gluing-properties" for the pre-sheaf $P$.

(2.7) Lemma.

(2.7.1) If $Y_1, Y_2 \subset X$ are rational domains, then so is $Y_1 \cap Y_2$. Moreover

$$P(Y_1 \cap Y_2) = P(Y_1) \otimes_A P(Y_2).$$

(2.7.2) If $Y_1 \subset Y_2 \subset X$ are open subsets such that $Y_2$ is rational in $X$ and $Y_1$ is rational in $Y_2$, then $Y_1$ is rational in $X$.

Proof.

(2.7.1): Let $Y_1 = R(f_0, \ldots, f_n)$ and $Y_2 = R(g_0, \ldots, g_m)$, then

$$Y_1 \cap Y_2 = R(g_0, f_0, g_1, f_1, \ldots, g_m, f_m).$$

Moreover

$$P(Y_1 \cap Y_2) = A(T_{ij} ; 1 \leq i, j \leq n, m)/(f_i g_i - T_{ij} f_0 g_0)$$

is easily seen to be isomorphic with

$$A(T_i)/(f_i - T_i f_0) \otimes A(S_j)/(g_j - S_j g_0).$$

(2.7.2): Let $Y_2 = R(g_0, \ldots, g_m)$ and let

$$f_0, \ldots, f_n \in A(S_1, \ldots, S_m)/(g_j - S_j g_0)$$

define $Y_1$ as a rational subset of $Y_2$. Elements $f_0', \ldots, f_n' \in P(Y_2)$ such that the $||f_i' - f_i||$ are very small define the same rational subset of $Y_2$. So we may suppose that $f_0, \ldots, f_n$ are represented by elements in $A[S_1, \ldots, S_m]$ of total degree $\leq N$. We may replace $f_0, \ldots, f_n$ by $g_0 f_0, \ldots, g_0 f_n$. Hence, we may suppose that $f_0, \ldots, f_n \in A$. For suitable constants $\lambda_0, \ldots, \lambda_m \in k^*$ we have on $Y_1$:

$$|f_i(x)| \geq |\lambda_i g_i(x)| \text{ for all } i \text{ and } x \in Y_1.$$

And thus $Y_1 = Y_2 \cap R(f_0, \ldots, f_n, \lambda_0 g_0, \ldots, \lambda_m g_m)$ is rational in $X$.

(2.8) Theorem. - For any finite covering $\mathcal{U} = (X_i)$ of $X$ by rational domains, the Cech-complex $c_\mathcal{U}$ is universally acyclic (i.e., $c_\mathcal{U} \otimes_A M$ is acyclic for every normed $A$-module $M$).

Proof. - We follow J. Tate ([16], p. 272). First two special cases of coverings.

(2.8.1) Lemma. - Let $f \in A$ and put

$$X_1 = \{x \in X; |f(x)| \leq 1\} \text{ and } X_2 = \{x \in X; |f(x)| \geq 1\}.$$
Then the covering \{X_1, X_2\} of \(X\) is u. a. (universally acyclic).

(2.8.2) LEMMA. Let \(f_0, \ldots, f_n \in A\) satisfy \(\max_i |f_i(x)| = 1\) for all \(x \in X\). Then the covering of \(X\) by \(X_i = \{x \in X ; |f_i(x)| = 1\} \) \((i = 0, \ldots, n)\) is u. a.

Proof. - J. TATE ([16] lemma 8.3 and 8.4) shows that both coverings have a continuous \(A\)-linear homotopy \(\mathcal{C}_X \rightarrow \mathcal{C}_Y\). This induces a homotopy \(\mathcal{C}_X \rightarrow \mathcal{C}_Y\) on \(\mathcal{C}_X \rightarrow \mathcal{C}_Y\).

Now we need some general hocus pocus to do the general case:

(2.8.3) LEMMA. Let \(\mathcal{X}\) and \(\mathcal{Y}\) be coverings of \(X\) (by finitely many affine open subsets). Suppose that \(\mathcal{X}/\mathcal{Z}\) is u. a. for every \(\mathcal{Z}\) which is an intersection of elements in \(\mathcal{Y}\).

If \(\mathcal{Y}\) is u. a. then \(\mathcal{X}\) is u. a.

We consider the double complex \(\mathcal{C}_{\mathcal{X}} \otimes \mathcal{C}_{\mathcal{Y}}\). It is given that

1° \(\mathcal{C}_{\mathcal{X}} \otimes \mathcal{C}_{\mathcal{Y}}\) is exact.

2° \(\mathcal{C}_{\mathcal{Y}} \otimes \mathcal{C}_{\mathcal{X}}\) is exact.

So, all rows and columns, except possibly \(\mathcal{C}_{\mathcal{X}} \otimes \mathcal{C}_{\mathcal{Y}}\), are exact. Hence \(\mathcal{C}_{\mathcal{X}} \otimes \mathcal{C}_{\mathcal{Y}}\) is exact. The same reasoning holds for \(\mathcal{C}_{\mathcal{X}} \otimes \mathcal{C}_{\mathcal{Y}}\).

(2.8.4) Continuation of the proof of (2.8). - First we observe: If \(\mathcal{X}\) and \(\mathcal{Y}\) are u. a., then so is \(\mathcal{X} \cap \mathcal{Y} = \{X \cap Y ; X \in \mathcal{X}, Y \in \mathcal{Y}\}\). Indeed, by (2.8.3) applied to \(\mathcal{X}' = \mathcal{X} \cap \mathcal{Y}\) and \(\mathcal{Y}' = \mathcal{Y}\), this follows.

Let us start with any finite covering \(\mathcal{X} = \{\mathcal{X}_i^{(i)} ; \ldots, \mathcal{X}_n^{(i)}\}\) by rational domains. Choose \(\varepsilon > 0\) such that \(|f_i^{(i)}(x)| > \varepsilon\) for all \(x \in \mathcal{X}_i^{(i)}\). Let \(\{\mathcal{Y}_1, \ldots, \mathcal{Y}_s\}\) denote the set \(\{\mathcal{X}_i^{(i)}\}\), and let, for every subset \(\sigma\) of \(\{1, \ldots, s\}\),

\[\mathcal{Y}_\sigma = \{x \in X ; |g_i(x)| < \varepsilon \text{ for } i \in \sigma \text{ and } |g_i(x)| > \varepsilon \text{ for } i \notin \sigma\}.

The covering \(\mathcal{Y}_\sigma = \{\mathcal{Y}_\sigma\}^{\text{all } \sigma}\) is the intersection of \(s\) coverings of the type in (2.8.1). Hence \(\mathcal{Y}_\sigma\) is u. a. In order to show that \(\mathcal{X}\) is u. a., it suffices to see that \(\mathcal{X}/\mathcal{Z}\) is u. a. for any \(\mathcal{Z}\) which is an intersection of elements of \(\mathcal{Y}\).

This new covering \(\mathcal{X}' = \mathcal{X}/\mathcal{Z}\) consists of Weierstrass-domains in \(\mathcal{Z}\), i.e., sets of the type \(\{x \in \mathcal{Z} ; |f_i(x)| \leq 1\text{ for some } i's\}\). Let \(\{h_1, \ldots, h_t\}\) denote the set of all functions occurring in those inequalities, and let \(\mathcal{Y}' = \{\mathcal{Y}_\sigma\}\) denote the covering of \(\mathcal{Z}\) given by

\[\mathcal{Y}'_\sigma = \{x \in \mathcal{Z} ; |h_i(x)| < 1 \text{ for } i \in \sigma \text{ and } |h_i(x)| > 1 \text{ for } i \notin \sigma\}.

Again \(\mathcal{Y}'\) is u. a. and in order to show that \(\mathcal{X}'\) is u. a., we have to show \(\mathcal{X}'/\mathcal{Z}\) is u. a. This last covering however is of the type mentioned in (2.8.2), and the proof is finished.

(2.9) THEOREM (GERRITZEN-GRAUERT [6], p. 178). - An open affine subset of \(X = \text{Sp}(A)\) is a finite union of rational domains.
Proof. — The proof is quite long. The essential part is a result on Runge embeddings (There seems to be a gap in the proof.).

**(2.10) COROLLARY.** — The open affine subset $Y$ of $X$ determines uniquely the morphism of Tate-algebras $A \rightarrow B$ for which $(\text{Sp } B_0, H_{\text{Sp } B_0}) \rightarrow (Y, H_X/Y)$ is an isomorphism.

Proof. — Put $Y = \bigcup_{i=1}^{n} X_i$ where the $X_i$ are rational domains in $X$. Then the $X_i$ are also rational in $Y$ and (2.8) implies $B = \ker(\bigoplus P(X_i) \rightarrow P(X_i \cap X_j))$.

**(2.11) COROLLARY.** — Any finite covering of $X$ by affine open subsets is universally acyclic.

Proof. — Follows from (2.9), (2.8) and (2.8.3).

**(2.12) Remarks.** — A morphism $\text{Sp}(\varphi) : Y = \text{Sp}(B) \rightarrow X = \text{Sp}(A)$ is called a Runge-map when $\varphi : A \rightarrow B$ has a dense image. The proof of (2.9) relies on the following proposition:

Let $u = \text{Sp}(\varphi) ; Y = \text{Sp}(B) \rightarrow X = \text{Sp}(A)$ be given, and let $f_0, \ldots, f_n \in A$ be given such that $(f_0, \ldots, f_n)A = A$. Put

$$X_{\varepsilon} = \{x \in X ; |f_1(x)| \leq \varepsilon |f_0(x)| \text{ for all } x\} \text{ and } Y_{\varepsilon} = u^{-1}(X_{\varepsilon}).$$

If $u : Y_{\varepsilon} \rightarrow X_{\varepsilon}$ is Runge then for $\varepsilon$ close to 1, $u : Y_{\varepsilon} \rightarrow X_{\varepsilon}$ is also a Runge-map.

**(2.13) For our purpose, we define a Grothendieck-topology on a topological space $X$ as follows:

1° A family $\mathcal{F}$ of open subsets of $X$ such that $X \in \mathcal{F}$; $U, V \in \mathcal{F} \Rightarrow U \cap V \in \mathcal{F}$.

2° For every $U \in \mathcal{F}$ a set $\text{Cov}(U)$ of coverings by elts in $\mathcal{F}$, i.e., any

$$u = (U_i) \in \text{Cov}(U)$$

satisfies: all $U_i \in \mathcal{F}$ and $U U_i = U$.

3° $\{U \rightarrow U\} \in \text{Cov}(U)$ for all $U \in \mathcal{F}$.

4° $u \in \text{Cov}(U)$ and $V \subseteq U, V \in \mathcal{F}$ then $U/V \in \text{Cov}(V)$.

5° $U_i \in \text{Cov}(U_i)$ and $(U_i) \in \text{Cov}(U)$ then $U U_i \in \text{Cov}(U)$.

We remark that the object defined above is in fact a special case of a pre-topology in the sense of Grothendieck. So we can use the whole machinery of sheaves and cohomology for a Grothendieck-topology.

**(2.14) An affine holomorphic space $(X, \mathcal{O}_X)$ is the following:

1) $X = \text{Sp } A$ for some Tate-algebra $A$. }
2) \( S \) consists of all open affine subsets of \( X \).

3) For all \( U \in S \), \( \text{Cov}(U) \) consists of all coverings of \( U \) by elements in \( S \) which have a finite subcovering.

4) \( \mathcal{O}_X \) is the sheaf (for \( S \)) of rings defined by \( \mathcal{O}_X(U) = \) the unique Tate-algebra \( B \) for which \( A \to B \) with an immersion \( U = \text{Sp} B \to \text{Sp} A \).

\( \mathcal{O}_X \) is a sheaf according to (2.11).

(2.15) A holomorphic space \( (X, S, \mathcal{O}_X) \) is a topological space \( X \) with a Grothendieck-topology \( S \) and a sheaf of rings \( \mathcal{O}_X \) such that \( \mathbb{I} (U_i) \in \text{Cov}(X) \) with \( (U_i, S/U_i, \mathcal{O}_X/U_i) \) is an affine holomorphic space for all \( i \).

[Note. - \( U \in S \) is called affine if \( (U, S/U, \mathcal{O}_X/U) \) is an affine holomorphic space. If \( U \) is affine and \( V \in S \) then \( U \cap V \) is an affine open subset of \( U \).]

(2.16) Some properties of affine holomorphic spaces (see [10]).

(2.16.1) \( \text{Hom}_{\text{alg}}(A, B) \to \text{Hom}(\text{Sp} B, \text{Sp} A) \).

(2.16.2) Definition. - An \( \mathcal{O}_X \)-module \( M \) on \( X = \text{Sp} A \) is called coherent if there exists a finitely generated \( A \)-module \( N \) such that the sheaf \( M \) is isomorphic with the sheaf \( U \to \mathcal{O}_X(U) \otimes_A N \) (\( U \) open affine in \( X \)).

(2.16.3) Proposition. - An \( \mathcal{O}_X \)-module \( M \) is coherent if there exists a \( (U_i) \in \text{Cov}(X) \)
such that \( N/U_i \) is coherent for each \( i \).

If \( M \) is coherent, then

\[ H^i(X, M) = 0, \quad i > 0 \]

\[ H^0(X, M) = N, \quad \text{and} \ M \ \text{is associated with the} \ A-\text{module} \ N. \]

Proof. - The second part of the proposition follows directly from (2.11). The first part is a property of "descent" for \( A \to B = \bigoplus \mathcal{O}_X(U_i) \), i.e. consider \( A \to B \to B \otimes_A B \) (note \( B \otimes_A B = \bigoplus_{i,j} \mathcal{O}_X(U_i \cap U_j) \)), then:

(i) \( A \)-\( B \)-module \( M(fg) \) is isomorphic with some \( N \otimes_A B \) if there exists a \( B \otimes_A B \)-module isomorphism

\[ M \otimes_B (B \otimes_A B) \to N \otimes_B (B \otimes_A B). \]

(ii) For \( fg \) \( A \)-modules \( N_1 \) and \( N_2 \), the sequence

\[ \text{Hom}_A(N_1, N_2) \to \text{Hom}_B(N_1 \otimes_A B, N_2 \otimes_A B) \to \text{Hom}_B(N_1 \otimes_A (B \otimes_A B), N_2 \otimes_A (B \otimes_A B)). \]

This "descent"-property is proved by R. KNEHSL.

(3.1) (Quasi-)Stein spaces.

Definition. - A holomorphic space $X$ is called a quasi-Stein space if

$$\mathfrak{I}(X_1)_{1 \in \mathbb{N}} \in \mathcal{C}(X),$$

an affine covering with

1) $X_i \subset X_{i+1}$ for all $i$.

2) $\mathcal{O}_X(X_{i+1}) \rightarrow \mathcal{O}_X(X_i)$ has dense image.

$X$ is called a Stein-space if a more restrictive property holds:

$$\prod f_1, \ldots, f_r \in \mathcal{O}_X(X_{i+1}).$$

with

(a) $X_i = \{x \in X_{i+1}; |f_j(x)| \leq 1 \text{ for all } j\}$.

(b) $f_1/a, \ldots, f_r/a$ (for some $a \in k^*$) are topological generators of $\mathcal{O}_X(X_{i+1})$.

(3.1.1) Theorem (R. Kiehl [10]). - If $M$ is a coherent $\mathcal{O}_X$-module (i.e., $M/U$ coherent for every open affine $U \subset X$) and $X$ is quasi-Stein, then

1° $M(X) \rightarrow M(X_i)$ has dense image.

2° $H^i(X, M) = 0$ for $i > 0$.

3° $M_X$ is generated over $\mathcal{O}_X$, by $M(X)$.

Proof. - Easy consequence of (2.16.3) + definition (3.1).

(3.1.2) Theorem (Kiehl [10]; Lütkebohmert [11]). - Let $X$ be a Stein-space of dimension $n$, which can locally be embedded in a $N$-dimensional space $/k$. Then $X$ has an embedding into $k^{N+n+1}$.

(3.1.3) Examples. - $k^n$ and $G = k^*n$ are Stein-spaces.

The structure of $G$ can be given by:

$$G = U x_m; x_m = \{(x_1, \ldots, x_n) \in k^n; \pi^m \leq |x_i| \leq |\pi|^m \text{ all } i\}. $$

(Here $\pi \in k^*$ and $0 < |\pi| < 1$.)

An open subset $U \subset G$ is called open affine if $U$ is open affine in some $X_n$.

For an open affine $U \subset G$, it is clear what $\mathcal{C}(U)$ is. For $G$, $\mathcal{C}(G)$ consists of the coverings $(U_i)$ be open affine sets such that $(U_i)/U \in \mathcal{C}(U)$ for every open affine $U \subset G$.

With $(X_i) \in \mathcal{C}(G)$, one calculates:

$$\mathfrak{C}(G) = \lim \mathfrak{C}(X_i) = \{\sum_{\alpha \in \mathbb{Z}^n} a_{x_1}^\alpha \ldots x_n^\alpha | \text{ convergent on all of } G\}.$$

More generally, any algebraic variety has a unique structure of holomorphic space. If the variety is affine then the holomorphic space is a Stein-space.
(3.2) **Proper mappings.** - A morphism \( f : X \to Y \) of holomorphic spaces is called **proper** if the following holds.

(a) \( f \) is **separated**, i.e., \( X \to X \times_Y X \) is a closed embedding.

(f) There is \((Y_i)_{i \in I} \subseteq \text{Cov}(Y)\), with each \( Y_i \) affine open, and for each \( i \in I \) there are two finite coverings \((U_{ij})_{j=1}^{n_i}, (V_{ij})_{j=1}^{n_i}\) of \( f^{-1}(Y_i) \) by affine sets such that \( U_{ij} \preceq V_{ij} \) (all \( i, j \)).

Here \( U \preceq V \) for affine open sets \( U \), \( V \), means the following; there is an \( \epsilon > 0, 0 < \epsilon < 1 \), and an embedding \( V \subseteq \{(\lambda_1, \ldots, \lambda_n) \in k^n; \quad \text{all } |\lambda_i| \leq 1\} \) such that \( U \subseteq \{(\lambda_1, \ldots, \lambda_n) \in k^n; \quad \text{all } |\lambda_i| \leq \epsilon\} \).

A holomorphic space \( X \) is called **compact (or complete)** if "\( X \to \text{point} \)" is proper.

(3.2.1) **THEOREM (R. KIEHL [9])**. - \( f : X \to Y \) proper, \( M \) a coherent \( \mathcal{O}_X \)-module then all \( R^i \mathcal{L}_f \text{M} \) are coherent \( \mathcal{O}_Y \)-modules.

**COROLLARY.** - If \( X \) is compact and \( M \) is a coherent \( \mathcal{O}_X \)-module, then \( \dim H^i(X, M) < \infty \) for all \( i \).

(3.3) **Projective spaces.** - \( \mathbb{P}^n(k) \) is a **compact holomorphic space**. The well known GAGA-properties hold:

1° 1.1. Correspondance between algebraic coherent sheaves \( \mathcal{N} \) and the coherent \( \mathcal{O}_X \)-modules \( \mathcal{M} \).

2° \( H^i_{\text{alg}}(X, \mathcal{N}) \cong H^i_{\text{alg}}(X, \mathcal{M}) \).

3° Any analytic subset of \( \mathbb{P}^n(k) \) is algebraic.

(3.4) **The sheaves \( \mathcal{O}^*, \mathfrak{M}, \mathfrak{M}^*, \text{Div} \).**

(3.4.1) \( \mathcal{O}^* \) is defined by \( U \to \mathcal{O}_X(U)^* \) (\( ^* \) = invertible elements). This is a sheaf since \( \mathcal{O}(U) \to \bigoplus \mathcal{O}(U_i) \otimes \bigoplus \mathcal{O}(U_i \cap U_j) \) is exact for every \( (U_i) \in \text{Cov}(U) \).

(3.4.2) \( \mathfrak{M} \) = the sheaf of meromorphic functions is defined by \( U \to \text{Qt}(\mathcal{O}_X(U)) \) for every affine open \( U \) (\( \text{Qt} \) = total quotient ring).

**Proof.** - We have to verify that this is in fact a sheaf on every affine open space \( U \subseteq X \). Let \((U_i) \in \text{Cov}(U)\) and let \( (t_i/n_i) \in \bigoplus \text{Qt}(\mathcal{O}(U_i)) \) satisfy \( t_i/n_i = t_j/n_j \) in \( \text{Qt}(\mathcal{O}(U_i \cap U_j)) \) (all \( i, j \)). Then we have to show the existence of \( t/n \in \text{Qt}(\mathcal{O}_X(U)) \) with image \( t_i/n_i \) in every \( \text{Qt}(\mathcal{O}(U_i)) \).

One proceeds as follows: let \( I(U_1) = \{s \in \mathcal{O}(U_1); \; st_i \in n_i \mathcal{O}(U_i)\} \).

Then \( I(U_1) \otimes \mathcal{O}_X(U_i \cap U_j) = I(U_j) \otimes \mathcal{O}_X(U_i \cap U_j) \).

By (2.16.3), there is an ideal \( I \subset \mathcal{O}_X(U) \) with \( I/U_i = I(U_i) \) for all \( i \).
contains a non-zero divisor, otherwise \( I_z = 0 \) for some \( z \in \mathfrak{O}_X(U) \), \( z \neq 0 \). And also \( I(U_1)z = 0 \), \( \forall i \). But each \( I(U_1) \) contains a non-zero divisor. Hence \( z/U_1 = 0 \), \( \forall i \) and so \( z = 0 \). Take \( n \in I \), \( n \neq 0 \), \( n \) a non-zero divisor. Then \( t_i/n_i = s_i/n \), \( \forall i \) and the \( s_i \) satisfy \( s_i/U_1 \cap U_j = s_j/U_1 \cap U_j \). So the \( s_i \) glue to an element \( t \in \mathfrak{O}_X(U) \).

(3.4.3) \( M^* \) is defined by \( M^*(U) = \text{Qt}(\mathfrak{O}(U))^* = M(U)^* \) for every open affine \( U \subset X \). As in (3.4.2) this is a sheaf.

(3.4.4) The sheaf of divisors \( \text{Div} \) is defined by an exact sequence

\[
0 \rightarrow \mathfrak{O}^* \rightarrow M^* \rightarrow \text{Div} \rightarrow 0.
\]

(3.4.5) As in the classical case,

\[
H^i(X, \mathfrak{O}^*) \cong \text{invertible sheaves on } X/\text{isomorphism}.
\]

Proof. - The usual one

\[
H^i(X, \mathfrak{O}^*) = \lim_{\text{U \in Cov}(X)} H^i(U, \mathfrak{O}^*).
\]

(3.4.6) If \( X = \text{Sp} A \) is affine, then there is a 1:1 correspondence between invertible sheaves on \( X \) and projective rank 1 modules over \( A \). Hence

\[
H^i(X, \mathfrak{O}_X^*) = \text{rank 1 projective } A\text{-modules / isomorphism}[2].
\]

(3.4.7) Suppose \( X = \text{Sp} A \), and \( A \) is regular, then \( H^i(X, \mathfrak{O}_X^*) = \text{Class groups of } A \). In particular,

\[
A \text{ is a unique factorisation domain } \iff H^i(X, \mathfrak{O}^*) = 0.
\]

(3.4.8) PROPOSITION (L. GRUSON [8]). - Let \( X = \text{Sp} A \), and let \( A \) be regular. If \( A \) has unique factorisation then also \( A(T) \) and \( A(T^*, T^{-1}) \) have unique factorisation.

(3.4.9) CONSEQUENCE. - Let \( G = k^n \) then \( H^i(G, \mathfrak{O}_G^*) = 0 \).

Proof. - It suffices to consider

\[
X_n = \{(x_1, \ldots, x_n) \in k^n; \quad |n| \leq |x_i| \leq |n|^{-1} \text{ for all } i\},
\]

where \( n \in k \), \( 0 < |n| < 1 \). We want to show that any invertible sheaf \( \mathfrak{F} \) on \( X_n \) is trivial (i.e. \( \cong \mathfrak{O}_{X_n}^* \)). Let \( \mathfrak{O}_{X_n} \) be the structure sheaf on

\[
X_n = \{x_n \in k; \quad |x_n| \leq |n|\}.
\]

Then

\[
(\mathfrak{O}_{X_n}^* \times \{x_n \in k; \quad |x_n| = |n|\}) \cong (\mathfrak{O}_{X_n}^* \times \{x_n \in k; \quad |x_n| = |n|\})
\]

because of (3.4.8). Hence by (2.16.3), \( \mathfrak{F} \) and \( \mathfrak{O}_{X_n} \) glue together to form an invertible sheaf

\[
\mathfrak{F}\text{ on } X_n = \{x_n \in k; \quad |x_n| \leq |n|^{-1}\}.
\]

But \( \mathfrak{F}^* \) is trivial by (3.4.8). Hence also \( \mathfrak{F} \) is trivial.
4. Analytic tori and abelian varieties.

The results of this sections are mainly due to L. GERRITZEN ([2], [4]).

4.1) A subgroup $\Gamma$ of $G = \mathbb{C}^n$ is called discrete if

$$\Gamma \cap \{ x \in G ; \quad \epsilon \leq \| x \| \leq \epsilon^{-1}, \quad \forall \epsilon \}$$

is finite for all $\epsilon \leq 1$.

The map $\lambda : G \to \mathbb{R}^n$ defined by

$$\lambda(x_1, \ldots, x_n) = (-\log |x_1|, \ldots, -\log |x_n|)$$

is a group homomorphism. It is easily seen that

$$\Gamma \text{ is discrete } \iff \lambda(\Gamma) \subset \mathbb{R}^n \text{ is discrete and ker } \lambda/\Gamma \text{ is finite}.$$ 

We are interested in the case where $\Gamma$ has maximal rank ($= n$), and $\Gamma$ has no torsion elements. Hence $\lambda(\Gamma)$ is a lattice in $\mathbb{R}^n$.

**Proposition.** - The quotient $G/\Gamma$ is called a holomorphic torus; $G/\Gamma$ has a unique structure of holomorphic space over $\mathbb{C}$ such that $\pi : G \to G/\Gamma$ is a holomorphic map. Moreover $G/\Gamma$ is "compact".

**Proof.** - For convenience, we do only $n = 1$; $n > 1$ can be done in the same way. Then $\Gamma = \langle q \rangle$, and we may suppose $q = 1$. The topological space $G/\Gamma$ can be covered by the images $X_1, X_2$ under $\pi$ of

$$X_1 = \{ x \in G ; \quad |q| \leq |x| \leq |n_1| \leq 1 \}$$

$$X_2 = \{ x \in G ; \quad |n_2| \leq |x| \leq |n_1| \}$$

where $|q| < |n_2| < |n_1| < 1$.

Of course, $\pi/X_1 : X_1 \to \tilde{X}_1$ is a homeomorphism. Further $\tilde{X}_1 \cap \tilde{X}_2$ is the disjoint union of the images (under $\pi$) of

$$\{ x \in k ; \quad |x| = 1 \} \quad \text{and} \quad \{ x \in k ; \quad |n_2| \leq |x| \leq |n_1| \}.$$ 

So $\tilde{X}_1$ and $\tilde{X}_2$ are glued in a nice way, and $G/\Gamma$ becomes a holomorphic space.

One can make another covering of $G/\Gamma$ by $Y_1, Y_2$ such that $Y_1 \ll X_1$. Hence $G/\Gamma$ is compact.

4.2) Let $T = G/\Gamma$ have dimension $n$. Then

$$H^*(G/\Gamma, \mathcal{O}) = \mathbb{Z}^n$$

$$H^*(T, \mathcal{O}) = \mathbb{C} \quad \text{for any constant sheaf } \mathcal{O}.$$ 

**Proof.** - Again we consider only $n = 1$. Then $H^*(G/\Gamma, \mathcal{O})$ is given by the exact sequence

$$0 \to \mathcal{O}^*(G/\Gamma) \to \mathcal{O}^*(\tilde{X}_1) \oplus \mathcal{O}^*(\tilde{X}_2) \to \mathcal{O}^*(\tilde{X}_1 \cap \tilde{X}_2) \to H^1(G/\Gamma, \mathcal{O}) \to 0,$$
because $H^1(Z, \mathcal{O}^*) = 0$ for $Z = \tilde{X}_1 \setminus \tilde{X}_2$ or $\tilde{X}_1 \cap \tilde{X}_2$. The same covering can be used to calculate $H^1(T, \mathcal{O})$.

(4.3) Our aim is to calculate the field of meromorphic functions on $G/\Gamma$, $\mathbb{M}(G/\Gamma)$.

(4.3.1) **Proposition.** - $\mathbb{M}(G) = \text{the quotient field of}$

$$\mathcal{O}(G) = \{ \sum_{\alpha_1, \ldots, \alpha_n} \alpha_1 \mathbb{Z}_1 \cdots \mathbb{Z}_n \text{, everywhere convergent} \}.$$ 

**Proof.** - $\mathbb{M}(G) = \lim_{\rightarrow} \mathbb{M}(\mathcal{X}_i)$ with

$$\mathcal{X}_i = \{(z_1, \ldots, z_n) \in \mathbb{K}^n \mid |z_j| \leq |z_i| \leq |z_j| \text{ for all } j \}.$$ 

Given a projective system $(a_i/b_i)$ in $\lim \mathbb{M}(\mathcal{X}_i)$, we can make ideals

$$I_i = \{ t \in \mathcal{O}(\mathcal{X}_i) \mid t(a_i/b_i) \in \mathcal{O}(\mathcal{X}_i) \}; \quad I_{i+1}/|X_1| = I_1.$$ 

So we find a coherent sheaf of ideals $\mathcal{I} \subset \mathcal{O}$. Since $G$ is a Stein-space, we have $\mathcal{I}(G) \neq 0$. Take $n \in \mathcal{I}(G)$ and $n \neq 0$. Then $t_1/h_1 = a_i/b_i$ in $\mathcal{O}(\mathcal{X}_1)$ for suitable $t_i \in \mathcal{O}(\mathcal{X}_1)$. Since $t_{i+1}/h_{i+1} = t_i$, we find an element $t \in \mathcal{O}(G)$ with $t/h_i = t_1$, $\forall \ i$. Hence $t/n = \lim (a_i/b_i)$.

Using further $H^1(G, \mathcal{O}^*) = 0$, we can choose $t$ and $n$ such that

$$g \cdot c. d. (t_x, h_x) = 1 \text{ in } \mathcal{O}_{G,x} \text{ for every point } x \in G.$$ 

(4.3.2) **Proposition.** - The group $\Gamma$ acts on $G$ and $\mathbb{M}(G)$. For this action, we have $\mathbb{M}(G)\Gamma = \mathbb{M}(G/\Gamma)$.

**Proof.** - More or less clear.

(4.3.3) **Definition.** - An holomorphic function $f : G \to k$ is called a theta-function for $(G, \Gamma)$ if for every $\gamma \in \Gamma$ there exists a function $Z_\gamma \in \mathcal{O}(G)$ with

$$f(z) = Z_\gamma(z) f(\gamma z).$$ 

It follows easily that $Z_\gamma$ has no zero's in $G$ and hence $Z_\gamma$ must be an element of the group

$$A = \{ \lambda z_1^{\alpha_1} \cdots z_n^{\alpha_n} \mid \lambda \in \mathbb{K}^*, \alpha_1, \ldots, \alpha_n \in \mathbb{Z} \} = \mathcal{O}(G)^*.$$ 

(4.3.4) **Proposition.** - Any $f \in \mathbb{M}(G/\Gamma)$ can be written as $f = \theta_1/\theta_0$, where $\theta_0, \theta_1$ are theta-functions with the same "multiplicator" $Z_\gamma$.

**Proof.** - Write $f = \theta_1/\theta_0$ with $\theta_1 \in \mathcal{O}(G)$ and $\theta_1$ relatively prime. Then

$$f(\gamma z) = \frac{\theta_1(\gamma z)}{\theta_0(\gamma z)} = f(z).$$ 

Since $\theta_0, \theta_1$ are relatively prime, we find

$$\theta_i(z) = Z_\gamma(z) \theta_i(\gamma z) \quad (i = 0, 1) \text{ for some } Z_\gamma \in \mathcal{O}(G).$$
Construction of \( p \)-adic theta-functions. - In order to compute \( \Pi(G/\Gamma) \) the meromorphic functions on \( G/\Gamma \), we have to construct theta functions with a given "multiplicator" \( \gamma \mapsto Z_\gamma \).

(4.4.1) Lemma.

1° The multiplicator \( \gamma \mapsto Z_\gamma \) is a 1-cocycle in \( H^1(\Gamma, A) \), i.e.

\[
Z_{\gamma \gamma'}(z) = Z_\gamma(y z) Z_\gamma(z) \quad (\text{for all } \gamma, \gamma' \in \Gamma; z \in G).
\]

2° Any 1-cocycle \( \gamma \mapsto Z_\gamma \) (in \( H^1(\Gamma, A) \)) has the form \( (d(\gamma) \in k^*) \)

\[
Z_\gamma(z) = d(\gamma) \sigma(\gamma)(z) \quad \text{where } \sigma: \Gamma \to H = \{z_1, \ldots, z_n \in \mathbb{Z} \}.
\]

is a group homomorphism (\( H = \) all analytic characters on \( G \)).

Moreover \( d(\gamma \gamma') \cdot d(\gamma)^{-1} = \sigma(\gamma') \).

Define \( q: \Gamma \times H \to k^* \) by \( q(\gamma, h) = h(\gamma) \) then \( \sigma(\gamma')(\gamma) = q(\gamma', \sigma(\gamma')) \) and \( \Gamma \times \Gamma \to k^* \) given by \( (\gamma, \gamma') \mapsto q(\gamma, \sigma(\gamma')) \) is bilinear symmetric.

3° After possibly a finite field extension of \( k \) there is a symmetric bilinear form \( p: \Gamma \times \Gamma \to k^* \) and a group homomorphism \( c: \Gamma \to k^* \) such that

\[
Z_\gamma = c(\gamma) p(\gamma, \gamma) \sigma(\gamma)
\]

\[
p(\gamma, \gamma')^2 = q(\gamma, \sigma(\gamma'))
\]

Proof. - 1° and 2° are clear if one uses \( A = k^* \).

3° Choose a base \( \gamma_1, \ldots, \gamma_n \) of \( \Gamma \) and elements \( p(\gamma_i, \gamma_j) \) satisfying

\[
p(\gamma_i, \gamma_j) = p(\gamma_j, \gamma_i)
\]

The bilinear extension of \( p \) is symmetric and satisfies

\[
p(\gamma, \gamma')^2 = q(\gamma, \sigma(\gamma'))
\]

Moreover \( Z_\gamma = c(\gamma) p(\gamma, \gamma) \sigma(\gamma) \) for some function \( c: \Gamma \to k^* \).

Substitution in 1° guilds that \( c \) is a homomorphism.

(4.4.2) Definition. - Given a 1-cocycle \( Z \), we want to determine \( L(Z) \) the vector space of theta-functions with multiplicator \( Z \), i.e. the holomorphic function on \( G \) satisfying

\[
f(z) = Z_\gamma(z) f(y z) \quad (\gamma \in \Gamma, \, z \in G).
\]

To simplify matters, we introduce \( M \) = all formal expressions \( \Sigma_{\alpha \in H} a_\alpha h \) with coefficients \( a_\alpha \in k \). \( M \) is a vector space over \( k \) with some extra structure:

action of \( \Gamma \): \( (\Sigma a_\alpha h)^\gamma := \Sigma a_\alpha q(\gamma, h) \).

multipl. by elts in

\[
H: h' (\Sigma a_\alpha h) := \Sigma a_\alpha h' h.
\]
\[ L^0(Z) = \text{the elements of } M \text{ satisfying } f = \sum_{\gamma} f_{\gamma} \]
\[ = \text{the formal } o\text{-functions with cocycle } \]

(4.4.3) \text{Lemma.}

1° \( L^0(Z) \neq 0 \) if and only if there is \( h \in H \) such that \( \gamma_q = q(\gamma, h) \) for all \( \gamma \in \ker \sigma \).

2° If \( L^0(Z) \neq 0 \), then \( \dim L^0(Z) \leq \#(\text{torsion elements of } H/\sigma(\Gamma)) \).

Equality holds if \( \sigma \) is injective.

3° \( L(Z) \neq 0 \) if and only if \( L^0(Z) \neq 0 \) and \( |q(\gamma, \sigma(\gamma))| < 1 \) as soon as \( \sigma(\gamma) \neq 1 \).

4° If \( L(Z) \neq 0 \), then \( L(Z) = L^0(Z) \).

\textbf{Proof.} - We introduce the following notations: sub groups \( H', H'' \) of \( H \) and \( \Gamma' \) of \( \Gamma \) such that \( H' \cap H'' = H \); \( \sigma(\Gamma) \leq H' \) and \( H'/\sigma(\Gamma) \) is a finite group with representatives \( w_{1}, \ldots, w_{t} \); \( \Gamma' \cap \ker \sigma = \Gamma \).

Any \( f \in M \) has uniquely the form

\[ f = \sum_{i=1}^{n} t_{i} \gamma \in \Gamma' \text{, } h \in H' \] \[ a_{i_{1}, \gamma, h_{1}} Z_{\gamma} w_{1} h_{1} = (a_{i_{1}, \gamma, h_{1}} \in k) \cdot \]

Since \( Z(\gamma f(\gamma z)) = \sum_{i=1}^{n} a_{i_{1}, \gamma, h_{1}} q(\gamma, w_{1} h_{1}) Z_{\gamma} w_{1} h_{1} \); the condition \( f \in L^0(Z) \)

is equivalent with

\[ \begin{align*}
\sum_{i=1}^{n} a_{i_{1}, \gamma, h_{1}} q(\gamma, w_{1} h_{1}) &= a_{i_{1}, \gamma, h_{1}} \text{ for all } \gamma \in \Gamma', \\
\sum_{i=1}^{n} a_{i_{1}, \gamma, h_{1}} q(\gamma, w_{1} h_{1}) Z_{\gamma} &= a_{i_{1}, \gamma, h_{1}} \text{ for all } \gamma \in \ker \sigma.
\end{align*} \]

In another form, for some \( a_{i_{1}, h_{1}} \in k \), we have

\[ \begin{align*}
a_{i_{1}, \gamma, h_{1}} q(\gamma, w_{1} h_{1}) &= a_{i_{1}, \gamma, h_{1}} \\
a_{i_{1}, h_{1}} \neq 0 &\iff Z_{\gamma} = q(\gamma, (w_{1} h_{1})^{-1}) \text{ for all } \gamma \in \ker \sigma.
\end{align*} \]

From this \( 1° \) follows immediately; \( 2° \) also follows because \( H_{0} = \{ h \in H \mid q(\gamma, h) = 1 \text{ for all } \gamma \in \ker \sigma \} \)
is contained in \( H' \). So there is at most one \( h_{1} \) with \( a_{i_{1}, h_{1}} \neq 0 \).

Further explanation: since \( q \) is non-degenerate, the group \( H_{0} \) has

\[ \text{rank } = n - \text{rank}(\ker \sigma) = \text{rank } \sigma(\Gamma) \).

Further since \( q(\gamma, \sigma(\gamma)) \) is symmetric one has \( q(\ker \sigma, \sigma(\Gamma)) = 1 \) and \( H_{0} \supseteq \sigma(\Gamma) \). Hence \( H_{0} < H' \).

3° and 4°: We have to estimate the absolute values of the coefficients of \( f \in L^0(Z) \).

\[ a_{i_{1}, \gamma, h_{1}} Z_{\gamma} w_{1} h_{1} = a_{i_{1}, h_{1}} q(\nu, w_{1} h_{1}) c(\nu) p(\nu, \nu) \sigma(\nu) w_{1} h_{1} \cdot \]
Suppose \( a_{i,h} \neq 0 \) and \( \nu \neq 0 \). Convergence of the subsequence
\[
\sum_{n \geq 1} a_{i,h} q(n \nu, w_i h^n) c(n \nu) p(n \nu, n_0) \sigma(n \nu) w_i h^n \quad \text{(of } f \text{)}
\]
on all of \( G \) implies clearly \( |p(\nu, \nu)| < 1 \).

On the other hand if \( |p(\nu, \nu)| < 1 \) for all \( \nu \in \Gamma' \), \( \nu \neq 0 \), then
\[
\langle \nu, \nu' \rangle = - \log |q(\nu, \sigma(\nu'))|
\]
is a positive definite symmetric bilinear form on \( \Gamma' \times \Gamma' \). So \( \langle \nu, \nu' \rangle \) is an inner product on \( \Gamma' \otimes \mathbb{R} \) and
\[
\langle \nu, \nu \rangle \geq c \sum_{i=1}^{2} \nu_i^2 \quad (\nu = (\nu_1, \nu_n) \text{ and } c > 0).
\]
From this one easily sees that \( f \in L(\mathbb{Z}) \).

(4.5) **Algebraicity of** \( G/\Gamma \).

**THEOREM.** - The following conditions are equivalent

(1) \( G/\Gamma \) is algebraic,

(2) \( G/\Gamma \) is projective algebraic,

(3) \( G/\Gamma \) is an abelian variety,

(4) There is a group homomorphism \( \sigma : \Gamma \rightarrow H \) such that

(a) \( q(\gamma, \sigma(\gamma')) = q(\gamma', \sigma(\gamma)) \) for all \( \gamma, \gamma' \in \Gamma \)

(b) \( \langle \gamma, \gamma' \rangle = - \log |q(\gamma, \sigma(\gamma'))| \) is positive definite.

**Proof.** - (3) \( \implies \) (2) \( \implies \) (1) are obvious.

(1) \( \implies \) (4) the transcendence degree of \( \mathbb{M}(G/\Gamma) \) over \( k \) is at least \( n \). Take algebraic independent elts \( f_1, \ldots, f_n \in \mathbb{M}(G/\Gamma) \) and write them as
\[
f_1 = \frac{0}{\theta_0}, \ldots, f_n = \frac{0}{\theta_n}
\]
with \( \text{gcd} (\theta_0, \ldots, \theta_n) = 1 \), \( \theta_0, \ldots, \theta_n \) holomorphic functions. Then \( \theta_0, \ldots, \theta_n \) are theta functions with the same multiplicator \( \mathbb{Z} \).

The algebraic independence of \( f_1, \ldots, f_n \) implies that
\[
\{ \theta_0, \theta_1, \ldots, \theta_n \} \quad \text{satisfying } \sum r_i = \ell
\]
are algebraically independent over \( k \). Hence \( \dim L(\mathbb{Z}^\ell) \geq (\ell^r_n) \). On the other hand,
\[
\dim L(\mathbb{Z}^\ell) = |H/\sigma(\Gamma)|^{\ell} \text{torsion}
\]
where \( \ell = \text{rank } \sigma(\Gamma) \).

Hence \( \text{rank } \sigma(\Gamma) = n \), and we have proved (4).
(2) $\implies$ (3). The multiplicator of $G/\Gamma \subseteq \mathbb{P}^n$: $G/\Gamma \times G/\Gamma \to G/\Gamma$ is an analytic map. By GAGA, it is also an algebraic map.

The hard part is to show (4) $\implies$ (2):

(4.5.1) **Lemma.** Let $Z$ be a cocycle with a positive definite $\sigma$ (as in (4)). Then

1. For every $z \in G$, there exists a $\theta \in L(Z)$ with $\theta(z) \neq 0$.

2. Let $\theta_0, \ldots, \theta_t$ be a base of $L(Z)$. Suppose that $z_1, z_2 \in G$ and $z_1 \neq z_2 \mod \Gamma$. Then the vectors $(\theta_0(z_1), \ldots, \theta_t(z_1))$ and $(\theta_0(z_2), \ldots, \theta_t(z_2))$ in $k^t$ are linearly independent over $k$.

**Proof.**

1. For $\theta \in L(Z)$ and $a, b \in G$ the functions

$$\theta_3 = \theta(z^{-1})\, \theta(z \, b^{-1})\, \theta(zab)$$

belong to $L(Z)$. Let $\theta \neq 0$, then the zero set $X$ of $\theta$ in $G$ has codimension 1. One can find $a, b$ with $a^{-1}, b^{-1}$, $ab \neq z^{-1} X$. Hence $\theta(z) \neq 0$.

2. Suppose that the vectors $(\theta_0(z_1), \ldots, \theta_t(z_1))$ and $(\theta_0(z_2), \ldots, \theta_t(z_2))$ are linearly dependent over $k$. For any $F \in L(Z)$ one has for any $z, b \in G$ and a fixed constant $c \in k^*$:

$$F(z_1, z_1^{-1}) F(z_1, zb) = c F(z_2, z_2^{-1}) F(z_2, b^{-1}) F(z_2, zb).$$

Hence the meromorphic function (of $z$) $F(z_1, zz^{-1})/F(z_2, zz^{-1})$ has no zeros and no poles. So

$$\frac{F(z_1, z_1^{-1})}{F(z_2, z_2^{-1})} \in A = O^*(G).$$

That means $F(z_\nu) = a(z) F(z)$ with $\nu = z_1^{-1} z_2$ and $a \in A$. The explicit formula for the $F_\nu$s in $L(Z)$ given in (4.4.3) implies $\nu \in \Gamma$.

(4.5.2) **Lemma.** Let $Z$ be a positive definite 1-cocycle and let $\theta_0, \ldots, \theta_t$ be a base of $L(Z)$. The holomorphic map $\varphi: G/\Gamma \to \mathbb{P}^t(k)$ given by

$$\varphi(z) = [\theta_0(z), \ldots, \theta_t(z)]$$

has the properties

1. $X = \text{im}(\varphi)$ is an algebraic subspace of $\mathbb{P}^t(k)$ of dimension $n$.

2. $\varphi: G/\Gamma \to X$ is an isomorphism of holomorphic spaces.

**Proof.**

1. $\varphi: G/\Gamma \to \mathbb{P}^t(k)$ is well defined and injective according to (4.5.1) part (1) and (2). Since $G/\Gamma$ is "compact", the map $\varphi$ is proper. By the proper mapping theorem, $X = \text{im}(\varphi)$ is a closed analytic subset of $\mathbb{P}^t(k)$.
By GAGA, \( X = \text{im} (\varphi) \) is also an algebraically closed subset of \( \mathbb{P}_k \). Since \( \varphi: G/T \to X \) is bijective, we have
\[
n = \dim G/T = \dim X + \dim (\text{fibre}) \quad \text{and} \quad \dim (\text{fibre}) = 0.
\]

(2) A covering \( Y_i = \{ a_0, a_1, \ldots, a_t \} \in \mathbb{P}_k \) is given by
\[
Y_i = \{ [a_0, a_1, \ldots, a_t] \in \mathbb{P}_k : |a_j| \leq |a_i| \text{ for all } j \} = \{ (\lambda_1, \ldots, \lambda_t) \in k^t : \text{all } |\lambda_j| \leq 1 \}.
\]

Put \( X_i = Y_i \cap X \); then \( (X_i) \in \text{Cov}(X) \), and one can verify that
\[
(\varphi^{-1}(X_i))_{i=0}^t \in \text{Cov}(G/T).
\]

The map \( \varphi_i: \varphi^{-1}(X_i) \to X_i \) is bijective, and after a calculation of derivatives and finds, for every \( x \in X_i \),
\[
\widehat{\varphi}_{X_i,x} \to \widehat{\varphi}_{G/T, \varphi^{-1}(x)}.
\]

By methods of the type, explained in (2.10), it follows that \( \varphi_i^{-1}: X_i \to \varphi^{-1}(X_i) \) is also holomorphic. Hence \( \varphi: G/T \to X \) has an holomorphic inverse.

(4.6) Final remarks.- Now every abelian variety over \( \mathbb{Q}_p \) can be obtained as a holomorphic torus \( G/T \). One can only parametrize those abelian varieties by a \( G/T \), which degenerate over the residue field \( \mathbb{F}_p \) of \( \mathbb{Q}_p \).

In particular, only those elliptic curves over \( k \) can be parametrized which split into projective lines over the residue field of \( k \) (Equivalently, the \( j \)-invariant has absolute value \( > 1 \)). (See [15]). In [12], D. MUMFORD has shown that also degenerating curves of genus \( g > 1 \), over a local field, have a nice non-archimedean representation.
