Algebraic definition of a functional programming language and its semantic models

RAIRO. Informatique théorique, tome 17, no 2 (1983), p. 137-161

<http://www.numdam.org/item?id=ITA_1983__17_2_137_0>
Abstract. — In the usual framework of abstract types programming languages including a
definition mechanism for partial recursive functions cannot be specified sufficiently complete because
of the termination problem. Therefore the algebraic concepts of abstract types are extended to partial
algebras leading to "total" homomorphisms for partial algebras. In this framework an abstract type
given defining a functional programming language. The category of models of that type can be
structured with the help of a partial order induced by the total homomorphisms. This order shows
the relationship between the different semantic models and the well-known notions of fixed point
theory. Initial and weakly terminal models correspond directly to least fixed points, the subcategories
of optimal and maximal models correspond to optimal and maximal fixed points. Finally, strong
terminality and initiality of the subcategory of minimally defined models can be connected to
mathematical and operational equivalence of recursive functions.

Résumé. — En raison du problème de terminaison la notion usuelle des types abstraits ne permet
pas de spécifier (d'une manière suffisamment complète) des fonctions partiellement récursives ayant
un domaine non récursif. De ce fait nous élargissons les concepts algébriques des types abstraits par
la notion d'algèbre partielle et la notion d'homomorphisme entre algèbres partielles. Nous appliquons
cette méthode de spécification à l'exemple d'un langage de programmation fonctionnelle. La
catégorie des modèles de ce type peut être analysée et structurée à l'aide d'un ordre partiel induit par
les homomorphismes faibles. Cet ordre montre les relations entre les différents modèles sémantiques
d'un type et les notions bien connues de la théorie des points fixes. Les modèles initiaux et faiblement
termiaux correspondent exactement aux plus petits points fixes et les sous-catégories des modèles
optimaux et maximaux correspondent aux points fixes optimaux et aux points fixes maximaux. En
plus les modèles terminaux de la sous-catégorie des modèles minimalement définis décrivent
l'équivalence mathématique entre fonctions récursives pendant que les modèles initiaux de cette
sous-catégorie caractérisent une équivalence opérationnelle.

1. INTRODUCTION

Abstract data types are a uniform, powerful tool for formal specifications. The meaning of such types is generally explained by particular models such as initial or terminal ones, or by the class of all possible models, which may be described by sets of congruences on the term algebra (cf. Wirsing, Broy [34],
Broy et al. [13]).

Of course it would be of interest to use the tool of abstract types to specify the semantics of recursive functions being part of functional programming languages thus considering programs as abstract objects of such a type. Unfortunately in the framework of "equationally definable classes" the termination problem of partial recursive functions can not be specified "sufficiently complete", since it is recursively unsolvable.

In particular using only equations as axioms it is impossible to specify sufficiently complete abstract types including models containing partial recursive functions with non-recursive domains. Therefore such types cannot have terminal nor initial models (cf. Broy, Wirsing [9]).

To cope with these problems we have to extend the notion and theory of abstract data types. Abstract data types consist of sorts and function symbols — called signature — and of equations. The function symbols generate an algebra of terms, called term algebra. On this term algebra the equations induce congruence relations which may be described by homomorphisms. The homomorphisms induce a lattice structure, a complete partial ordering or at least a partial ordering on the classes of isomorphic structures.

There were numerous efforts to extend the abstract type approach to describe types with models containing functions with nonrecursive domains (cf. Wand [32], "rational theories" in ADJ [31] and "algebraic semantics" in Courcelle, Nivat [16]).

These approaches study either least fixed points by assuming continuous interpretations (which is equivalent to the implicit introduction of existential quantifiers) or they consider infinite terms or nonstandard objects (thus extending the carrier set of data which may cause difficulties with structural induction).

In place of that we propose two other extensions of the basic theory:
— an "algebraic" one using partial algebras and homomorphisms for partial algebras instead of total ones;
— a "logical" one using explicitly existential quantifiers in the axioms (cf. Broy et al. [7]).

In section 2.1 we give the basic notions for the theory of partial algebras. In section 2.2 we discuss partial abstract types, that are classes of partial algebras, and prove characterization and existence theorems for initial and weakly terminal algebras of partial abstract types.

As an important application we define an abstract type MAP in section 3.1. The type MAP describes a functional programming language including an evaluation operator for functional programs, i.e. applications of partial recursive functions.
MAP is not and cannot be sufficiently complete but it is “weakly” sufficiently complete.

The weakly terminal models of MAP accord to least fixed point semantics with the mathematical equality between the functionals. Each model of type MAP can be viewed as a particular semantics of the functional programming language. Two semantic models $S_1$ and $S_2$ of MAP can be defined to be extensionally equivalent, if there is a model $M$ of type MAP, such that there are (strong) homomorphisms from both $S_1$ and $S_2$ to $M$. Consequently for a programming language all semantic models are extensionally equivalent, if and only if there exists a strongly terminal model for the corresponding type.

If we consider the class $C_M$ of all models being extensionally equivalent to a given model $M$, then for every model $A$ in $C_M$ the interpretation of a functional $f$ in $A$ yields the same fixed point of $f$ as the interpretation of $f$ in $M$. $C_M$ forms a lattice (cf. Wirsing, Broy [34]). In particular, for every initial model $I$ the class $C_I$ contains all models which describe least fixed point semantics.

With the help of existential quantifiers we can restrict the type MAP to a type MAP' such that $C_I$ represents the class of finitely generated models of MAP'. On the other hand, by introducing a specific approximation function for recursively defined objects of sort map we can restrict MAP to a type MAP* such that the weakly terminal models $Z^*$ of MAP* correspond directly to a notion of operational equivalence while the weakly terminal models $Z$ of MAP correspond to mathematical (functional) equivalence. This leads to a proper formal definition of the different notions of equivalence of recursively defined functions.

2. BASIC DEFINITIONS AND RESULTS

2.1. Partial $\Sigma$-Algebras

We give briefly the basic notions concerning partial heterogeneous algebras and their connection to abstract data types:

A partial heterogeneous algebra $A$ is a pair ($\{s^A\}_{s \in S}$, $\{f^A\}_{f \in F}$) of families where the (countable) index sets $S$ and $F$ are called sorts and functions symbols and where

- $\{s^A\}_{s \in S}$ is a family of carrier sets;
- $\{f^A\}_{f \in F}$ is a family of partial operations on the carrier sets, i.e. for every $f \in F$ the function $f^A$ is a partial mapping $f^A : s_1^A \times \ldots \times s_n^A \rightarrow s_{n+1}^A$ with some $n \in N$, $s_1$, $s_2$, $s_{n+1} \in S$.
$s_1^A \times \ldots \times s_n^A$ is called domain of $f^A$, $s_{n+1}^A$ is called range of $f^A$ and $s_1 \times \ldots \times s_n \rightarrow s_{n+1}$ is called functionality of $f$. If $n = 0$ then $f$ is called constant.

The pair of index sets $\Sigma = (S, F)$ is called signature. $A$ then is called $\Sigma$-algebra and we abbreviate $\{ s^A \}_{s \in S}$ by $S^A$ and $\{ f^A \}_{f \in F}$ by $F^A$.

A $\Sigma$-algebra $A'$ is called $\Sigma$-subalgebra of a $\Sigma$-algebra $A$, if for all $s \in S : s^A \subseteq s^{A'}$ and for all $f \in F : f^A'$ is the restriction of $f^A$ to $A'$ and if $A'$ is closed under all the operations of $A$. For every $\Sigma$-algebra $A$ there exists a smallest $\Sigma$-subalgebra $A_{\text{Gen}}$ of $A$ (with respect to set inclusion). $A_{\text{Gen}}$ is the subalgebra of $A$ finitely generated by the constants and function symbols named in $\Sigma$. $A$ is called finitely generated (or $\Sigma$-structure) if $A_{\text{Gen}} = A$.

From the function symbols itself we obtain particular $\Sigma$-algebras: Let $x_1, \ldots, x_k$ be (free) variables of sort $s_1, \ldots, s_k \in S$. Then $W_\Sigma(x_1, \ldots, x_k)$ is the least set (with respect to set inclusion) $M$ such that $x_1, \ldots, x_k$ and every constant $f \in F$ belong to the appropriate carrier sets of $M$ and, whenever $f : s_1 \times \ldots \times s_n \rightarrow s_{n+1} \in F$ and $t_1, \ldots, t_n$ of sort $s_1, \ldots, s_n$ are in $M$, then $f(t_1, \ldots, t_n)$ belongs to the carrier set $s_{n+1}^M$ of $M$. The elements of $W_\Sigma(x_1, \ldots, x_k)$ are called terms. $W_\Sigma(x_1, \ldots, x_k)$ is made into a $\Sigma$-algebra by defining:

$$f^{W_\Sigma}(t_1, \ldots, t_n) = f(t_1, \ldots, t_n) \quad \text{for} \quad t_i \in s_i^{W_\Sigma}.$$ 

This algebra is a total algebra. We denote it also by $W_\Sigma(x_1, \ldots, x_k)$. If $k = 0$ we write $W_\Sigma$ and call it the term algebra of $\Sigma$. Clearly, $W_\Sigma$ is finitely generated and $\Sigma$-subalgebra of all $W_\Sigma(x_1, \ldots, x_k)$. The elements of $W_\Sigma$ are called ground terms.

For a ground term $t \in W_\Sigma$ and a $\Sigma$-algebra $A$ the interpretation $t^A$ of $t$ in $A$ is obtained by substituting all symbols $f$ in $t$ by $f^A$. Then either $t^A$ denotes an element of a carrier set of $A$ or $t^A$ is undefined.

Homomorphisms for partial algebras are simply partial operations which satisfy the usual homomorphism-property on the domain of every function in the signature:

Let $A, B$ be partial heterogeneous $\Sigma$-algebras.

A family $\{ \varphi_s : s^A \rightarrow s^B \}_{s \in S}$ of possibly partial operations is called $\Sigma$-homomorphism from $A$ into $B$ (denoted by $\varphi : A \rightarrow B$) iff

for all $f : s_1 \times \ldots \times s_n \rightarrow s \in F$ and all $x_1 \in s_1^A, \ldots, x_n \in s_n^A$:

$$f^A(x_1, \ldots, x_n) \text{ defined } \Rightarrow \varphi_s(f^A(x_1, \ldots, x_n)) = f^B(\varphi_{s_1}(x_1), \ldots, \varphi_{s_n}(x_n)).$$
Therefore on total algebras this notion of homomorphism coincides with the usual one. We distinguish different kinds of homomorphisms which will be important in the sequel (cf. Grätzer [19], Broy, Wirsing [8] where a slightly different terminology is used).

Total $\Sigma$-homomorphisms are called "$\Sigma$-homomorphisms" by Grätzer and preserve the definedness of terms. In particular, if a $\Sigma$-homomorphism $\varphi : A \to B$ is total, then

\[
\text{for all } f : s_1 \times \ldots \times s_n \to s \in F \text{ and all } x_1 \in s_1^A, \ldots, x_n \in s_n^A:
\]

\[
f^A(x_1, \ldots, x_n) \text{ defined } \Rightarrow f^B(\varphi_{s_1}(x_1), \ldots, \varphi_{s_n}(x_n)) \text{ defined.}
\]

A total $\Sigma$-homomorphism satisfying also the converse condition is called strong. A $\Sigma$-homomorphism $\varphi : A \to B$ is said to be strong, if it is total and

\[
\text{for all } f : s_1 \times \ldots \times s_n \to s \in F \text{ and } x_1 \in s_1^A, \ldots, x_n \in s_n^A:
\]

\[
f^B(\varphi_{s_1}(x_1), \ldots, \varphi_{s_n}(x_n)) \text{ defined } \Rightarrow f^A(x_1, \ldots, x_n) \text{ defined.}
\]

**Proposition 1:** Let $\varphi : A \to B$ be a $\Sigma$-homomorphism between two $\Sigma$-structures $A$ and $B$.

1. $\varphi$ is total iff for all terms $t \in W_\Sigma$ such that $t^A$ is defined $t^B$ is defined as well and $\varphi(t^A) = t^B$;

2. $\varphi$ is strong iff for all terms $t \in W_\Sigma$ ($t^A$ is defined $\iff$ $t^B$ is defined) and $\varphi(t^A) = t^B$.

**Proof:** (1) $\varphi$ total implies that

\[
f^A(x_1, \ldots, x_n) \text{ defined } \Rightarrow \varphi_s(f^A(x_1, \ldots, x_n)) = f^B(\varphi_{s_1}(x_1), \ldots, \varphi_{s_n}(x_n)) \text{ defined}
\]

holds for all $f : s_1 \ldots s_n \to s$ and all $x_1 \in s_1^A, \ldots, x_n \in s_n^A$. A simple induction on the length of terms concludes the proof.

(2) is proven analogously. □

Properties of $\Sigma$-algebras are expressed by formulas. For simplicity we consider only conditional universal-existential formulas, i.e. formulas of the form:

\[
\forall s_1 x_1 \ldots \forall s_k x_k \exists s'_1 y_1 \ldots \exists s'_l y_l, \\
\bigwedge_{1 \leq i \leq m} [D(p_i) \land p_i = q_i] \Rightarrow C,
\]

vol. 17, n° 2, 1983
where \( k, l, m \geq 0 \) and \( C \) is of the form \( D(t), \neg D(t) \) or \( t = t' \). If \( D(p_i) \) can be inferred from \( p_i = q_i \) then it will be omitted.

A formula without free identifiers is called sentence. The interpretation of a formula in a \( \Sigma \)-algebra is defined as usual in a classical two-valued first-order logic. Truth of \( G \) in \( A \) is denoted by \( A \vDash G \). In particular for ground terms \( t_1, t_2 \) we have \( A \vDash D(t_1) \) iff \( t_1 \) is defined, and \( A \vDash t_1 = t_2 \) iff \( t_1 \) and \( t_2 \) are of the same sort and both undefined in \( A \) or \( t_1 \) and \( t_2 \) are both defined and \( t_1 = t_2 \). Furthermore, \( A \vDash \forall x : G \iff \forall a \in s^d A \vDash G[a/x] \).

The only predicate symbols occurring in formulas are the definedness predicate \( D \) and the identity symbol. Since we are working with heterogenous algebras this is not an essential restriction: A predicate \( p : s_1 \times \ldots \times s_n \to \text{bool} \) where \( \text{bool} \) denotes the sort \( \{\text{true, false}\} \) of the truth-values. Note, however, that there is a difference concerning the notions of homomorphisms between boolean functions and predicates (cf. Chang, Keisler [15]).

Due to the strong interpretation of \( \langle \rangle \), \( t_1 = t_2 \) is always defined and the axioms and rules of inference for classical first order logic (see e.g. Chang, Keisler [15]) as well as a structural induction (cf. Guttag [20]) can be generalized to types (cf. Wirsing, et al. [33]). Because of our approach of partial algebras all functions \( f : s_1 \times \ldots \times s_n \to s_{n+1} \) are strict: For all terms \( t_1, \ldots, t_n \) of sort \( s_1, \ldots, s_n \) the following axiom holds:

\[
D(f(t_1, \ldots, t_n)) \Rightarrow D(t_i) \quad \text{for} \quad i = 1, \ldots, n.
\]

Moreover the following "undefined element axiom" holds:

\[
\neg D(t_1) \land \neg D(t_2) \Rightarrow t_1 = t_2.
\]

2.2. Classes of \( \Sigma \)-structures and Abstract Types

An abstract type \( T = (\Sigma, E) \) consists of a signature \( \Sigma \) and a (countable) set \( E \) of sentences, called axioms. A subtype \( (\Sigma', E') \) with \( \Sigma' \subseteq \Sigma \), \( E' \subseteq E \) may be designated as primitive. Then \( T = (\Sigma, E, (\Sigma', E')) \) is called a hierarchical type, cf. Wirsing et al. [33]. This definition can easily be generalized to several primitive subtypes \( P_1, \ldots, P_n \) and to hierarchical subtypes. For simplicity, however, we consider in the following only types \( (\Sigma, E, P) \) with a nonhierarchical primitive subtype \( P = (\Sigma', E') \); all definitions and properties carry easily over in the general case (cf. also Wirsing et al. [33]).

Moreover, we assume in the following that \( \Sigma' \) contains the sort \text{bool} of truth-values and the constants true, false of sort \text{bool}.

Let \( T = (\Sigma, E, P) \) with \( P = (\Sigma', E') \) be a hierarchical type. A term \( t \in W_\Sigma(x_1, \ldots, x_n) \) is called primitive. If \( t \models f(t_1, \ldots, t_n) \) where
A FUNCTIONAL PROGRAMMING LANGUAGE 143

$\mathbf{f} : s_1 \times \ldots \times s_n \rightarrow s'$ and $s' \in S'$, then $t$ is called of primitive sort. The only primitive terms of sort bool are assumed to be "true" and "false".

If $T$ is hierarchical and $P$ is the primitive type of $T$, then a $\Sigma$-algebra $A$ is called (fg-model) of type $T$, if $A$ is finitely generated, $A \models G$ for all $G \in E$ and the restriction of $A$ to the carrier sets of $P$ satisfies true $\neq$ false and is a fg-model of $P$; i.e. these carrier sets must be finitely generable by primitive functions only.

The class of all $fg$-models of a type $T$ is denoted by $Gen_T$. If $E = \emptyset$ we write $Gen_\Sigma$ for $Gen_{\Sigma, \emptyset}$. We say that a sentence $G$ is $fg$-valid in $T$ ($T \models G$) if for all $A \in Gen_T : A \models G$. $T$ is $fg$-satisfiable if $Gen_T \neq \emptyset$ and $T$ is called monomorphic if all elements of $Gen_T$ are isomorphic.

We call a formula $G$ provable in $T$ ($T \models G$) if $G$ can be deduced from the axioms of $T$ and from the logical axioms and rules including induction. The provability implies $fg$-validity. But the completeness theorem of first-order logic does not hold for all types. If we consider, for instance, a type NAT of natural numbers (cf. ADJ [18]) with addition and multiplication then due to the restriction to finitely generated models Gödel's incompleteness theorem applies to NAT i.e. there exists a sentence $\forall \text{nat } x : G$ such that:

- for all natural numbers $n$ $G[n/x]$ is provable;
- $\forall \text{nat } x : G$ is $fg$-valid, but not provable.

Let $C$ be a class of $\Sigma$-structures. A $\Sigma$-structure $A$ of $C$ is called strongly terminal in $C$, iff for all $\Sigma$-structures $B$ of type $T$ there is a strong homomorphism $\phi : B \rightarrow A$.

$A$ is called initial (strongly initial resp.) in $C$ if for all $B \in C$ there exists a unique total (strong resp.) $\Sigma$-homomorphism $\phi : A \rightarrow B$.

In fixed point theory the semantics of a recursive definition is determined by the least fixed point fulfilling the recursive equation. According to this one class of models is of particular interest: For a class $C$ of $\Sigma$-algebras the class $Mdef(C)$ of minimally defined models is given by:

$$Mdef(C) = \{ A \in C : \forall t \in W_\Sigma : A \models D(t) \Leftrightarrow C \models D(t) \}.$$  

A $\Sigma$-algebra $Z$ in a class $C$ of $\Sigma$-algebras is called weakly terminal in $C$ if it is strongly terminal in $Mdef(C)$.

An algebra $A \in Gen_T$ is called initial in $T$ if it is initial in $Gen_T$, and weakly terminal, if it is strongly terminal in $Mdef(Gen_T)$.

vol. 17, n° 2, 1983
Analogously $A$ is called strongly initial and strongly terminal resp. if it is so in $\text{Gen}_r$. Initial and weakly terminal algebras can be characterized as follows:

**Proposition 2:** Let $A$ be a model of $T$. Then:

(a) $A$ is initial in $T$ iff:

1. $A$ is minimally defined, i.e., for all $t \in W_\Sigma : A \vdash D(t) \iff T \vdash D(t)$ and
2. for all $t$, $t' \in W_\Sigma$ of the same sort:

$$A \vdash t' = t \iff (T^* \not\vdash D(t) \text{ and } T^* \vdash D(t')) \text{ or } T \not\vdash t' = t.$$ 

(b) Let the primitive type $P$ of $T$ be monomorphic and the terms $p_0$, $q_i$ in the antecedences of the axioms be of primitive sort. Then $A$ is weakly terminal in $T$ iff:

1. $A$ is minimally defined, i.e.:
   for all $t \in W_\Sigma : A \vdash D(t) \iff T \vdash D(t)$ and
2. for all $t$, $t' \in W_\Sigma$ of the same sort:

$$A \vdash t = t' \iff \forall K(x) \in W(\Sigma, x) \text{ of primitive sort:}$$

$$A \vdash K[t/x] = K[t'/x].$$

**Proof:** Proposition 1 and 2 of Broy, Wirsing [11].

In order to prove the existence of initial and weakly terminal algebras we define two further notions:

A type $T$ is called weakly sufficiently complete iff for every ground term $t$ of primitive sort such that $D(t)$ is provable there exists a primitive term $p$ such that $t = p$ is provable. If either $\not\vdash D(t)$ is provable or such a primitive term $p$ exists, then $T$ is called sufficiently complete.

An axiom $\forall s_1 x_1 \ldots \forall s_k x_k \exists s'_1 y_1 \ldots \exists s'_l y_l : G$ where $G$ is quantifier-free is called uniform in $T$, if for all ground terms $t_1, \ldots, t_k$ such that $D(t_1), \ldots, D(t_k)$ is provable there exist ground terms $t'_1, \ldots, t'_i$ such that:

$$D(t'_1) \land \ldots \land D(t'_i) \land G[t_1/x_1, \ldots, t_n/x_n, t'_1/y_1, \ldots, t'_i/y_i]$$

is valid in $T$.

**Theorem 1:** Let $T$ be a satisfiable, weakly sufficiently complete type the primitive subtype of which is monomorphic.

If all nonprimitive axioms of $T$ are uniform with antecedences $p_i$, $q_i$ of primitive sort, then $T$ has an initial and a weakly terminal algebra.

R.A.I.R.O. Informatique théorique/Theoretical Informatics
Proof: For axioms without existential quantifiers apply corollaries 1 and 4 of Broy, Wirsing [11]. The case of axioms with existential quantifiers reduces to the one without existential quantifiers since the uniformity implies that every axiom containing existential quantifiers can be replaced by (infinitely many) axioms without existential quantifiers. □

3. APPLICATIONS

A programming language can be described by an abstract type in the following way:

- The context-free syntax corresponds to the term algebra of the type's signature. The sorts denote the syntactic entities.
- The context-conditions correspond to particular definedness predicates specifying that certain terms are not defined.
- The semantics of the language is given by the equational axioms.

In the following we design a simple functional programming language as a hierarchical type. Starting with a basic "primitive" data type (including \texttt{bool, nat}, etc.) we define a type MAP containing (besides the sorts of the basic type) a sort \texttt{map(ping)} the terms of which represent the programs of a functional programming language (cf. Backus [1]).

3.1. The type MAP

As primitive sorts for the data type MAP we use a sort \texttt{data} and a sort \texttt{id} of identifiers (for functions). For simplicity we assume that \texttt{data} comprises the sort \texttt{bool} of the truth-values "true" and "false". In analogy to the classical theory of recursive functions (cf. Shoenfield [30]), we define recursive functions relatively to a given family \( \{ f_i \}_{i \in I} \) of primitive functions on \texttt{data}. For simplicity we assume, that the sorts \texttt{id} and \texttt{data} and the functions \( \{ f_i \}_{i \in I} \) are specified by some monomorphic types \texttt{ID} and \texttt{DATA}, i.e. by types having only isomorphic models.

The terms (objects) of sort \texttt{map} are functions constructed from the primitive functions \( \{ f_i \}_{i \in I} \), selector functions \( s_j \), and the functionals fcond for conditionals, comp for functional composition and def for the recursive definition of functions. As in Backus [1] no formal arguments are needed. For
every "functional program" \( f \), i.e. for every term \( f \) of sort \( \text{map} \), an apply-operation defines the application of \( f \) to a tuple of objects of sort \( \text{data} \). The laws (A1)-(A6) for apply simply describe the behavior of a (call-by-value-) text substitution machine.

The function \( \text{sub} \) is used as an auxiliary (hidden) function, where \( \text{sub}(i, f, g) \) replaces all free occurrences of \( i \) in \( f \) by \( g \). The equations (S) for \( \text{sub} \) are the usual ones known from the substitution operation in the \( \lambda \)-calculus.

The function \( \text{occurs} \) is used as a "syntactic" auxiliary (hidden) function for formulating the axioms of local renaming (\( \alpha \)-reduction).

type MAP =
primitives: ID, DATA,
sort: \( \text{map} \),
functions:
\[
\begin{align*}
\text{map } f_i, & \quad \text{for the primitive functions } f_i \in F_{\text{DATA}}, \ i \in I \\
\text{map } s_j, & \quad \text{selector function } j \in \mathbb{N} \setminus \{0\} \\
(id) \text{ map } \text{fid}, & \quad \text{interpretation of identifiers as functions} \\
(id, map) \text{ map } \text{def}, & \quad \text{(recursive) function declaration} \\
(map, map, map) \text{ map } \text{fcond}, & \quad \text{conditional functional} \\
(map, \ldots, map) \text{ map } \text{comp}, & \quad \text{composition of functions} \\
(id, map, map) \text{ map } \text{sub}, & \quad \text{substitution operator} \\
(map, data, \ldots, data) \text{ data } \text{apply}, & \quad \text{apply-operator} \\
(id, map) \text{ bool } \text{occurs}, & \quad \text{free occurrence of identifiers},
\end{align*}
\]

\[
(S) \begin{cases}
\text{occurs } (i, f_i) = \text{false}, \\
\text{occurs } (i, s_j) = \text{false}, \\
\text{occurs } (i, \text{fid}(j)) = (i = j), \\

A FUNCTIONAL PROGRAMMING LANGUAGE

147

(A2) apply \((s_j, d_1, \ldots, d_n) = \begin{cases} d_j & \text{if } 1 \leq j \leq n \\ \text{error} & \text{otherwise} \end{cases}\)

(A3) apply \((\text{id}(i), d_1, \ldots, d_n) = \text{error}\)

(A4) apply \((\text{def}(i, g), d_1, \ldots, d_n) = \text{apply}(\text{sub}(i, g, \text{def}(i, g)), d_1, \ldots, d_n)\)

(A5) apply \((p, d_1, \ldots, d_n) = \text{true} \implies \text{apply}(\text{fcond}(p, g, h), d_1, \ldots, d_n) = \text{apply}(g, d_1, \ldots, d_n)\)

(A5a) apply \((p, d_1, \ldots, d_n) = \text{false} \implies \text{apply}(\text{fcond}(p, g, h), d_1, \ldots, d_n) = \text{apply}(h, d_1, \ldots, d_n)\)

(A5c) apply \((p, d_1, \ldots, d_n) \neq \text{true} \land \text{apply}(p, d_1, \ldots, d_n) \neq \text{false} \implies \text{apply}(\text{fcond}(p, g, h), d_1, \ldots, d_n) = \text{error}\)

(A6) apply \((\text{comp}(g_{o1}, \ldots, g_{on}), d_1, \ldots, d_n) = \text{apply}(g_{o1}, \text{apply}(g_{o2}, d_1, \ldots, d_n), \ldots, \text{apply}(g_{on}, d_1, \ldots, d_n))\)

Note that for a nullary primitive function \(f\), apply \((\text{comp}(f')) = \text{apply}(f')\)

(end of type)

The function occurs is specified sufficiently completely. Every term occurs \((i, x)\) can be reduced either to true or to false, i.e. occurs is a total function in every structure of type \(\text{MAP}\).

The equation \(t = \text{error}\) is an abbreviation for \(\neg D(t)\) and indicates, that the interpretation of the term \(t\) is undefined in every model. For the sake of simplicity we omit subscripts in the function (scheme)'s \text{comp} and \text{apply} (giving the number of parameters) and give the respective conditions for well-formedness (the context conditions) only verbally.

Based on a suitable abstract type for natural numbers the factorial function can be specified as follows:

\[
def(\text{fac}, \text{fcond}(\text{eq0}', \text{1}', \text{comp}(\text{*}', \text{s1}', \text{comp}(\text{fid}(\text{fac}), -1'))))
\]

where \(\text{eq0}\) denotes the test for zero and \(-1\) the predecessor operation.

Note that we did not introduce an explicit tupling operator like:

\[
(\text{map}, \ldots, \text{map}) \text{map}[\ldots, \ldots, .]
\]

as a constructor function to generate objects of sort \(\text{map}\) with tuples of sort \(\text{data}\) as results (cf. [1]).

Of course such a tupling operator with:

\[
\text{apply}([g_1, \ldots, g_k], d_1, \ldots, d_n) =
\text{apply}(g_1, d_1, \ldots, d_n) \& \ldots \& \text{apply}(g_k, d_1, \ldots, d_n)
\]

could well be specified if the range of the \text{apply} operation is extended to sequences ("\&" denotes the concatenation of sequences). The resp. axioms for

vol. 17, nº 2, 1983
occurs, sub and fcond are obvious. We tried to avoid to do so because we did not want to introduce any additional structure on the domains and ranges.

In fact the tupling-operator is implicitly contained in our particular composition operator, which actually is a specific combination of the composition operator \("."\) (for binary functions) and the tupling operator:

\[
\text{comp}(g_0, \ldots, g_k) = [g_1, \ldots, g_k] \cdot g_0.
\]

In fact, a slightly syntactically sugared version of the abstract syntax given by the signature of type MAP could be taken as a small functional programming language:

\[
\begin{align*}
\text{Denote} \\
\text{fid}(i) & \quad \text{by } i \\
\text{fcond}(p, g, h) & \quad \text{by } \text{if } p \rightarrow g, h \text{fi} \\
\text{comp}(g_0, g_1) & \quad \text{by } g_1 \cdot g_0 \\
\text{comp}(g_0, g_1, \ldots, g_n) & \quad \text{by } [g_1, \ldots, g_n] \cdot g_0 \quad \text{for } n \geq 2 \\
\text{def}(i, g) & \quad \text{by } i : : g
\end{align*}
\]

Example:

(1) Factorial Function:

\[
\text{fac} : : \text{ifeq}^0 \rightarrow 1', [s_1, -1'.\text{fac}] \ast ' \text{fi}
\]

(2) Ackermann Function:

\[
\text{ack} : : \text{if} s_1 . \text{eq}^0 \rightarrow s_2 . + 1', \\
\text{if} s_2 . \text{eq}^0 \rightarrow [s_1 . -1', 1'].\text{ack}, \\
\quad [s_1 . -1', [s_1, s_1 . -1'].\text{ack}] . \text{ack} \\
\text{fi}
\]

As can be seen immediately, using the axioms (S), every term \(t\) of sort MAP containing the substitution operator sub can be reduced to a term not containing sub. The function sub is only used as an auxiliary function for defining the axioms for the function apply.

Due to the strictness of the operations each term \(t\) of sort MAP must be defined in all models (which follows from the definition of occurs, since occurs is total).

Furthermore, for all terms \(t\) of sort MAP the term apply \((t, d_1, \ldots, d_n)\) can be reduced by the rules in (A) and (S) resp. But not every reduction yields a unique or defined result.
For example if \( f \) is the (trivial) recursive definition \( \text{def}(g, \text{fid}(g)) \) we obtain

\[
\begin{align*}
\text{apply}(\text{def}(g, \text{fid}(g)), d_1, \ldots, d_n) &= \\
\text{apply}((\text{sub}(g, \text{fid}(g)), \text{def}(g, \text{fid}(g))), d_1, \ldots, d_n) &= \\
\text{apply}(\text{def}(g, \text{fid}(g)), d_1, \ldots, d_n).
\end{align*}
\]

Since no other axioms are applicable to these terms, the value of them is not fixed in MAP. For every primitive term \( d \) of sort \text{data} there exists a \( fg \)-model \( A_d \) of MAP with \( \text{apply}(\text{def}(g, \text{fid}(g)), d_1, \ldots, d_n) = d \) in \( A_d \). Thus suppose MAP has a strongly initial model. Then in any such model of MAP \( \text{apply}(\text{def}(g, \text{fid}(g)), d_1, \ldots, d_n) \) must be different from any primitive term \( d \) of sort \text{data}. Analogously in any strongly terminal \( fg \)-model it would be equal to any \( d \), i.e. \text{data} \ could contain at most one element. Consequently MAP cannot have any strongly terminal \( fg \)-model and MAP cannot have any strongly initial \( fg \)-model which is a persistent enrichment (cf. ADJ [18]) of (initial or terminal) \( fg \)-models of DATA. MAP is neither sufficiently complete nor persistent.

### 3.2. Partial initial and weakly terminal models of the type MAP

Now we give two particular models for the type MAP. A term-model \( I \) and a model \( Z \) based on functional abstraction.

The model \( I \) is defined by a quotient structure on the term algebra \( W_{\text{MAP}} \), where \( \equiv_I \) is defined for the terms of sort \text{map} by

\[
t_1 \equiv_I t_2 \text{ iff } \overline{t}_1 = \overline{t}_2 \text{ where } \overline{t}_1 \text{ and } \overline{t}_2 \text{ originate from } t_1 \text{ and } t_2 \text{ resp. by eliminating all occurrences of the function subst and by local renaming of all identifiers such that the local identifiers in } \overline{t}_1 \text{ and } \overline{t}_2 \text{ appear in some fixed linear order, i.e. } \text{MAP} \vdash t_1 = t_2.
\]

According to this definition all functions with range \text{map} \ are simple term-constructor functions apart from the function \text{sub} \, which can always be eliminated. The values of the function \text{occurs} \ are uniquely determined, since \text{occurs} \ is defined sufficiently complete.

So it remains to define the function \text{apply} \,

\[
\text{apply}(f, x_1, \ldots, x_n)
\]

\[
= \begin{cases} 
 y' & \text{if } \exists y \in W_{\text{DATA}} : \text{MAP} \vdash (f, x_1, \ldots, x_n) = y \\
 \text{undefined} & \text{otherwise}
\end{cases}
\]

As is well-known from \( \lambda \)-calculus fully abstract (cf. Milner [25]) models are much harder to define. To avoid the technical details for the introduction of
environment used to cope with terms \( f \) of sort \( \text{map} \) for which some object \( i \) of sort \( \text{id} \) the predicate occurs \((i, f)\) yields true we restrict ourselves to give a semantic representation for "closed" objects of sort \( \text{map} \), i.e. for objects \( f \) such that \( \forall \text{id} i : \text{occurs}(i, f) = \text{false} \). In this case an object \( f \) of sort \( \text{map} \) can be represented by a family of functions \((\text{data}^Z)^n \to \text{data}^Z\), i.e.

\[
f^Z = \{ \lambda x_1, \ldots, x_n : \text{apply}^I(f^I, x_1, \ldots, x_n) \}_{n \in \mathbb{N}}.
\]

With this definition the application of such a semantic object \( f^Z \) to \( n \) arguments of sort \( \text{data}^Z \) is simply defined by applying the \( n \)-ary function form the family \( f^Z \) to the arguments.

**Proposition 3:** \( I \) and \( Z \) (appropriately extended to "nonclosed" objects) are models of \( \text{MAP} \).

**Proof:** By checking the validity of the axioms of \( \text{MAP} \). \( \square \)

These two models show that the type \( \text{MAP} \) is satisfiable. \( \text{MAP} \) is also weakly sufficiently complete:

**Lemma 1:** The type \( \text{MAP} \) is weakly sufficiently complete.

**Proof:** A simple structural induction shows that the operation \( \text{occurs} \) is sufficiently completely defined.

By changing axiom (A6) into the following essentially equivalent one

\[
\text{(A6') } \text{apply}(g_1, d_1, \ldots, d_n) = y_1 \land \ldots \land \text{apply}(g_m, d_1, \ldots, d_n) = y_m \Rightarrow
\]

\[
\text{apply}(\text{comp}(g_0, \ldots, g_m), d_1, \ldots, d_n) = \text{apply}(g_0, y_1, \ldots, y_m)
\]

all axioms involving \( \text{apply} \) have conclusions of the form:

(i) \( \text{apply}(t) = \text{apply}(t') \) or \( \text{apply}(t) = t' \) or

(ii) \( \text{apply}(t) = \text{error} \)

where \( t \) and \( t' \) do not contain any nonprimitive function symbol with range in a primitive sort. Terms on the left-hand side of (ii) satisfy trivially the weak sufficient completeness whereas for terms on the left-hand side of (i) we can apply corollary 2 of Broy, Wirsing [11].

The sufficient completeness of \( \text{occurs} \) together with the weak sufficient completeness of \( \text{apply} \) yield the weak sufficient completeness of \( \text{MAP} \). \( \square \)

**Theorem 2:** \( \text{MAP} \) has initial and weakly terminal models.

**Proof:** Due to proposition 3 and lemma 1 \( \text{MAP} \) is satisfiable and weakly sufficiently complete. The primitive types \( \text{ID} \) and \( \text{DATA} \) are assumed to be
monomorphic. Every antecedens \( p = q \) of an axiom is of primitive sort and \( D(p) \) can be inferred (since \( q \) is of the form true, false or is a variable). Thus according to theorem 1 in section 2.4 MAP has initial and weakly terminal models.

In particular, \( I \) is an initial and \( Z \) is a weakly terminal model.

**Theorem 3:** \( I \) is an initial and \( Z \) is a weakly terminal model of MAP.

**Proof:** \( I \) and \( Z \) are minimally defined. Thus proposition 2(a) together with the definition of \( I \) implies immediately that \( I \) is an initial model of MAP.

The definition of \( Z \) implies that for closed ground terms \( f \) and \( g \) of sort \( \text{map} \):

\[
Z \vdash f = g \text{ iff } \forall \text{data} x_1, \ldots, x_n : \\
Z \vdash \text{apply}(f, x_1, \ldots, x_n) = \text{apply}(g, x_1, \ldots, x_n).
\]

Hence according to proposition 2(b) the congruence of \( Z \) is coarser than the one of the weakly terminal models. Hence since \( Z \) as well as the weakly terminal models are minimally defined there exists a strong homomorphism from every weakly terminal model onto \( Z \). Then the definition of weak terminality implies that this homomorphism is an isomorphism. Therefore \( Z \) is weakly terminal. \( \square \)

### 3.3. Comparing the models of MAP

In the following let us fix two single models \( ID \) and \( D \) of ID and DATA (as subalgebras) for all models of MAP. This is possible since ID and DATA are assumed to be monomorphic.

Then we can introduce the following quasi-ordering \( \sqsubseteq \) for two models \( A \) and \( B \) of type MAP:

\( A \sqsubseteq B \) (\( A \) is *extensionally weaker* than \( B \)) if for all ground terms \( t \) of primitive sort:

\[
[A \vdash D(t)] \Rightarrow t^A = t^B.
\]

This quasi-ordering induces an equivalence relation \( \sim \):

\( A \sim B \) (\( A \) *extensionally equivalent* to \( B \)) if

\[
A \sqsubseteq B \quad \text{and} \quad B \sqsubseteq A
\]

By \( C_A \) we denote the class of all models \( B \) of MAP with \( B \sim A \).

vol. 17, n° 2, 1983
Note: In Broy, Wirsing [11] and Broy, Pair, Wirsing [13] \(A \vdash D(t) \iff B \vdash D(t)\) for all ground terms \(t\) is also required to have extensional equivalence. This property can be deduced for extensional equivalent models of type MAP since all nonprimitive terms are defined.

**Proposition 4:** The class \(\text{Mdef}(\text{Gen}_{\text{MAP}})\) of all minimally defined algebras of MAP is a class of extensional equivalence. In particular, the initial model \(I\) and the weakly terminal model \(Z\) are extensionally equivalent.

**Proof:** Obvious. □

On the level of terms the quasi-ordering \(\sqsubseteq\) corresponds to the “less defined”-ordering in Manna [23]:

Let \(f\) and \(g\) be two ground terms of sort \(\text{map}\).

\[
\begin{align*}
\text{f}^A \sqsubseteq \text{g}^B \iff & \text{all contexts } K(x) \in W_{\text{MAP}}(x) \text{ of sort } \text{map} \\
& \text{and all } d_1, \ldots, d_n \in W_{\text{DATA}} \\
& [A \vdash D(\text{apply}(K[f/x], d_1, \ldots, d_n))] \\
& \text{apply}(K[f/x], d_1, \ldots, d_n)^A = \text{apply}(K[g/x], d_1, \ldots, d_n)^B
\end{align*}
\]

For closed objects \(f\) and \(g\) of sort \(\text{map}\) this is equivalent to:

\[
\begin{align*}
\text{f}^A \sqsubseteq \text{g}^B \iff & \text{all } d_1, \ldots, d_n \in W_{\text{DATA}}: \\
& [A \vdash D(\text{apply}(f, d_1, \ldots, d_n))] \\
& \text{apply}(f, d_1, \ldots, d_n)^A = \text{apply}(g, d_1, \ldots, d_n)^B.
\end{align*}
\]

Defining \(f^A \sim g^B\) by \(f^A \sqsubseteq g^B \land g^B \sqsubseteq f^A\), we can analyse the classes \(C_A\):

**Proposition 5:**
1. For all \(B, B' \in C_A\) and every closed ground term \(f\) of sort \(\text{map}\) \(f^B \sim f^{B'}\).
2. Every total homomorphism \(\varphi : B \to B'\) for \(B, B' \in C_A\) is strong.

**Proof:** (1) Obvious. (2) For all nonprimitive ground terms \(t \in W_{\text{map}}\) \(MAP \vdash D(t)\). Together with the extensional equivalence of \(B\) and \(B'\) this implies \(B \vdash D(t) \iff B' \vdash D(t)\) for all ground terms \(t\).

Thus according to proposition 1 every homomorphism \(\varphi : B \to B'\) is strong. □

**Theorem 4:** (1) There exists a strongly initial fg-model \(I_A\) in \(C_A\) such that the equality in \(\text{map}\) is nearly the syntactic equality:

\[
I_A \vdash f = g \iff f = g, \text{ where } = \text{ denotes the congruence relation induced by } (S).
\]

R.A.I.R.O. Informatique théorique/Theoretical Informatics
(2) There exists a strongly terminal \( f_g \)-model \( Z_A \) in \( C_A \) such that for all terms \( f, g \) of sort \text{map} without free identifiers:

\[ Z_A \vdash f = g \text{ iff } f^{Z_A} \sim g^{Z_A}. \]

(3) The congruences \( \sim_B \) associated to the elements \( B \in C_A \) form a complete lattice with respect to the following ordering \( \subseteq \):

\[ \sim_B \subseteq \sim_{B'}, \iff \text{there exists a strong homomorphism } \varphi : B' \to B; \]

\[ \sim_{I_A} \text{ is the maximum and } \sim_{Z_A} \text{ the minimum of this lattice.} \]

Proof: (1) If terms \( g \) of sort \text{map} contain no applications of "sub", then no further equivalence is induced by the axioms. For every \( B \) in \( C_A \) and every term \( t \), \( h(t^{l_A}) = t^B \) defines a homomorphism.

(2) The \( \sim \)-equivalence is an equivalence relation on the term algebra of MAP and compatible with the laws of type MAP. Hence the term algebra modulo \( \sim \) is a model of MAP. For every \( B \) in \( C_A \) and every term \( t \), \( h(t^B) = t^{Z_A} \) defines a strong homomorphism.

(3) Theorem 5 of Broy, Pair, Wirsing [13]. □

Corollary: The initial model \( I \) of MAP is strongly initial and the weakly terminal model is strongly terminal in the class \( C_I = C_Z = M_{def}(\text{Gen}_{\text{MAP}}) \). □

Therefore the equality for terms of sort \text{map} in \( I_A \) is decidable (provided the equality between identifiers is decidable), whereas the one in \( Z_A \) is not even recursively enumerable. Due to the termination problem for "apply" no model of MAP will be computable in the sense of Bergstra, Tucker [4]. The strongly terminal \( f_g \)-models of every \( C_A \) provide a fully abstract semantics for MAP in the sense of Milner [25].

The reduction:

\[ \text{def } (i, g) = \text{sub}(i, g, \text{def}(i, g)), \]

holds in the strongly terminal algebras of \( C_A \) but not in the strongly initial ones. To compare the classes \( C_A \) of extensional equivalence we define:

\[ C_A \sqsubseteq C_B \iff \text{ for all } M \in C_A, \exists M' \in C_B : M \sqsubseteq M'. \]

\( C_A \) is \textit{optimal} \( \iff C_A \) is the maximum of all classes \( C_M \) which are

extensionally less defined than all maximal classes i.e.

\[ \forall \text{ maximal } C_B : C_A \sqsubseteq C_B \text{ and } \forall C_M : (\forall \text{ maximal } C_B : C_M \sqsubseteq C_B) \Rightarrow C_M \sqsubseteq C_A. \]
THEOREM 5: The extensional equivalence classes of type MAP form a semilattice w.r.t. $\sqsupseteq$ with an optimal element and where the class $C_Z$ of the weakly terminal model $Z$ of MAP is the least element.

Proof: Analogously to the proof of lemma 1 and theorem 2 one can prove the assumptions of theorem 7 in Broy, Pair, Wirsing [13]. Thus the classes of extensional equivalence form a semilattice. To get an optimal element we have only to take the greatest lower bound of all maximal elements. \qed

3.4. Fixed points and functionals

In analogy to the theory of recursive functions a functional is an element of $W_{\text{MAP}}(x)$ of sort $\text{map}$ where $x$ denotes a variable of sort $\text{map}$.

An object $f^A$ of sort $\text{map}$ is called $A$-fixed point of the functional $\tau[x]$ iff $f^A \sim \tau^A[f^A]$, here $A$ is an arbitrary model of type MAP.

This definition is justified by the following properties:

Lemma 2: (1) $\text{def}(i, g)^A$ is an $A$-fixed point of sub$(g, i, .)$ for every model $A$, i.e. $\text{def}(i, g)^A \sim \text{sub}(i, g, \text{def}(i, g))^A$ by (A4).

(2) If $f^A$ is an $A$-fixed point of sub$(i, g, .)$ then there exists a model $B$ of type MAP such that $f^A \sim \text{def}(i, g)^B$. \qed

According to the definitions of Manna, Shamir [24] we call a fixed point $f^A$ of the functional sub$(i, g, .)$ (where $f$ is a ground term of sort $\text{map}$ and $A$ a model of MAP):

- least fixed point, if for all fixed points $h^B$ of sub$(i, g, .)$: $f^A \sqsubseteq h^B$,
- maximal fixed point, if for all fixed points $h^B$ of sub$(i, g, .)$
  \[ f^A \sqsubseteq h^B \Rightarrow f^A \sim h^B, \]
- optimal fixed point, if for all maximal fixed points $h^B$ of sub$(i, g, .)$
  \[ f^A \sqsubseteq h^B \text{ and for all fixed points } f^C \text{ with } f^C \sqsubseteq h^B \text{ for all maximal fixed points } h^B \text{ we have } f^C \sqsubseteq f^A. \]

Then we obtain the following connection to the ordering on model classes introduced.

Proposition 6: Let $C_{\text{opt}}$ be an optimal and $C_{\text{max}}$ be a maximal class of MAP. Then for every model $L \in C_{\text{gen}(\text{Gen}_{\text{MAP}})}$, $O \in C_{\text{opt}}$ and $M \in C_{\text{max}}$:

(1) $\text{def}(i, g)^L$ is a least fixed point;
(2) $\text{def}(i, g)^O$ is an optimal fixed point;
(3) $\text{def}(i, g)^M$ is a maximal fixed point

of the functional sub$(i, g, .)$. 

R.A.I.R.O. Informatique théorique/Theoretical Informatics
The theorems give us a good impression of the structure of the category of models of type MAP. This structure may be illustrated by the following figure:

Call-by-value, call-by-name

All models $A$ of type MAP correspond to call-by-value semantics, since our functions (especially the selector functions) are assumed to be strict (cf. de Bakker [3], de Roever [28]).

3.5. Provability and computability: operational semantics

So far we have payed much attention to the extensional equivalence. In the category $C_M$ the extensional equivalence corresponds to the equality of the strongly terminal $fg$-models in $C_M$. Now we want to discuss the other $fg$-models in $C_M$. To do this we restrict ourselves to $C_Z$, where $Z$ is a weakly terminal $fg$-model of type MAP. For every $fg$-model $A$ in $C_Z$ and every closed ground term $t$ of sort $\text{map}$ a term $\text{apply}(t, d_1, \ldots, d_n)$ is defined if and only if there is a primitive term $r$ of sort $\text{data}$ such that $\text{apply}(r, d_1, \ldots, d_n) = r$
provable in type MAP. Thus we may equate computability with provability.
For every term.

\((*)\) apply \((t, d_1, \ldots, d_n)\) with primitive terms \(d_1, \ldots, d_n\)
with a ground \(t\) of sort map in which an application of \text{sub} does not occur only
one nonprimitive axiom is applicable. If \text{sub} occurs in \(t\), the laws (S) always
allow to transform \(t\) uniquely (modulo renaming) in an equivalent term \(t'\) such
that \(t = t'\) is provable, where \text{sub} does not occur in \(t'\). If we assume left-to-right
evaluation of apply in the axiom (A6) concerning the function "comp", then
for every term \((*)\) a deduction sequence is uniquely determined. If the
generated sequence is infinite, then \((*)\) is not defined in all models of \(C_Z\).

\(C_Z\) corresponds to least fixed point semantics. The strongly terminal \(fg\-
models\) of \(C_Z\) specify the mathematical equality between two (relatively)
partial recursive functions whereas the strongly initial models \(I_Z\) of \(C_Z\)
correspond to the syntactic equality (cf. the first lemma and the theorem of
the last section II.2), i.e. two programs \(f, g\) of sort map are equal in \(I_Z\) iff they
have the same Gödel-Number (cf. Rogers [29]). Considering the termination
problem for apply we see that every \(fg\)-model in \(C_Z\) is cosemicomputable (cf.
Bergstra, Tucker [4]).

In the strongly initial \(fg\)-model \(I\) in \(C_Z\) the equality of two objects of map
corresponds exactly to operational equivalence, if we consider only terms \(t\)
where no free identifiers occur, i.e. \(\forall \text{id} i : \neg \text{occurs} (i, t)\) holds (programs with
free identifiers are excluded generally by context conditions in the formal
definition of programming languages).

Using axioms with existential quantifiers one can specify a type MAP\(^*\) the
\(fg\)-models of which belong to \(C_Z\). We enrich type MAP by two further
functions:

\[
\begin{align*}
\text{funct} \quad \text{map} \quad \Omega, \\
\text{funct} \quad (\text{id}, \text{map}, \text{nat}) \quad \text{map iter},
\end{align*}
\]

with the laws (here nat denotes the sort of natural numbers):

\[
\begin{align*}
\text{sub} (i, \Omega, x) & = \Omega, \\
\text{occurs} (i, \Omega) & = \text{false}, \\
\text{apply} (\Omega, d_1, \ldots, d_n) & = \text{error}, \\
\text{iter} (i, g, 0) & = \Omega, \\
\text{iter} (i, g, m + 1) & = \text{sub} (i, g, \text{iter} (i, g, m)).
\end{align*}
\]
Then we can define approximations for objects def \((i, g)\) by \(\text{iter}(i, g, n)\) with \(n \in \mathbb{N}\). It is trivial to show that for every model \(A\) of MAP*: 

\[
\text{iter}(i, g, n)^A \subseteq \text{iter}(i, g, n + 1)^A
\]

and that for all \(i, g, m, d_1, \ldots, d_n\) there exists some term \(d \in W_{\text{DATA}} \cup \{\text{error}\}\) such that \(\text{apply}(\text{iter}(i, g, m), d_1, \ldots, d_n) = d\) is provable, provided no further application of def occurs in \(g\).

By adding the axiom (cf. de Bakker [3]):

\[
(\forall \text{nat } m : \text{apply}(\text{iter}(i, g, m), d_1, \ldots, d_n) = \text{error}) \Rightarrow \text{apply}(\text{def}(i, g), d_1, \ldots, d_n) = \text{error}
\]

to type MAP*, the resulting type contains only \(fg\)-models in \(C_Z\) of type MAP.

If all basic functions \(f_i\) of MAP are continuous, then MAP* is consistent and possesses a strongly initial \(fg\)-model, which is a strongly initial \(fg\)-model in \(C_Z\). Furthermore it has a terminal model in which two terms of sort \(\text{map}\) without free identifiers are equal iff they are mathematically (i.e. extensionally) equivalent.

Now we may introduce a function:

\[
\text{funct (map, nat) map approx}
\]

specified by:

\[
\begin{align*}
\text{approx}(f', n) &= f', \\
\text{approx}(s_j, n) &= s_j, \\
\text{approx}(\text{fid}(h), n) &= \text{fid}(h), \\
\text{approx}(\text{fcond}(p, g, h), n) &= \text{fcond}(\text{approx}(p, n), \text{approx}(g, n), \text{approx}(h, n)), \\
\text{approx}(\text{comp}(g_0, \ldots, g_m), n) &= \text{comp}(\text{approx}(g_0, n), \ldots, \text{approx}(g_m, n)), \\
\text{approx}(\text{def}(k, g), 0) &= \Omega, \\
\text{approx}(\text{def}(k, g), n + 1) &= \text{sub}(k, \text{approx}(g, n + 1), \text{approx}(\text{def}(k, g), n)),
\end{align*}
\]

The introduction of approx allows to distinguish extensionally equivalent functions, if they are not "operationally equivalent". Moreover approx defines approximations for "recursively defined" objects of sort map; i.e. we have:

\[
\forall \text{map } f, \text{data } d_1, \ldots, d_n, d, \text{nat } n : \\
\text{apply}(\text{approx}(f, n), d_1, \ldots, d_n) = d \Rightarrow \text{apply}(f, d_1, \ldots, d_n) = d.
\]
Moreover for each term $t$ of sort $\text{map}$ the values of:

$$\text{apply}(\text{approx}(t, n), d_1, \ldots, d_n)$$

are uniquely determined (independently from the particular model of $\text{MAP}$).

In the type $\text{MAP}'$ which is generated by enriching $\text{MAP}$ by the function $\text{approx}$ we again have weakly terminal $f^g$-models, which now characterize some notion of "operational equivalence".

4. CONCLUDING REMARKS

If the meaning of programming languages is to be specified by algebraic theories using first order equations, the fixed point properties can be expressed quite straightforward (cf. also [32]). However, generally it is impossible to specify in first order, that a function has to be the least (defined) fixed point of a functional, since this is a second order property. If the concept of initiality, which is a second order characterization, is extended appropriately, however, by considering partial homomorphisms, then it also captures the notion of least definedness and thus of least fixed points.

For abstract types specifying programming languages by first order conditional equations such initial models can never be fully abstract in the sense of Milner [25]: the extensional equality of recursive functions cannot be expressed. However, fully abstract models, that give the "real" mathematical meaning, can be found by taking the terminal algebra in the class of models that are extensionally equivalent to the initial model.

Apart from being interested to find "the" meaning of a programming language, it is also appealing to consider the class of all models of it as specified by some algebraic theories. If the fixed point properties of the resp. programs are expressed properly, the class of models has a similar structure as the class of fixed points of some function. However, in addition each class of extensionally equivalent models (corresponding to particular fixed points) can be further structured by considering various congruence relations on the terms representing the functions.

Note, that we did not introduce any explicit notion of monotonicity or continuity for defining the semantics of our language. This is possible because partial functions and thus partial homomorphisms are monotonic if naturally extended to flat domains (cf. [23]).

The algebraic approach to language semantics is not restricted to applicative languages, i.e. recursive functions, but can also be applied for procedural
languages to define the semantics of program variables and assignments (cf. Pepper [27], Broy, Wirsing [8]), procedures (cf. Gaudel [17], Pair [26]), parallelism (cf. Broy [6], Broy, Wirsing [12]), or nondeterminism (cf. Broy, Wirsing [10]).

Different notions of equivalences of programs ranging from mathematical ("functional" or "extensional") equivalence to algorithmic (cf. Broy [6]) and to operational (computational) equivalence and at last to syntactic equality can contribute to the better understanding of the concepts of programming languages (cf. Broy et al. [14]).

Algebraic definitions of programming languages of the kind of type MAP may be viewed as restricting the class of possible semantic models of some programming language by specific axiomatic rules. If these axioms are weakly sufficiently complete and a weakly terminal \( fg \)-model exists, then such an algebraic definition can even be considered as a complete semantic definition by taking the weakly terminal \( fg \)-model as "mathematical semantics". Further complementary semantic definitions then can be verified to be consistent with the algebraic definition by showing their "extensional equivalence" to the partially initial \( fg \)-model.

ACKNOWLEDGEMENT

We like to thank our colleagues, P. Pepper for interesting discussions, and W. Dosch for reading carefully drafts.
