ALGEBRAIC AND TOPOLOGICAL THEORY OF LANGUAGES (*)

by J. Rhodes (1) and P. Weil (2)

Communicated by J.-E. Pin

Abstract. — A language is torsion (resp. bounded torsion, aperiodic, bounded aperiodic), if its syntactic monoid is torsion (resp. bounded torsion, aperiodic, bounded aperiodic). We generalize the regular language theorems of Kleene, Schützenberger and Straubing to describe the classes of torsion, bounded torsion, aperiodic and bounded aperiodic languages. These descriptions involve taking limits of sequences of languages and automata for certain topologies defined by filtrations of the free monoid. A theorem for arbitrary languages over finite alphabets is also stated and proved.

Résumé. — On dit qu’un langage est de torsion (resp. de torsion bornée, apériodique, apériodique borné) si son monoïde syntaxique est de torsion (resp. de torsion bornée, apériodique, apériodique borné). Nous généralisons les théorèmes sur les langages rationnels de Kleene, Schützenberger et Straubing pour décrire les classes des langages de torsion, de torsion bornée, apériodiques et apériodiques bornés. Ces descriptions imposent la considération de limites de suites de langages et d’automates pour certaines topologies définies par des filtrations du monoïde libre. Nous donnons également un théorème concernant les langages arbitraires sur des alphabets finis.

INTRODUCTION

The aim of this paper is to generalize the central results of the theory of rational, or recognizable languages (the languages which are recognized by finite automata) to a much wider class of languages over finite alphabets.

We rely in part on the powerful algebraic methods whose use is well-established for recognizable languages. In that more restrained framework, the relevant algebraic objects are the finite monoids. A standard algebraic way of generalizing finiteness is the concept of torsion: an algebraic object...
is torsion if each of its elements has only finitely many distinct powers, and it is bounded-torsion if the number of distinct powers of its elements is uniformly bounded above by some fixed integer. Around 1900 Burnside conjectured that all finitely generated bounded-torsion groups were finite. This was proved false 70 years later by Adjan-Novikov when the exponent is large and odd. More recently a shorter proof was given by Ol’shanskiï using small-cancellation diagrams (see [12]). More recently also, some important results on bounded-torsion monoids were obtained by Mc-Cammond [11], de Luca and Varricchio [2, 3] and Pereira do Lago [14]. Our main theorems deal with bounded torsion and torsion languages, that is, languages which are recognized by bounded torsion or torsion monoids. Such monoids were already considered by Rhodes [17, 18].

Another essential tool of our work reveals interesting connections with topology. Let $X$ be a finite alphabet. We say that a sequence $I = (I_n)_n$ of subsets of the free monoid $X^*$ is a filtration if $I_0 = X^*$, $I_{n+1} \subseteq I_n$ for all $n \geq 0$ and $\cap_n I_n = \emptyset$. Now a filtration $I$ gives rise to a topology on $X^* \cup \{\infty\}$ for which a basis of open sets is $\{\{w\}| w \in X^*\} \cup \{I_n \cup \{\infty\}| n \geq 0\}$. In particular a sequence of words $(w_n)_n$ tends to $\infty$ if and only if, for each $n \geq 0$, all but a finite number of the $w_k$ lie in $I_n$. This topology can then be extended to define the convergence of sequences of languages in $X^*$ and of sequences of automata over $X$: a sequence of languages $(L_n)_n$ tends to a language $L$ modulo $I$ if for each $n \geq 0$, there exist $k \geq 0$ such that $L_m \setminus I_n = L \setminus I_n$ for all $m \geq k$. In an analogous fashion, a sequence of automata $(A_n)_n$ tends to an automaton $A$ modulo $I$ if for each $n \geq 0$, there exists $k \geq 0$ such that, whenever $m \geq k$ and $u, v \notin I_n$, $(q_0^m \cdot u = q_0^m \cdot v) \Leftrightarrow (q_0 \cdot u = q_0 \cdot v)$ (where $q_0^m$ is the initial state of $A_m$ and $q_0$ the initial state of $A$).

Note that this notion of convergence modulo a filtration arises in an intuitive fashion when one considers classical machine models such as, say, Turing machines. For this model, we can consider bounding the amount of time or space or any suitable function of time and space, which we can call “stuff”, made available to the machine. Any Turing machine $M$, when restricted to using at most $n$ units of stuff, is equivalent to a finite-state machine $M_n$, and it is natural to try and view the language recognized by $M$ as “a limit” of the (rational) languages recognized by the $M_n$. If we let, for $n \geq 0$, $I_n$ be the set of all words $w \in X^*$ such that $M$ cannot make any decision using less than $n$ units of stuff upon reading $w$, then $I = (I_n)_n$ is a filtration and the language of $M$ is the limit of the languages of the $M_n$ with
respects to \( \mathcal{I} \). This idea is only intuitively presented here, but it is illustrated by a surprising result proved in the second appendix of this paper.

Our main results are characterizations of the classes \( \mathcal{L}_{\text{tor}} \), \( \mathcal{L}_{\text{btor}} \), \( \mathcal{L}_{\text{ap}} \) and \( \mathcal{L}_{\text{bap}} \), respectively of all torsion, bounded-torsion, aperiodic and bounded-aperiodic languages. (A monoid \( S \) is aperiodic if for each \( s \in S \) there exists \( n \geq 1 \) such that \( s^n = s^{n+1} \) and a language is aperiodic if it is recognized by an aperiodic monoid.) These characterizations generalize the theorems for Kleene, Schützenberger and Straubing on recognizable languages. Recall that these theorems state that the classes of rational (resp. rational aperiodic, rational subgroup-solvable) languages are the least classes containing the finite languages and closed under certain language operations (such as union, product, star, etc.) Our results characterize the classes \( \mathcal{L}_{\text{tor}} \), \( \mathcal{L}_{\text{btor}} \), \( \mathcal{L}_{\text{ap}} \) and \( \mathcal{L}_{\text{bap}} \) as the least classes containing the finite languages, closed under some of these language operations, and closed under taking certain limits with respect to certain filtrations.

Of course these results hint at a possible generalization of Eilenberg’s variety (or stream) theorem to classes of arbitrary languages (not just rational), and we explore and prove this generalization in our third appendix.

Part of the proof of these main results relies on combinatorial and algebraic methods more or less of the same flavor as the techniques used classically to deal with rational languages. The second part of these proofs uses in a crucial way the properties of the finitely generated Burnside monoids, recently established by McCammond [11] and Pereira do Lago [14], and the properties of two semigroup expansions which were studied by Birget, Rhodes and Henckell [1, 17, 6]. One of these expansions, \( S \mapsto \hat{S}^{(3)} \) is particularly interesting to illustrate another point of view on the generalization of finiteness, a concept underlying all of this paper. Given any finitely generated monoid \( S \), a finitely generated monoid \( \hat{S}^{(3)}(S) \) can be constructed along with an onto morphism \( \pi \) from \( \hat{S}^{(3)}(S) \) onto \( S \) such that:

1. \( \hat{S}^{(3)}(S) \) is “close” to \( S \) (technically, the inverse image by \( \pi \) of each idempotent of \( S \) satisfies the identity \( x^5 = x^6 \)), and
2. \( \hat{S}^{(3)}(S) \) contains a sequence of ideals \( (J_n)_n \) such that \( J_0 = \hat{S}^{(3)}(S) \), \( J_{n+1} \subseteq J_n \) for all \( n \) and \( \cap_n J_n = \emptyset \), and such that each Rees quotient \( \hat{S}^{(3)}(S)/J_n \) is finite.

This sequence of ideals \( (J_n)_n \) is of course reminiscent of our definition of a filtration over a free monoid. Then, if we consider the topology on \( \hat{S}^{(3)} \cup \{ \infty \} \) defined as above (with \( \{ \{ s \} \mid s \in \hat{S}^{(3)} \} \cup \{ J_n \cup \{ \infty \} \mid n \geq 0 \} \) as a basis of open sets), then \( \hat{S}^{(3)} \cup \{ \infty \} \) is compact. Note that compactness is another
natural generalization of finiteness. In fact, the result which we present in our second appendix is essentially an application of this construction, and we give its full details in that appendix.

The precise organization of this paper is the following. In Section 1, we present rapidly the basic definitions and properties of automata, semigroups and syntactic monoids, and review the statement of the theorems of Kleene, Schützenberger and Straubing. Section 2 is devoted to exploring the first properties of torsion and aperiodic monoids and languages. In Section 3 we introduce the notions of convergence of a sequence of languages and of a sequence of accessible automata modulo a given filtration. Our main theorems are stated in Section 4 and proved in Section 5.

We then consider in three subsequent appendices some connected results. The first one gives a variant of our results in terms of convergent sequences of onto morphisms. The second one is the description of a rational filtration which can be canonically associated to an arbitrary congruence on $X^*$, and the last one is the generalization to arbitrary classes of languages (over finite alphabets) of Eilenberg’s variety theorem.

We wish to acknowledge the special debt owed to Douglas Albert whose knowledge of computer science and insights he has so generously shared. Also this paper stems from a preliminary reprint of the same title as this paper, published by the first author as a report by the Center of Pure and Applied Mathematics of the University of California as MAP-180 in September 1983.

1. PRELIMINARIES

In this section we will review briefly the definition and basic properties of the objects that we will be dealing with, namely languages and automata. In particular we will remind the reader of the concept of recognizability of a language by a monoid, and we will recall some of the fundamental results of the theory of rational languages. For a more detailed presentation of the various aspects of the theory of languages and automata, the reader is referred to [13, 4, 10, 16].

1.1. Languages and automata

Throughout this paper, $X$ will denote a finite non-empty set called the alphabet. Its elements are called letters. Finite (possibly empty) sequences of letters are called words. The set $X^*$ of all words over the alphabet $X$ is a monoid under concatenation. Its identity is the empty word, denoted $1$. 
The monoid $X^*$ is the free monoid over $X$. A language over $X$ is any subset of $X^*$.

An automaton over $X$ is a 5-tuple $A = (Q, X, q_0, \lambda, F)$ where $Q$ is a countable (not necessarily finite) set called the state set, $q_0 \in Q$ is called the initial state, $\lambda : Q \times X \to Q$ is the transition function and $F \subseteq Q$ is called the set of final states. When there is no ambiguity as to which automaton is being discussed, we write $\lambda (q, x) = q \cdot x$ ($q \in Q$ and $x \in X$). The function $\lambda$ is extended to $\lambda : Q \times X^* \to Q$ by letting

$$
q \cdot 1 = q \quad \text{for all } q \in Q,
$$

$$
q \cdot wx = (q \cdot w) \cdot x \quad \text{for all } q \in Q, x \in X \text{ and } w \in X^*.
$$

We will always suppose our automata to be accessible, that is, they satisfy $q_0 \cdot X^* = Q$. The language recognized by $A$ is $L(A) = \{w \in X^* | q_0 \cdot w \in F\}$.

Let $L \subseteq X^*$ be a language. The translates of $L$ are the languages $u^{-1} L = \{v \in X^* | uv \in L\}$ ($u \in X^*$), $Lu^{-1} = \{v \in X^* | vu \in L\}$ ($u \in X^*$) and $u^{-1} Lu^{-1} = (u^{-1} L) v^{-1} = u^{-1} (L v^{-1})$ ($u, v \in X^*$).

It is easy to verify that, for each $u, v \in X^*$, then $u^{-1} (v^{-1} L) = (vu)^{-1} L$. Let us note also the following simple remark. If $A_0 = (Q, X, q_0, \lambda, F)$ is an automaton, if $u \in X^*$ and $q_1 = q_0 \cdot u$, let $A_1 = (Q, X, q_1, \lambda, F)$. Then $L (A_1) = u^{-1} L (A_0)$.

To each language $L \subseteq X^*$ we associate a canonical automaton $A_L = (Q, X, q_0, \lambda, F)$ in the following way:

$$
Q = \{u^{-1} L | u \in X^*\}, \quad q_0 = L = 1^{-1} L,
$$

$$
F = \{u^{-1} L | u \in X^* \text{ and } 1 \in u^{-1} L\},
$$

$$
\lambda(u^{-1} L, x) = (ux)^{-1} L \quad \text{for } u \in X^* \text{ and } x \in X.
$$

In this automaton, for all $w \in X^*$, we have

$$
q_0 \cdot w = (1^{-1} L) \cdot w = w^{-1} L.
$$

Therefore $w \in L (A_L)$ if and only if $1 \in w^{-1} L$, that is, if and only if $w \in L$. Thus $L (A_L) = L$. This shows in particular that every language is recognized by some automaton. In general, a language can be recognized by several different automata. However, $A_L$ is the minimal automaton of $L$ in the following sense.
PROPOSITION 1.1: Let $L \subseteq X^*$, let $A(L) = (Q_L, X, \lambda_L, F_L)$ and let $A = (Q, X, q_0, \lambda, F)$ be any automaton recognizing $L$. Then there exists a surjective mapping $\pi : Q \rightarrow Q_L$ such that $q_0 \pi = L, F \pi = F_L$ and $q \pi \cdot u = (q \cdot u) \pi$ for all $q \in Q$ and $u \in X^*$. (We say that $A$ reduces to $A(L)$.) Furthermore, if $B$ is another automaton such that each automaton recognizing $L$ reduces to $B$, then $B$ is isomorphic to $A(L)$.

Proof: Well-known. $\square$

In the sequel it will be convenient to consider automata with unspecified set of final states, that is, of the form $(Q, X, q_0, \lambda)$. We still call these objects automata and we let $A(X)$ be the class of all automata with unspecified set of final states over $X$. If $A \in A(X)$, we let $L(A)$ be the set of all the languages that are recognized by $A$ (when the set of final states assumes all possible values).

1.2. Syntactic monoids

We first recall a few basic notions on semigroups. Readers are referred to [4, 10, 16, 8] for more details. A semigroup is a pair $(S, \cdot)$ where $S$ is a set and $\cdot$ is an associative binary operation on $S$. In a semigroup $S$, an idempotent is an element $e$ such that $e^2 = e$. An identity (resp. zero) is an idempotent $e$ such that $es = se = s$ (resp. $es = se = e$) for all $s \in S$. An identity (resp. zero) is usually denoted $1$ (resp. $0$). Any semigroup has at most one identity (resp. zero), but it may have an unrestricted number of idempotents. We say that $S$ is a monoid if it has an identity. If $S$ is a semigroup we define $S^1$ to be the monoid equal to $S$ if $S$ is a monoid, and to $S \cup \{1\}$ otherwise (where $1$ is an adjoined identity).

If $A, B \subseteq S$, we let $AB = \{ab | a \in A, b \in B\}$. Then the power set of $S$, $P(S)$, is a semigroup. If $T \subseteq S$ and $T^2 \subseteq T$, we say that $T$ is a subsemigroup of $S$. Let $A \subseteq S$. The subsemigroup $\langle A \rangle$ generated by $A$ is the least subsemigroup of $S$ containing $A$, that is, the set $\bigcup_n A^n$ of all finite products of elements of $A$. We say that $A$ generates $S$ if $S = \langle A \rangle$ and that $S$ is finitely generated if $S$ is generated by a finite set.

An ideal of a semigroup $S$ is a subset $I$ of $S$ such that $S^1IS^1 = I$. If $I$ is a non-empty ideal of $S$, a new semigroup $(S/I, \cdot)$ is constructed, called the Rees quotient of $S$ by $I$, by letting $S/I = S \setminus I \cup \{0\}$ and, for $s, s' \in S/I$, $s \cdot s' = \begin{cases} ss' & \text{if } ss' \notin I, \\ 0 & \text{otherwise.} \end{cases}$

Informatique théorique et Applications/Theoretical Informatics and Applications
If $S$ and $T$ are semigroups, a morphism $\varphi : S \to T$ is a mapping such that $(ss') \varphi = (s \varphi)(s' \varphi)$ for all $s, s' \in S$. When $S$ and $T$ are both monoids, we will implicitly assume that $1 \varphi = 1$. We say that $T$ divides $S$ if there exists a surjective morphism from a subsemigroup of $S$ onto $T$. If $I$ is a non-empty ideal of $S$, then the canonical projection $\pi : S \to S/I$ defined by

$$s\pi = \begin{cases} s & \text{if } s \notin I, \\ 0 & \text{otherwise.} \end{cases}$$

is an onto morphism. A congruence on a semigroup $S$ is an equivalence relation $\sim$ such that, for all $s, s' \in S$ and $u, v \in S^1$, $s \sim s'$ implies $usv \sim us'v$. If $\varphi : S \to T$ is a morphism and if we define $\sim_{\varphi}$ on $S$ by $s \sim_{\varphi} s'$ if and only if $s \varphi = s' \varphi$, then $\sim_{\varphi}$ is a congruence. Conversely, if $\sim$ is a congruence, then the set $S/\sim$ of $\sim$-classes is naturally equipped with a semigroup structure given by $[s] \cdot [s'] = [ss']$ for all $s, s' \in S$ (where $[s]$ is the $\sim$-class of $s$). The canonical projection from $S$ onto $S/\sim$ is a morphism.

Morphisms on free monoids will be crucial in the sequel. Let $S$ be a monoid and let $X$ be an alphabet. Recall that, for any mapping $\varphi : X \to S$, there exists a unique morphism from $X^*$ into $S$ extending $\varphi$.

Let $A = (Q, X, q_0, \lambda) \in A(X)$ be an automaton. For each word $u \in X^*$, let $u\mu$ be the function from $Q$ to $Q$ given by $q \mapsto q \cdot u$. Then $\mu$ defines a morphism from $X^*$ into the monoid of functions from $Q$ into itself (a monoid under the compositions of functions). We say that $\mu$ is the transition morphism of $A$ and we denote the image of $\mu$ by $S(A)$, the transition monoid of $A$. Note that $\mu$ and $S(A)$ depend only on $Q, X$ and $\lambda$. Let $L$ be a language recognized by $A$ with set of final states $F$, and let $P$ be the set of functions from $Q$ to $Q$ which map $q_0$ to an element of $F$. Then $L = P\mu^{-1}$.

In general we say that a morphism $\varphi : X^* \to S$ recognizes a language $L \subseteq X^*$ if there exists a subset $P$ of $S$ such that $L = P\varphi^{-1}$. Thus, if an automaton recognizes $L$, then its transition morphism recognizes $L$ as well. Conversely, let $\varphi : X^* \to S$ be an onto morphism recognizing a language $L$. Then $L = P\varphi^{-1}$ for some $P \subseteq S$. We define an automaton $A(S) = (S^1, X, 1, \lambda) \in A(X)$ by letting $\lambda(s, x) = s(x\varphi)$ ($s \in S^1$ and $x \in X$). If we choose $P$ for the set of final states, then this automaton recognizes $L$.

Let $L \subseteq X^*$. The syntactic congruence $\equiv_L$ in $X^*$ is the largest (coarsest) congruence for which $X$ is a union of classes. One can easily prove (see for instance [4, 10]) that $\equiv_L$ in $X^*$ is given by

$$w_1 \equiv_L w_2 \quad \text{if and only if} \quad \forall u, v \in X^*, \ uv_1 v \in L \iff uv_2 v \in L.$$
The quotient monoid $X^*/ \equiv L$ is called the **syntactic monoid** of $L$ and is denoted $S(L)$. The **syntactic morphism** of $L$ is the canonical projection from $X^*$ onto $S(L)$. By definition of $\equiv L$, the language $L$ is recognized by its syntactic morphism. Furthermore, the following results are well-known (see [4, 16]). $SLT$ means $S \iff T$.

**Proposition 1.2:** Let $L \subseteq X^*$, and let $\eta_L : X^* \rightarrow S(L)$ be its syntactic morphism.

1. $\eta_L$ is the transition morphism of the minimal automaton $A(L)$ of $L$.
2. If a morphism $\varphi : X^* \rightarrow S$ recognizes $L$, then $S(L) \subseteq S$.

Let $L_1, \ldots, L_n$ be finitely many languages in $X^*$. We define $BT(L_1, \ldots, L_n)$ to be the least family of languages of $X^*$ containing the languages of the form $u^{-1}L_iv^{-1} (1 \leq i \leq n$ and $u, v \in X^*)$ and closed under complement and arbitrary unions and intersections.

**Proposition 1.3:** (Little boxes theorem) Let $L_1, \ldots, L_n$ be finitely many languages in $X^*$ and let $\eta_i : X^* \rightarrow S(L_i)$ be their respective syntactic morphisms. Let $\eta$ be the morphism from $X^*$ into $S(L_1) \times \cdots \times S(L_n)$ defined by $w\eta = (w\eta_1, \ldots, w\eta_n)$. Then $L \in BT(L_1, \ldots, L_n)$ if and only if $L$ is recognized by $\eta$.

**Proof:** The proof relies on the following important remark: Let $w \in X^*$. Then

$$w\eta_i\eta_i^{-1} = \bigcup u^{-1}L_iv^{-1} \setminus \bigcup x^{-1}L_iv^{-1}$$

where the first union runs over all pairs of words $(u, v)$ such that $uwv \in L_i$, and the other union runs over all pairs $(x, y)$ such that $xwy \notin L_i$. This is immediate by the characterization of the syntactic congruence.

Now, if $w \in X^*$, then $w\eta\eta^{-1} = \bigcap_{i=1}^n w\eta_i\eta_i^{-1}$. So the languages recognized by $\eta$ are all in $BT(L_1, \ldots, L_n)$. Conversely let us remark that if $w\eta_i = w'\eta_i$ and $w \in u^{-1}L_iv^{-1}$ for some $i, u$ and $v$, then $w' \in u^{-1}L_iv^{-1}$. That is, each $u^{-1}L_iv^{-1}$ is recognized by the morphism $\eta_i$ and hence by the morphism $\eta$. On the other hand, any Boolean combination (using complement and arbitrary unions and intersections) of languages recognized by $\eta$ is also recognized by $\eta$. So every language in $BT(L_1, \ldots, L_n)$ is recognized by $\eta$. \qed

**Corollary 1.4:** The set of languages recognized by the minimal automaton of a language $L$ is $BT(L)$. 

Informatique théorique et Applications/Theoretical Informatics and Applications
1.3. Rational languages

If \( L, L' \subseteq X^* \), we define the product \( LL' \) and the star \( L^* \) by

\[
LL' = \{ww' | w \in L, w' \in L\} \quad \text{and} \quad L^* = \{1 \} \cup \{w_1 \ldots w_n | n \geq 1, \ w_i \in L \ \text{for all} \ i\}.
\]

The class of rational languages over \( X \) is the least class of languages containing the finite subsets of \( X^* \) and closed under union, product and star. The following theorem, due to Kleene [9] is a fundamental result of the theory of rational languages.

**Theorem 1.5:** (Kleene’s theorem) Let \( L \subseteq X^* \). The following are equivalent.

1. \( L \) is rational.
2. \( L \) is recognized by a finite automaton.
3. \( L \) is recognized by a finite monoid.
4. \( A(L) \) is finite.
5. \( S(L) \) is finite.

Proposition 1.3 implies immediately the following corollary.

**Corollary 1.6:** If \( L_1, \ldots, L_n \subseteq X^* \) are rational languages, then \( BT(L_1, \ldots, L_n) \) is a finite set of languages, all of which are rational.

An important subclass of the rational languages is the class of star-free languages: it is the least class containing the finite sets and closed under Boolean operations and product. Schützenberger [19] gave the following characterization of the star-free languages. We say that a monoid \( S \) is aperiodic if

\[
\forall s \in S, \ \exists n \geq 1, \ s^{n+1} = s^n.
\]

**Theorem 1.7:** (Schützenberger’s theorem) Let \( L \subseteq X^* \). The following are equivalent.

1. \( L \) is star-free.
2. \( L \) is recognized by a finite aperiodic monoid.
3. \( S(L) \) is finite and aperiodic.

Again we have

vol. 29, no 1, 1995
Corollary 1.8: If \( L_1, \ldots, L_n \subseteq X^* \) are star-free languages, then all the languages in \( BT \{L_1, \ldots, L_n\} \) are star-free.

Because of Schützenberger's theorem, star-free languages are also called rational aperiodic languages. It is not difficult to verify that a finite monoid is aperiodic if and only if its subgroups are trivial.

Two other subclasses of the rational languages will be of interest for us. We say that a language \( L \) is rational subgroup-cyclic (resp. rational subgroup-solvable) if each subgroup of its syntactic monoid is cyclic (resp. solvable). In particular each star-free language is rational subgroup-cyclic and each rational subgroup-cyclic language is rational subgroup-solvable. If \( L \subseteq X^* \), if \( p \) is prime and \( 0 < q < p \), we define \( \langle L, p, q \rangle \) to be the set of all words \( w \) having a number of prefixes in \( L \) congruent to \( q \) mod \( p \). Straubing [20] proved the following characterization of rational subgroup-solvable languages.

Theorem 1.9: (Straubing's theorem) Let \( L \subseteq X^* \). The following are equivalent.

1. \( L \) can be obtained from the finite subsets of \( X^* \) using only Boolean operations, products and operations of the form \( L \mapsto \langle L, p, q \rangle \) where \( p \) is prime and \( 0 < q < p \).
2. \( L \) is recognized by a finite monoid all of whose subgroups are solvable.
3. \( L \) is finite subgroup-solvable.

Corollary 1.10: If \( L_1, \ldots, L_n \subseteq X^* \) are rational subgroup-solvable, then all the languages in \( BT \{L_1, \ldots, L_n\} \) are rational subgroup-solvable.

2. TORSION AND APERIODIC LANGUAGES AND SEMIGROUPS

Let \( S \) be a semigroup. We say that \( S \) is torsion if

\[
\forall s \in S, \quad \exists n \geq 1, \quad s^n \text{ is idempotent.}
\]

For \( n \geq 1 \), we say that \( S \) is \( n \)-bounded-torsion if \( s^n \) is idempotent for all \( s \) in \( S \). Finally we say that \( S \) is bounded-torsion if \( S \) is \( n \)-bounded-torsion for some \( n \). We denote by \( \text{Tor} \), \( b\text{Tor} \) and \( b\text{Tor}_n \) the classes of torsion, bounded-torsion and \( n \)-bounded-torsion semigroups. All finite semigroups are bounded-torsion.

Recall that \( S \) is aperiodic if

\[
\forall s \in S, \quad \exists n \geq 1, \quad s^n = s^{n+1}.
\]
We say that $S$ is $n$-bounded-aperiodic for $n \geq 1$ if $s^n = s^{n+1}$ for all $s \in S$. Finally we say that $S$ is bounded-aperiodic if $S$ is $n$-bounded-aperiodic for some $n$. We denote by $\text{Ap}$, $\text{bAp}$ and $\text{bAp}_n$ the classes of aperiodic, bounded-aperiodic and $n$-bounded-aperiodic semigroups. Notice that finite aperiodic semigroups are bounded-aperiodic. The following important properties are easily verified.

**Proposition 2.1:** The following strict containments hold:

$$\text{bAp}_n \subset \text{bAp}_{n+1}, \quad \text{bTor}_n \subset \text{bTor}_{n+1}, \quad \text{bTor}_n \cap \text{Ap} = \text{bAp}_n$$

$$\text{bAp}_n \subset \text{bTor}_n, \quad \text{bAp} \subset \text{bTor}, \quad \text{Ap} \subset \text{Tor}.$$

If $T$ divides $S$ and $S$ is in $\text{Tor}$ (resp. $\text{Ap}$, $\text{bTor}$, $\text{bAp}$, $\text{bTor}_n$, $\text{bAp}_n$), then so is $T$.

The classes $\text{Tor}$, $\text{bTor}$, $\text{Ap}$ and $\text{bAp}$ are closed under finite direct product and the classes $\text{bTor}_n$ and $\text{bAp}_n$ ($n \geq 1$) are closed under arbitrary direct product.

We will also use the following property of the classes $\text{Tor}$, $\text{Ap}$, $\text{bTor}$, $\text{bAp}$, $\text{bTor}_n$ and $\text{bAp}_n$. Let $\pi : S \to T$ be a morphism. We say that $\pi$ is torsion (resp. aperiodic, $n$-bounded-torsion, $n$-bounded-aperiodic) if, for each idempotent $e$ of $T$, the semigroup $e\pi^{-1}$ is in $\text{Tor}$ (resp. $\text{Ab}$, $\text{bTor}_n$, $\text{bAp}_n$). We say that $\pi$ is bounded-torsion (resp. bounded-aperiodic) if there exists $n \geq 1$ such that $\pi$ is $n$-bounded-torsion (resp. $n$-bounded-aperiodic). Note that this is different from requiring that $e\pi^{-1} \in \text{bTor}$ (resp. $\text{bAp}$) for each idempotent $e$ of $T$.

**Proposition 2.2:** Let $\pi : S \to T$ be a morphism.

1. If $T \in \text{Tor}$ (resp. $\text{Ap}$) and $\pi$ is a torsion (resp. aperiodic) morphism, then $S \in \text{Tor}$ (resp. $\text{Ap}$).

2. Let $\pi$, $\pi' \geq 1$. If $T \in \text{bTor}_n$ (resp. $\text{bAp}_n$) and $\pi$ is a $n'$-bounded-torsion (resp. $n'$-bounded-aperiodic) morphism, then $S \in \text{bTor}_{nn'}$ (resp. $\text{bAp}_{n+n'}$).

3. If $T \in \text{bTor}$ (resp. $\text{bAp}$) and $\pi$ is a bounded-torsion (resp. bounded-aperiodic) morphism, then $S \in \text{bTor}$ (resp. $\text{bAp}$).

**Proof:** We prove (1) for torsion semigroups and morphisms. The other proofs are similar. Let $\pi : S \to T$ be a torsion morphism with $T \in \text{Tor}$. Let $s \in S$. Then $(s\pi)^n = (s\pi)^{2n}$ for some $n \geq 1$. Thus $e = s^n\pi$ is an idempotent of $T$ and $s^n \in \epsilon\pi^{-1}$. Since $e\pi^{-1} \in \text{Tor}$, there exists $n' \geq 1$ such that $(s^n)^{n'} = (s^n)^{2n'}$, that is $s^{nn'} = s^{2nn'}$. So $S \in \text{Tor}$. □
We now turn to languages. We say that a language $L \subseteq X^*$ is torsion (resp. aperiodic, bounded-torsion, bounded-aperiodic, $n$-bounded-torsion, $n$-bounded-aperiodic ($n \geq 1$)) if it is recognized by some automaton $A$ such that $S(A) \in \text{Tor}$ (resp. $A_{\text{ap}}, b_{\text{Tor}}, b_{\text{Tor}}^n, b_{\text{Ap}}^n$). We denote these classes of languages by $\mathcal{L}_{\text{tor}}, \mathcal{L}_{\text{ap}}, \mathcal{L}_{b_{\text{tor}}}, \mathcal{L}_{b_{\text{ap}}}, \mathcal{L}_{b_{\text{tor}}}^{(n)}, \mathcal{L}_{b_{\text{ap}}}^{[n]}$. Of course we have

$$\mathcal{L}_{b_{\text{ap}}}^{[n]} \subseteq \mathcal{L}_{b_{\text{ap}}}^{[n+1]}, \quad \mathcal{L}_{b_{\text{tor}}}^{(n)} \subseteq \mathcal{L}_{b_{\text{tor}}}^{(n+1)}, \quad \mathcal{L}_{b_{\text{tor}}}^{(n)} \cap \mathcal{L}_{\text{ap}} = \mathcal{L}_{b_{\text{ap}}}^{[n]}$$

$$\mathcal{L}_{b_{\text{ap}}}^{[n]} \subseteq \mathcal{L}_{b_{\text{tor}}}^{(n)}, \quad \mathcal{L}_{b_{\text{ap}}} \subseteq \mathcal{L}_{b_{\text{tor}}}, \quad \mathcal{L}_{\text{ap}} \subseteq \mathcal{L}_{\text{tor}}.$$

Since rational languages are recognized by finite automata, all rational languages are bounded-torsion and all star-free languages are bounded-aperiodic. Note also the following proposition, which is immediate using Propositions 1.2 and 2.1.

**Proposition 2.3:** Let $L \subseteq X^*$. $L$ is torsion (resp. bounded-torsion, $n$-bounded-torsion, aperiodic, bounded-aperiodic, $n$-bounded-aperiodic) if and only if it is recognized by a monoid in $\text{Tor}$ (resp. $b_{\text{Tor}}, b_{\text{Tor}}^n, A_{\text{p}}, b_{\text{Ap}}, b_{\text{Ap}}^n$), if and only if $S(L)$ is in $\text{Tor}$ (resp. $b_{\text{Tor}}, b_{\text{Tor}}^n, A_{\text{p}}, b_{\text{Ap}}, b_{\text{Ap}}^n$).

It is well-known that not all torsion languages are aperiodic. For instance the language of all words of even length on an alphabet $X$ is rational but not aperiodic.

The set of all square-free words over a 3-letter alphabet is an aperiodic language which is not rational. More precisely, this language is in $\mathcal{L}_{A_{\text{p}}}^{[2]}$. This is a consequence of the existence of an infinite square-free word over a 3-letter alphabet.

Torsion and bounded torsion groups have received considerable attention. Examples of finitely generated torsion groups which are not bounded-torsion were exhibited by Golod and Shafarevitch (see Herstein [7]), by Grigorchuk [5], etc. These provide examples of torsion languages which are not bounded-torsion. The existence of infinite (Burnside) groups with two generators and fixed exponent $k$ (for $k$ large enough and odd) provides other examples of languages that are bounded-torsion and not rational. See [12].

Finally, not all languages are torsion. For instance the Dyck language $D$ over two letters, defined by

$$D_0 = \{1\}, \quad D_{n+1} = (bD_n^*a)^* \quad \text{and} \quad D = \bigcup_{n \geq 0} D_n$$

is not a torsion language.
Let \( w \) be a non-empty word. Recall that \( w^* = \{w^n | n \geq 0\} \) and that \( w \) is primitive if \( w \in u^* \) implies \( w = u \). In particular each non-empty word is a power of a primitive word. For \( L \subseteq X^* \) we define \( K(L, w) \) by \( K(L, w) = \{k \geq 0 | w^k \in L\} \). Let \( n \geq 1 \). We say that a set \( K \) of integers is ultimately \( n \)-periodic if there exists \( t \geq 0 \) such that \( k \geq t \) and \( k \in K \) implies \( k + n \in K \). We say that \( K \) is ultimately periodic if it is ultimately \( n \)-periodic for some \( n \). When \( n = 1 \) we speak of an ultimately aperiodic set of integers. The least \( t \) for which the above implication holds is called the threshold.

We have the following characterization of the classes \( L\text{tor}, L\text{ap}, L^{(n)}\text{tor} \) and \( L^{[n]}\text{ap} \).

**Proposition 2.4:** Let \( L \subseteq X^* \) and let \( n \geq 1 \).

1. \( L \in L\text{tor} \) if and only if, for all \( L' \in BT(L) \) and for all \( w \in X^* \), \( L' \cap w^* \) is rational and aperiodic, which is equivalent to requesting that \( L' \cap w^* \in L\text{tor} \) or that \( K(L', w) \) be ultimately periodic.

2. \( L \in L\text{ap} \) if and only if, for all \( L' \in BT(L) \) and for all \( w \in X^* \), \( L' \cap w^* \) is rational and aperiodic, which is equivalent to requesting that \( L' \cap w^* \in L\text{ap} \) or that \( K(L', w) \) be ultimately aperiodic.

3. \( L \in L^{(n)}\text{tor} \) if and only if, for all \( L' \in BT(L) \) and for all \( w \in X^* \), \( K(L', w) \) is ultimately \( n \)-periodic with threshold \( n \).

4. \( L \in L^{[n]}\text{ap} \) if and only if, for all \( L' \in BT(L) \) and for all \( w \in X^* \), \( K(L', w) \) is ultimately aperiodic with threshold \( n \).

5. Statements (1)-(4) above still hold if we restrict the words \( w \) to being primitive.

**Proof:** Let us prove (1) and the corresponding assertion of (5). Let us first assume that \( L \in L\text{tor} \), and let \( L' \in BT(L) \) and \( w \in X^* \). By Corollary 1.4, \( L' \) is recognized by the syntactic morphism of \( L \) and by Proposition 2.3 this implies that \( L' \in L\text{tor} \). Therefore there exists \( n \geq 1 \) such that \( w^n \equiv w^{2n} \) where \( \equiv \) is the syntactic congruence of \( L' \), and hence \( w^k \equiv w^{k+n} \) for all \( k \geq n \). Thus \( K(L', w) \) is ultimately \( n \)-periodic with threshold \( n \). Therefore

\[
L' \cap w^* = \{w^k | k < n \text{ and } w^k \in L'\} \cup \bigcup_{n \leq k < 2n} w^k (w^n)^*
\]

is rational (and hence torsion).

For the converse let us assume that \( L \notin L\text{tor} \) and let \( \eta_L \) be its syntactic morphism. Then there exists \( w \in X^* \) such that the \( w^n \eta_L \) are pairwise
distinct. We can further assume that $w$ is primitive. Let now $K$ be a non-
ultimately periodic set of integers, say $K$ is the set of all primes, and let $P = \{w^k\eta_L | k \in K\}$. Let $L' = P\eta_L^{-1}$. Then $L'$ is recognized by $\eta_L$, so that $L' \in BT(L)$. But $K(L', w) = K$ which is not ultimately periodic.

The first part of this proof can be easily adapted to show that if $L \in \mathcal{L}_{\text{ap}}$ (resp. $\mathcal{L}_{\text{btor}}$, $\mathcal{L}_{\text{bap}}$), then $K(L', w)$ is ultimately aperiodic (resp. ultimately $n$-periodic with threshold $n$, ultimately aperiodic with threshold $n$) for all $L' \in BT(L)$ and $w \in X^*$, that is, the direct part of statements (2) to (4). For
the converse part in statement (2), we consider $L \notin \mathcal{L}_{\text{ap}}$ and $\eta_L$ its syntactic morphism. We already know that if $L \notin \mathcal{L}_{\text{tor}}$ then we can find $L' \in BT(L)$ and $w$ a primitive word such that $K(L', w)$ is not ultimately periodic. Let us now assume that $L \in \mathcal{L}_{\text{tor}} \setminus \mathcal{L}_{\text{ap}}$. Then there exists a word $w$ in $X^*$ (which can be assumed to be primitive) such that $w^*\eta_L$ consists of exactly $a + b$ elements $1, w_1\eta_L, \ldots, w_a\eta_L, w^{a+1}\eta_L, \ldots, w^{a+b-1}\eta_L$ with $w^a\eta_L = w^{a+b}\eta_L$, $a \geq 0$ and $b \geq 2$. Let $P = w^a\eta_L$ and $L' = P\eta_L^{-1}$. Then $L'$ recognized by $\eta_L$ and hence $L' \in BT(L)$. Furthermore $K(L', w) = \{a + bk | k \geq 0\}$, which is not ultimately aperiodic.

Similarly, for the converse part of statement (3) (resp. (4)), it is sufficient to consider $L \in \mathcal{L}_{\text{tor}} \setminus \mathcal{L}_{\text{ap}}$ (resp. $\mathcal{L}_{\text{tor}} \setminus \mathcal{L}_{\text{bap}}$) and $\eta_L$ its syntactic morphism. Then there exists $w \in X^*$ (which can be assumed to be primitive) such that $w^a\eta_L \neq w^{2n}\eta_L$ (resp. $w^n\eta_L \neq w^{n+1}\eta_L$). If we let $P = w^n\eta_L$ and $L' = P\eta_L^{-1}$, then $L' \in BT(L)$ and $K(L', w)$ contains $n$ but not $2n$ (resp. $n + 1$), so $K(L', w)$ is not ultimately $n$-periodic (resp. ultimately aperiodic) with threshold $n$.

Finally we note the following characterization of automata whose transition monoid is torsion or aperiodic.

**Proposition 2.5:** Let $A = \langle Q, X, q_0, \lambda \rangle \in \mathcal{A}(X)$. Then $\mathcal{L}(A) \subseteq \mathcal{L}_{\text{tor}}$ (resp. $\mathcal{L}_{\text{ap}}$) if and only if $S(A) \in \text{Tor}$ (resp. $\text{Ap}$).

**Proof:** If $S(A) \in \text{Tor}$ (resp. $\text{Ap}$), then $\mathcal{L}(A) \subseteq \mathcal{L}_{\text{tor}}$ (resp. $\mathcal{L}_{\text{ap}}$) by definition. We prove the converse statement concerning torsion languages. This proof can easily be modified to prove the aperiodic case. Let $\mu : X^* \to S(A)$ be the transition morphism of $A$. We assume that $S(A) \notin \text{Tor}$ and we will prove that $\mathcal{L}(A) \notin \mathcal{L}_{\text{tor}}$. Since $S(A) \notin \text{Tor}$, there exists $w \in X^*$ such that the $w^n\mu$ are pairwise distinct. *First case.* $\exists q \in Q, \forall a, b \geq 1, q \cdot w^a \neq q \cdot w^{a+b}$.

Let $F = \{q \cdot w^k | \text{prime}\}$ and let $L$ be recognized by $A$ with $F$ as the set of final states. Let $u \in X^*$ be such that $q_0 \cdot u = q$ and let $L' = u^{-1}L$. Then
$K(L', w) = \{k \geq 1 | w^k \in L\}$ is the set of prime numbers, which is not ultimately periodic. So Proposition 2.4 shows that $L$ is not torsion.

Second case. \forall q \in Q, \exists a, b \geq 1, q \cdot w^a = q \cdot w^{a+b}$.

For each $q \in Q$ let $C_q$ be the “cyclic” part of $q \cdot w^*$, that is,

$$C_q = \{q' \in Q | \exists a, b \geq 1, q \cdot w^a = q \cdot w^{a+b} = q'\}.$$

Let $a_q \geq 0$ be minimum such that $q \cdot w^{a_q} \in C_q$ and let $b_q \geq 1$ be minimum such that $q \cdot w^{a_q} = q \cdot w^{a_q + b_q}$. Note that $C_q = \{q \cdot w^n | n \geq a_q\}$ has cardinality $b_q$. Furthermore the sets $C_q$ are pairwise disjoint. Since $S(A) \notin \text{Tor}$, either the set $\{a_q | q \in Q\}$ or the set $\{b_q | q \in Q\}$ is unbounded. Therefore we can choose a sequence $(q_n)_n$ of states such that we have

either : $a_{q_1} < a_{q_2} < \ldots < a_{q_n} < \ldots$

or : $b_{q_1} < b_{q_2} < \ldots < b_{q_n} < \ldots$

Let us first assume that $a_{q_1} < a_{q_2} < \ldots$ Let $L$ be the language recognized by $A$ with set of final states $\bigcup_{n \geq 1} C_{q_n}$ and let $\equiv_L$ be its syntactic congruence.

Note that if $u \in X^*$ and $q_0 \cdot u = q_n$, then $uw^m \in L$ if and only if $m \geq a_{q_n}$.

If $L$ is torsion there exists $a, b \geq 1$ such that $w^a \equiv_L w^{a+b}$. Let us choose $n$ and $m$ such that $a < a_{q_n} < a + mb$, and let $u \in X^*$ be such that $q_0 \cdot u = q_n$. Then $uw^a \notin L$ and $uw^{a+mb} \in L$, thus contradicting $w^a \equiv_L w^{a+b}$. So $L$ is not torsion.

Let us first assume that $b_{q_1} < b_{q_2} < \ldots$ Let $L$ be the language recognized by $A$ with set of final states $\{q_n \cdot w^{a+n} | n \geq 1\}$ and let $\equiv_L$ be its syntactic congruence. We notice that if $u \in X^*$ and $q_0 \cdot u = q_n \cdot w^{a+n}$ then $uw^m \in L$ if and only if $m \equiv 0 (\text{mod } b_{q_n})$. As before, if $L$ is torsion there exists $a, b \geq 1$ such that $w^a \equiv_L w^{a+b}$. Let $n$ be such that $a + b < b_{q_n}$ and let $c = b_{q_n} - (a + b)$. Then $a + b + c \equiv 0 (\text{mod } b_{q_n})$ but $a + 2b + c \not\equiv 0 (\text{mod } b_{q_n})$. Therefore if $q_0 \cdot u = q_n \cdot w^{a+n}$ ($u \in X^*$) then $uw^{a+b+c} \in L$ and $uw^{a+2b+c} \notin L$, thus contradicting $w^a \equiv_L w^{a+b}$. So $L$ is not torsion.

3. FILTRATIONS AND LIMITS OF SEQUENCES OF LANGUAGES AND MORPHISMS

This section is devoted to the concept of a topology on $X^*$ defined by a filtration and to the notions of convergence of sequences of languages and of sequences of automata over $X$.
3.1. Topology induced by a filtration

Let $X$ be a finite alphabet. A filtration $\mathcal{I}$ of $X^*$ is a sequence of languages $\mathcal{I} = (I_n)_{n \geq 0}$ such that

$$X^* = I_0 \supseteq I_1 \supseteq \ldots \supseteq I_n \supseteq \ldots$$

and such that $\bigcap_{n \geq 0} I_n = \emptyset$. We say that $\mathcal{I}$ is in a class of languages $\mathcal{C}$ if each $I_n$ is in $\mathcal{C}$. We will be interested in particular in rational filtrations (each $I_n$ is a rational language) and in ideal filtrations ($I_n = X^*I_nX^*$ for each $n \geq 0$).

Let $\overline{X^*}$ be the monoid $\overline{X^*} = X^* \cup \{\infty\}$ consisting of $X^*$ and a new element $\infty$ such that

$$x(\infty) = (\infty) x = \infty, \quad \text{for all } x \in X^*.$$ 

Note that $\infty$ is a zero of $\overline{X^*}$ and that $X^*$ is a submonoid of $\overline{X^*}$. It is classical to consider the topology $\text{Top}_\mathcal{I}$ on $\overline{X^*}$ defined by a filtration $\mathcal{I} = (I_n)_{n}$ on $X^*$. For this topology, a basis for the open sets is

$$\{\{w\} \mid w \in X^*\} \cup \{I_n \cup \{\infty\} \mid n \geq 0\}.$$

For example, let $\overline{\mathbb{N}} = \{1, 2, \ldots, n, \ldots\} \cup \{\infty\}$ be the one-point compactification of the positive integers: a basis for the open sets of $\overline{\mathbb{N}}$ is

$$\{\{n\} \mid n \geq 1\} \cup \{F_n \cup \{\infty\} \mid n \geq 1\}$$

where $F_n = \{i \in \overline{\mathbb{N}} \mid i > n\}$.

If $\mathcal{I} = (I_n)_{n}$ is a filtration on $X^*$, we define a function $r_\mathcal{I} : \overline{X^*} \to \overline{\mathbb{N}}$ by $r_\mathcal{I}(\infty) = \infty$ and, for $w \in X^*$,

$$r_\mathcal{I}(w) = \min \{n \geq 0 \mid w \in I_n\}.$$ 

In other words, if $w \in X^*$, then

$$r_\mathcal{I}(w) = n \quad \text{if and only if} \quad w \in I_k \text{ for all } k < n, \text{ and } w \not\in I_k \text{ for all } k \geq n.$$ 

Therefore $r_\mathcal{I}^{-1}(F_n \cup \{\infty\}) = I_n \cup \{\infty\}$. In particular, $\text{Top}_\mathcal{I}$ is the last topology on $\overline{X^*}$ that makes $r_\mathcal{I}$ continuous. It is easy to verify that a sequence $(w_n)_{n}$ of $\overline{X^*}$ converges to $w$ if and only if it is eventually stationary at $w$, or

$$w = \infty \quad \text{and} \quad \lim_{n} r_\mathcal{I}(w) = \infty$$

(i.e., the sequence $(w_n)_{n}$ "falls further and further down in $\mathcal{I}$").

If $\mathcal{I}$ is an ideal filtration, then one can verify that $\overline{X^*}$ is a topological monoid (the multiplications in $\overline{X^*}$ is a continuous function). Furthermore,
for each \( k \geq 0 \), \( \bar{X}^*/(I_k \cup \{\infty\}) \) is a monoid, and if this monoid is endowed
with the discrete topology, then the projection \( \pi_k : \bar{X}^* \to \bar{X}^*/(I_k \cup \{\infty\}) \)
is a continuous morphism.

For any filtration \( \mathcal{I} \) on \( X^* \), one can defined a ultrametric distance function \( d_{\mathcal{I}} \) on \( \bar{X}^* \) letting
\[
d_{\mathcal{I}}(w, w) = 0 \quad \text{for all } w \in \bar{X}^*,
\]
\[
d_{\mathcal{I}}(w, \infty) = \frac{1}{r_{\mathcal{I}}(w)} \quad \text{for all } w \in X^*, \quad \text{and}
\]
\[
d_{\mathcal{I}}(w_1, w_2) = \max (d_{\mathcal{I}}(w_1, \infty), d_{\mathcal{I}}(w_2, \infty))
\]
for all distinct \( w_1, w_2 \) in \( X^* \).

Note that, for all \( n \geq 1 \) and \( w_1 \neq w_2 \) in \( X^* \), we have
\[
d(w_1, w_2) < 1/n \iff w_1, w_2 \in I_n.
\]
For \( w \in \bar{X}^* \) and \( \varepsilon > 0 \), let \( B(w, \varepsilon) \) be the open ball with center \( w \) and
radius \( \varepsilon \). Then we have
\[
B(\infty, \varepsilon) = I_n \cup \{\infty\} \quad \text{where } n = \min \left\{ k \mid \frac{1}{k} < \varepsilon \right\}
\]
and for \( w \in X^* \)
\[
B(w, \varepsilon) = \begin{cases} 
\{w\} & \text{if } \varepsilon \leq \frac{1}{r_{\mathcal{I}}(w)} \\
B(\infty, \varepsilon) = I_n \cup \{\infty\} & \text{where } n = \min \left\{ k \mid \frac{1}{k} < \varepsilon \right\}, \\
& \text{if } \varepsilon > \frac{1}{r_{\mathcal{I}}(w)}.
\end{cases}
\]
Therefore, the topology induced by \( d_{\mathcal{I}} \) on \( \bar{X}^* \) is exactly \( \text{Top}_{\mathcal{I}} \).

3.2. Sequences of languages

We will be interested in languages of \( X^* \) which are limits in a certain
sense of a sequence of languages with respect to a given filtration \( \mathcal{I} \) on
\( X^* \). More precisely, the metric \( d_{\mathcal{I}} \) induces a Hausdorff metric on the set of
closed subsets of \( \bar{X}^* \): if \( L \) and \( L' \) are closed subsets of \( \bar{X}^* \), then \( D_{\mathcal{I}}(L, L') \)
is defined by
\[
D_{\mathcal{I}}(L, L') = \min\{\varepsilon > 0 \mid \forall w \in L, \exists w' \in L', d_{\mathcal{I}}(w, w') < \varepsilon \text{ and} \forall w' \in L', \exists w \in L, d_{\mathcal{I}}(w, w') < \varepsilon \}.
\]
Note that a set \( L \subseteq X^* \) is closed if and only if \( \infty \in L \) or \( L \subseteq X^* \setminus I_n \) for some \( n \geq 0 \). In particular, if \( L \subseteq X^* \), then \( L \cup \{\infty\} \) is always closed, and the closure of \( L \) is either \( L \) or \( L \cup \{\infty\} \).

If \( (L_n)_n \) is a sequence of languages of \( X^* \) and \( L \subseteq X^* \), we will write \( L = \lim_{\uparrow} L_n \) if \( L \cup \{\infty\} \) is the limit of the sequence of closed spaces \((L_n \cup \{\infty\})_n\), that is, if

\[
\lim_{n} D_I (L_n \cup \{\infty\}, L \cup \{\infty\}) = 0.
\]

One can verify the following proposition.

**Proposition 3.1:** Let \( L, L_n \subseteq X^* \) and let \( I = (I_n)_n \) be a filtration on \( X^* \). Then

\[
L = \lim_{\uparrow} L_n \text{ if and only if } \forall n, \exists k \geq 0, \forall m \geq k, L_m \setminus I_n = L \setminus I_n.
\]

**Example:** Let \( L \subseteq X^* \) and let \( I_n \ (n \geq 0) \) be the set of all words of length greater than or equal to \( n \). Let \( L_n = L \setminus I_n \) for each \( n \geq 0 \), and let \( I = (I_n)_n \). Then \( I \) is a cofinite ideal filtration, each \( L_n \) is finite and \( L = \lim_{\uparrow} L_n \).

Note the following easy property of this topology on the set of languages.

**Proposition 3.2:** Let \( I \) be a filtration on \( X^* \) and let \( (L_n)_n \) be a Cauchy sequence of languages over \( X \) (meaning that the sequence of closed subsets of \( X^* \) \((L_n \cup \{\infty\})_n\) is Cauchy for \( D_I \)). Then \( (L_n)_n \) is a convergent sequence.

**Proof:** Our hypothesis on \((L_n)_n\) is the following:

\[
\forall n \geq 1, \exists k \geq 1, \forall m \geq k, \quad L_m \setminus I_n = L_k \setminus I_n.
\]

We may then choose an increasing sequence of integers \((k_n)_n\) such that for all \( m \geq k_n \), we have \( L_m \setminus I_n = L_{k_n} \setminus I_n \). In particular, \( L_{k_n} \setminus I_n \subseteq L_{k_{n+1}} \setminus I_{n+1} \).

Let now \( L = \bigcup_{n} L_{k_n} \setminus I_n \). It is easy to verify that \( L \setminus I_n = L_{k_n} \setminus I_n \) for all \( n \) and hence that \( L = \lim_{\uparrow} I_n \). \( \square \)

In the sequel we will use the following notion. We say that a filtration \( I = (I_n)_n \) is **fast** if

\[
\forall w \in X^*, \exists k \geq 0, \forall n \geq 1, \quad w^n \notin I_k.
\]

**Example:** Let \( X = \{a, b\} \), let \( I_0 = X^* \), and let \( I_n = X^*a^n bX^* \) for all, \( n \geq 1 \). Then \( I = (I_n)_n \) is a fast rational ideal filtration. It is easy to verify
that \( I \) is a filtration. Suppose now that \( w^n \in I_k \) for some \( w \in X^* \), \( n \geq 3 \) and \( k \geq 1 \). Then \( a^k b \) is a factor of \( w^n \), and hence \( a^k b \) is a factor of \( w^2 \).

Since \( \bigcap I_n = \emptyset \), there exists \( k \) such that \( w \) and \( w^2 \) do not lie in \( I_k \). Then, for all \( n \geq 1 \), \( w^n \notin I_k \).

### 3.3. Sequences of automata

We now consider automata (with unspecified set of final states) over \( X \). The reader can consult Appendix 1 for a simpler version, stated for congruences instead of automata.

Recall that we assume all automata to be accessible, and that \( A(X) \) is the class of all (accessible) automata over \( X \) (see Section 1.1). To an automaton \( A = (Q, X, q_0, \lambda) \in A(X) \), we associate the equivalence relation

\[
C_A = \{(u, v) \in X^* \times X^* | q_0 \cdot u = q_0 \cdot v\}.
\]

Note that, for all \( u, v, w \in X^* \), if \( (u, v) \in C_A \), then \( (uw, vw) \in C_A \). That is, \( C_A \) is a right congruence of \( X^* \).

A morphism \( \varphi \) from \( A = (Q, X, q_0, \lambda) \in A(X) \) into \( A' = (Q', X, q'_0, \lambda') \in A(X) \) is a mapping \( \varphi : Q \to Q' \) such that, for all \( u \in X^* \), \( \lambda(q_0, u) \varphi = \lambda'(q'_0, u) \).

Thus, there exists a morphism from \( A \) to \( A' \) if and only if the equivalence relation \( C_A \) refines \( C_{A'} \). In that case, the morphism from \( A \) to \( A' \) is unique. Furthermore, since the automata we consider are accessible, the mapping \( \varphi \) is necessarily onto.

If \( A = (Q, X, q_0, \lambda) \) and \( A' = (Q', X', q'_0, \lambda') \) are in \( A(X) \), we define \( D_I(A, A') \) as follows (where \( \Delta \) denotes the symmetric difference).

\[
D_I(A, A') = \max \{d(u, v) | (u, v) \in C_A \Delta C_{A'} \} = \max \{d(u, v) | (q_0 \cdot u = q_0 \cdot v \text{ and } q'_0 \cdot u \neq q'_0 \cdot v) \text{ or } (q_0 \cdot u \neq q_0 \cdot v \text{ and } q'_0 \cdot u = q'_0 \cdot v) \}.
\]

Let us remark that \( D_I(A, A') = 0 \) if and only if \( C_A = C_{A'} \), that is, if and only if, for all \( u, v \in X^* \), \( q_0 \cdot u = q_0 \cdot v \) if and only if \( q'_0 \cdot u = q'_0 \cdot v \). Therefore, \( D_I(A, A') = 0 \) if and only if \( A \) and \( A' \) are isomorphic. In the next few lines we will verify that \( D_I \) is an ultrametric distance function on the set of isomorphism classes of automata over \( X \). It would be equivalent to define \( D_I \) directly on the set of right congruences of \( X^* \).
It suffices to verify that for all $A$, $B$ and $C$ in $A(X)$ we have
$D_T(A, C) \leq \max(D_T(A, B), D_T(B, C))$, which is an easy consequence of the containment

$$C_A \triangle C_C \subseteq (C_A \triangle C_B) \cup (C_B \triangle C_C).$$

Let $(A_n)_n$ and let $A$ be automata over $X$. We say that the sequence $(A_n)_n$ converges to $A$ (modulo $T$), and we write $A = \lim_n A_n$, if $\lim_n D_T(A_n, A) = 0$. From the above discussion, it follows that the limit of a convergent sequence of automata is unique up to isomorphism.

**Proposition 3.3:** Let $A = (Q, X, q_0, \lambda)$ and $A_n = (Q_n, X, q_0^n, \lambda_n)$ $(n \geq 0)$ be automata and let $\mathcal{I} = (I_n)_n$ be a filtration on $X^*$. Then

$$A = \lim_n A_n \text{ if and only if } \begin{cases} \forall n \geq 0, \exists k \geq 0, \forall m \geq k, \\ \forall u, v \in X^* \setminus I_n, \\ q_0^m \cdot u = q_0^m \cdot v \iff q_0 \cdot u = q_0 \cdot v. \end{cases}$$

**Proof:** This is immediate since we notice that, for all $n \geq 1$ and $u \neq v \in X^*$, $d(u, v) < 1/n$ if and only if both $n, v \in I_n$. $\square$

Let $(A_n = (Q_n, X, q_0^n, \lambda_n))_n$ be a sequence of automata. We say as usual that $(A_n)_n$ is a Cauchy sequence (modulo $\mathcal{I}$) if

$$\forall \varepsilon > 0, \exists k \geq 0, \forall n, m \geq k, D_I(A_n, A_m) < \varepsilon.$$ 

Equivalently, $(A_n)_n$ is a Cauchy sequence if and only if

$$\forall n \geq 0, \exists k_n \geq 0, \forall m \geq k_n, \forall u, v \in X^* \setminus I_n, q_0^{k_n} \cdot u = q_0^{k_n} \cdot v \iff q_0^m \cdot u = q_0^m \cdot v.$$ 

We have the following result, which is the analogue of Proposition 3.2.

**Proposition 3.4:** Let $(A_n = (Q_n, X, q_0^n, \lambda_n))_n$ be a sequence of automata over $X$ and let $\mathcal{I}$ be an ideal filtration on $X^*$. If $(A_n)_n$ is a Cauchy sequence modulo $\mathcal{I}$, then $(A_n)_n$ converge modulo $\mathcal{I}$.

**Proof:** For each $n \geq 0$, there exists $k_n \geq 0$ such that

$$\forall m \geq k_n, \forall u, v \in X^* \setminus I_n, q_0^{k_n} \cdot u = q_0^{k_n} \cdot v \iff q_0^m \cdot u = q_0^m \cdot v.$$
We may assume the sequence \((k_n)_n\) to be non-decreasing. For \(u, v \in X^*\), let us define \(u \sim v\) by

\[
  u \sim v \quad \text{if and only if for all } n \text{ such that } u, v \notin I_n, \quad q_0^{k_n} \cdot u = q_0^{k_n} \cdot v.
\]

This is equivalent to

\[
  u \sim v \quad \text{if and only if there exists } n \text{ such that } u, v \notin I_n \text{ and } q_0^{k_n} \cdot u = q_0^{k_n} \cdot v.
\]

We now verify that \(\sim\) is a right congruence. Let indeed \(u, v, w \in X^*\) and let us assume that \(u \sim v\). For each \(n\) such that \(uw, vw \notin I_n\), we have \(u, v \notin I_n\) (since \(I_n\) is an ideal) so \(q_0^{k_n} \cdot u = q_0^{k_n} \cdot v\) and hence \(q_0^{k_n} \cdot uw = q_0^{k_n} \cdot vw\).

We then define \(Q\) as the quotient set \(X^*/\sim\), we let \(\emptyset \in Q\) be the \(\sim\)-class of the empty word, and we define \(\lambda : Q \times X \to Q\) by \(\lambda ([u]_\sim, x) = [ux]_\sim\) for all \(u \in X^*\) and \(x \in X\). It is easy to verify that \(\lambda\) is well-defined, that \(A = (Q, X, q_0, \lambda) \in \mathcal{A}(X)\), and that \(A = \lim_\mathcal{I} A_n\).

Finally we will need the following notion. Let \(A = (Q, X, q_0, \lambda)\) and \(A_n = (Q_n, X, q_0^n, \lambda_n)(n \geq 0)\) be automata, and let \(\mathcal{I} = (I_n)_n\) be a filtration on \(X^*\). We say that the sequence \((A_n)_n\) **approximates** \(A\) **(modulo \(\mathcal{I}\))** if

\[
  \forall n \geq 0, \exists k_n \geq 0, \forall m \geq k_n, \quad
  \forall u, v \in X^* \setminus I_n, \quad q_0^m \cdot u = q_0^m \cdot v \Rightarrow q_0 \cdot u = q_0^m \cdot v.
\]

Quite clearly, if \((A_n)_n\) converges to \(A\), then \((A_n)_n\) approximates \(A\). However a given sequence \((A_n)_n\) may approximate several automata.

**Proposition 3.5:** Let \(A, B \) and \(A_n (n \geq 0)\) be automata over \(X\), and let \(\mathcal{I} = (I_n)_n\) be a filtration on \(X^*\) such that \(A = \lim_\mathcal{I} A_n\). Then \((A_n)_n\) approximates \(B\) modulo \(\mathcal{I}\) if and only if there exists a morphism \(\varphi : A \to B\).

**Proof:** Let us assume that the sequence \((A_n = (Q_n, X, q_0^n, \lambda_n))_n\) approximates \(B = (Q', X, q_0', \lambda')\). If \(A = (Q, X, q_0, \lambda)\), we need to verify that \(q_0 \cdot u = q_0 \cdot v\) implies \(q_0' \cdot u = q_0' \cdot v\) for all \(u, v \in X^*\). Let \(n \geq 0\) be such that \(u, v \notin I_n\). There exists integers \(k\) and \(k'\) such that, for each \(m \geq k\) (resp. \(m \geq k'\)) and for each \(x, y \in X^* \setminus I_n\), the equality \(q_0^m \cdot x = q_0^m \cdot y\) is equivalent to \(q_0 \cdot x = q_0 \cdot y\) (resp. implies \(q_0' \cdot x = q_0' \cdot y\)). By considering an integer \(m \geq \max(k, k')\), we find that \(q_0 \cdot u = q_0 \cdot v\) implies \(q_0' \cdot x = q_0' \cdot y\).

The converse implication is trivial. \(\Box\)

In the sequel, we will want to further qualify approximations. Let \(A = (Q, X, q_0, \lambda)\) and \(A' = (Q', X, q_0', \lambda')\) be automata, and let \(\varphi\) be a morphism from \(A\) to \(A'\). We say that \(\varphi\) is **torsion** (resp. **aperiodic**).
if, for each \( u \in X^* \) such that \( q' \cdot u = q' \cdot u^2 \) for all \( q' \in Q' \), there exists an integer \( k \) such that \( q \cdot u^k = q \cdot u^{2k} \) for all \( q \in Q \). Similarly, for a fixed integer \( k \), we say that \( \varphi \) is \( k \)-bounded torsion (resp. \( k \)-bounded aperiodic) if, for each \( u \in X^* \) such that \( q' \cdot u = q' \cdot u^2 \) for all \( q' \in Q' \), we have \( q \cdot u^k = q \cdot u^{2k} \) (resp. \( q \cdot u^k = q \cdot u^{k+1} \)) for all \( q \in Q \). Finally, \( \varphi \) is bounded torsion (resp. bounded aperiodic) if it is \( k \)-bounded torsion (resp. \( k \)-bounded aperiodic) for some \( k \).

Let now \( A, B \) and \( A_n \) \((n \geq 0)\) be automata over \( X \), let \( \mathcal{I} \) be a filtration on \( X^* \), and let us assume that \((A_n) \) converges to \( A \) and that \((A_n) \) approximates \( B \) modulo \( \mathcal{I} \). By Proposition 3.5, there exists a morphism \( \varphi \) from \( A \) to \( B \). We say that the approximation is torsion (resp. aperiodic, bounded torsion, bounded aperiodic) if the morphism \( \varphi \) is torsion (resp. aperiodic, bounded torsion, bounded aperiodic).

4. MAIN RESULTS

We will now state the main theorems of this paper. These results are generalizations of Kleene’s, Schützenberger’s and Straubing’s theorems and they characterize torsion, aperiodic, bounded torsion and bounded aperiodic languages. The first set of results deals with \( \mathcal{L}_{\text{tor}} \) and \( \mathcal{L}_{\text{ap}} \), and the second one deals with \( \mathcal{L}_{\text{tor}} \) and \( \mathcal{L}_{\text{ap}} \). The proofs of these theorems will be given in Section 5.

4.1. Bounded torsion and bounded aperiodic languages

Before we proceed with the results, let us mention a few important closure properties for a class of languages \( \mathcal{L} \). We say that

- \( \mathcal{L} \) satisfies (BT) if, for each \( L_1, L_2 \in \mathcal{L} \), we have \( BT(L_1, L_2) \subseteq \mathcal{L} \);
- \( \mathcal{L} \) satisfies (H\(^{-1}\)) if, for each morphism \( \varphi : X_1^* \rightarrow X_2^* \) between finitely generated free monoids and for each \( L \subseteq X_2^* \) in \( \mathcal{L} \), we have \( L \varphi^{-1} \subseteq \mathcal{L} \);
- \( \mathcal{L} \) satisfies (Pr) if, for each \( L, L' \subseteq X^* \) in \( \mathcal{L} \), we have \( LL' \in \mathcal{L} \);
- \( \mathcal{L} \) satisfies (St) if, for each \( L \in \mathcal{L} \), we have \( L^* \in \mathcal{L} \);
- \( \mathcal{L} \) satisfies (Lpq) if, for each prime \( p \), each integer \( 0 \leq q < p \) and each language \( L \in \mathcal{L} \), we have \((L, p, q) \in \mathcal{L} \).

Let \((L_n)\) be a sequence of languages over \( X \) and let \( \mathcal{I} = (I_n) \) be a filtration. Suppose that \( L = \lim_{\mathcal{I}} L_n \). We say that the limit is bounded if there exists \( k \geq 0 \) such that \( L_n \in \mathcal{L}_{\text{tor}}^{(k)} \) for each \( n \). It is bounded rational (resp. bounded rational subgroup-cyclic) if furthermore the \( L_n \) are rational (resp. bounded rational subgroup-cyclic).
rational subgroup-cyclic) for all $n$. We say that a class of languages $C$ is closed under bounded limits (resp. bounded rational limits, bounded rational subgroup-cyclic limits) if, whenever $L = \lim_{\tau} L_n$ and the limit is bounded (resp. bounded rational, bounded rational subgroup-cyclic) and $L_n \in C$ for each $n$, then $L \in C$.

**Theorem 4.1:** For each integer $k$, $L_{\text{btor}}^{(k)}$ satisfies (BT) and $(H^{-1})$ and is closed under limits. $L_{\text{btor}}$ satisfies (BT), $(H^{-1})$, (Pr) and (Lpq), and it is closed under bounded limits.

**Theorem 4.2:** For each integer $k$, $L_{\text{bap}}^{[k]}$ satisfies (BT) and $(H_{-1})$ and is closed under limits. $L_{\text{bap}}$ satisfies (BT), $(H^{-1})$ and (Pr), and it is closed under bounded limits.

**Caution:** It is important to note that, for any fixed $k$, $L_{\text{btor}}^{(k)}$ does not satisfy (Pr and Lpq), and that $L_{\text{bap}}^{[k]}$ does not satisfy (Pr). For instance, the product of two $k$-bounded torsion (resp. aperiodic) languages is bounded torsion (resp. aperiodic), but its torsion bound may be greater than $k$.

**Theorem 4.3:** Let $k \geq 1$, let $k' = \max(k, 4)$ and $L \subseteq X^*$. If $L \in L_{\text{btor}}^{(k)}$ (resp. $L \in L_{\text{bap}}^{[k]}$), then there exists a sequence $(L_n)_n$ and a fast ideal filtration $I = (I_n)_n$ such that $L = \lim_{\tau} L_n$ and $L_n$ and $I_n$ are rational (resp. star-free) and in $L_{\text{btor}}^{(k')}$ (resp. $L_{\text{bap}}^{[k']}$).

The above results yield immediately the following descriptions of $L_{\text{btor}}$ and $L_{\text{bap}}$, which generalize the theorems of Kleene and Schützenberger.

**Theorem 4.4:** (Bounded generalization of Kleene’s theorem) $L_{\text{btor}}$ is the least family of languages containing the rational languages and closed under bounded limits.

**Theorem 4.5:** (Bounded generalization of Schützenberger’s theorem) $L_{\text{bap}}$ is the least family of languages containing the star-free languages and closed under bounded limits.

Equivalently, $L_{\text{bap}}$ is the least family of languages containing the finite languages and closed under Boolean operations, product and bounded limits.

**Remark:** Theorems 4.1, 4.2 and 4.3 allow in fact more precise descriptions: $L_{\text{btor}}$ (resp. $L_{\text{bap}}$) is the least family of languages containing the rational (resp. star-free) languages and closed under bounded rational limits with respect to fast ideal bounded rational fibrations.
The following result, which is connected to Straubing's theorem on rational subgroup-solvable languages, is more surprising.

**Theorem 4.6:** Let \( k \geq 1 \), let \( k' = \max(k, 4) \) and \( L \subseteq X^* \). If \( L \in \mathcal{L}^{(k)}_{\operatorname{btor}} \), then there exists a sequence \( (L_n)_n \) and a fast ideal filtration \( \mathcal{I} = (I_n)_n \) such that \( L = \lim \mathcal{I} L_n \) and \( L_n \) and \( I_n \) are rational subgroup-cyclic and in \( \mathcal{L}^{(k')}_{\operatorname{btor}} \).

**Theorem 4.7:** (Bounded generalization of Straubing's theorem) \( \mathcal{L}_{\operatorname{btor}} \) is the least family of languages containing the finite languages, satisfying \( \text{(Lpq)} \) and closed under Boolean operations, product and bounded limits.

*Remark:* As above, Theorem 4.6 implies in fact a more precise statement: \( \mathcal{L}_{\operatorname{btor}} \) is the least family of languages containing the rational subgroup-cyclic languages and closed under bounded rational subgroup-cyclic limits with respect to fast ideal bounded rational subgroup-cyclic filtrations.

### 4.2. Torsion and aperiodic languages

In order to characterize the torsion and aperiodic languages in general, it is not sufficient to consider only limits of sequences of languages. In fact, as we noticed in Section 3.2, every language is the limit of a sequence of finite languages modulo a cofinite filtration.

A class of languages \( \mathcal{L} \) is *is closed under approximation* (resp. *under fast approximation*) if, for each filtration (resp. fast filtration), \( \mathcal{I} \), whenever an automaton \( A \) is approximated modulo \( \mathcal{I} \) by a sequence of automata \( (A_n)_n \) such that \( \mathcal{L}(A_n) \subseteq \mathcal{L} \) for all \( n \), then \( \mathcal{L}(A) \subseteq \mathcal{L} \).

**Theorem 4.8:** \( \mathcal{L}_{\operatorname{tor}} \) satisfies \( \text{(BT)}, \ (H^{-1}), \ (Pr), \ (St) \) and \( \text{(Lpq)} \), and is closed under fast approximation.

**Theorem 4.9:** \( \mathcal{L}_{\operatorname{ap}} \) satisfies \( \text{(BT)}, \ (H^{-1}) \) and \( \text{(Pr)} \), and is closed under fast approximation.

**Theorem 4.10:** Let \( A \) be an automaton over \( X \) such that \( \mathcal{L}(A) \subseteq \mathcal{L}_{\operatorname{tor}} \) (resp. \( \mathcal{L}(A) \subseteq \mathcal{L}_{\operatorname{ap}} \)). Then there exists a fast rational (resp. star-free) ideal filtration \( \mathcal{I} \) and a sequence of finite automata \( (A_n)_n \) (resp. such that \( \mathcal{L}(A_n) \subseteq \mathcal{L}_{\operatorname{ap}} \) for all \( n \)), such that \( (A_n)_n \) converges modulo \( \mathcal{I} \), \( (A_n)_n \) approximates \( A \) modulo \( \mathcal{I} \), and the approximation is bounded aperiodic.

As in Section 4.1, there results yield descriptions of \( \mathcal{L}_{\operatorname{tor}} \) and \( \mathcal{L}_{\operatorname{ap}} \) which generalize Kleene's and Schützenberger's theorems.
THEOREM 4.11: (Unbounded generalization of Kleene's theorem) \( \mathcal{L}_{\text{tor}} \) is the least family of languages containing the rational languages and closed under fast approximation.

Equivalently, \( \mathcal{L}_{\text{tor}} \) is the least family of languages containing the finite languages and closed under union, product, star and fast approximation.

THEOREM 4.12: (Unbounded generalization of Schützenberger's theorem) \( \mathcal{L}_{\text{ap}} \) is the least family of languages containing the star-free languages and closed under fast approximation.

Equivalently, \( \mathcal{L}_{\text{ap}} \) is the least family of languages containing the finite languages and closed under Boolean operations, product and fast approximation.

Remark: As above, we can in fact make these statement more precise: \( \mathcal{L}_{\text{tor}} \) (resp. \( \mathcal{L}_{\text{ap}} \)) is the least family of languages containing the rational (resp. star-free) languages and closed under fast bounded aperiodic approximation with respect to a fast rational (resp. star-free) ideal filtration.

Analogous to Theorem 4.6, we also have

THEOREM 4.13: Let \( A \) be an automaton over \( X \) such that \( \mathcal{L}(A) \subseteq \mathcal{L}_{\text{tor}} \) (resp. \( \mathcal{L}(A) \subseteq \mathcal{L}_{\text{ap}} \)). Then there exists a fast rational subgroup-cyclic ideal filtration \( \mathcal{I} \) and a sequence of finite automata \( (A_n)_n \) such that the languages recognized by the \( A_n \) are rational cyclic, \( (A_n)_n \) converges modulo \( \mathcal{I} \), \( (A_n)_n \) approximates \( A \) modulo \( \mathcal{I} \), and the approximation is aperiodic.

THEOREM 4.14: (Unbounded generalization of Straubing's theorem) \( \mathcal{L}_{\text{tor}} \) is the least family of languages containing the rational subgroup-cyclic languages and closed under fast approximation.

Equivalently, \( \mathcal{L}_{\text{tor}} \) is the least family of languages containing the finite languages, satisfying (Lpq) and closed under Boolean operations, product and fast approximation.

4.3. Arbitrary languages

The important Theorems 4.10 and 4.13 above are "fast" versions of results that hold for arbitrary automata, namely Theorems 4.15 and 4.16 below. Note that the latter differ from Theorems 4.10 and 4.13 only by the fact that the filtrations they involve need not be fast. As we will see in Section 5.2, the proofs of Theorems 4.10, 4.13, 4.15 and 4.16 are very similar.
Theorem 4.15: (Arbitrary language theorem) Let $A$ be an automaton over $X$. Then there exists a rational ideal filtration $\mathcal{I}$ and a sequence of finite automata $(A_n)_n$ such that $(A_n)_n$ converges modulo $\mathcal{I}$, $(A_n)_n$ approximates $A$ modulo $\mathcal{I}$, and the approximation is bounded aperiodic.

Theorem 4.16: (Cyclic arbitrary language theorem) Let $A$ be an automaton over $X$. Then there exists a rational subgroup-cyclic ideal filtration $\mathcal{I}$ and a sequence of finite automata $(A_n)_n$ such that the languages recognized by the $A_n$ are rational subgroup-cyclic, $(A_n)_n$ converges modulo $\mathcal{I}$, $(A_n)_n$ approximates $A$ modulo $\mathcal{I}$, and the approximation is aperiodic.

5. PROOFS OF THE MAIN RESULTS

The proofs of Theorems 4.1, 4.2, 4.8 and 4.9 can be obtained using more or less classical methods, and we shall give these proofs in Section 5.1. As for Theorems 4.3, 4.6, 4.10, 4.13, 4.15 and 4.16, their proofs is more delicate and requires some deep results of semigroup theory. These proofs will be discussed in Section 5.2. Finally, we note that given these theorems, the bounded and unbounded generalizations of Kleene’s, Schützenberger’s and Straubing’s theorems (Theorems 4.4, 4.5, 4.7, 4.11, 4.12 and 4.14) are immediate.

5.1. Proof of Theorems 4.1, 4.2, 4.8 and 4.9

First we observe that rational languages are trivially in $\mathcal{L}_{\text{btor}}$ and that aperiodic (star-free) rational languages are in $\mathcal{L}_{\text{ap}}$.

The fact that the families $\mathcal{L}_{\text{btor}}^{(k)}$, $\mathcal{L}_{\text{bap}}^{[k]}$, $\mathcal{L}_{\text{btor}}$, $\mathcal{L}_{\text{bap}}$, $\mathcal{L}_{\text{tor}}$ and $\mathcal{L}_{\text{ap}}$ satisfy (BT) is a direct consequence of Proposition 1.3, together with Lemma 1.2 and Proposition 2.3. The same Lemma 1.2 and Proposition 2.3 show that these classes of languages satisfy (H$^{-1}$).

Let us now show that they all satisfy (Pr), and that $\mathcal{L}_{\text{tor}}$ and $\mathcal{L}_{\text{btor}}$ satisfy (Lpq). The proof uses the properties of the Schützenberger product and of its “$\text{mod } p$”-variant. For more detail on these products, see in particular [15, 22, 23].

Proposition 5.1: $\mathcal{L}_{\text{btor}}$, $\mathcal{L}_{\text{bap}}$, $\mathcal{L}_{\text{tor}}$ and $\mathcal{L}_{\text{ap}}$ satisfy (Pr).

Proof: Let $L$ and $L'$ be languages in $X^*$, let $S(L)$ and $S(L')$ be their syntactic monoids, and let $\eta_L$ and $\eta_{L'}$ be their syntactic morphisms. Let $\eta$

Informatique théorique et Applications/Theoretical Informatics and Applications
be the morphism from \( X^* \) into the multiplicative monoid of \((2,2)\)-matrices with entries in the semiring \((\mathcal{P} S (L) \times S (L'), \cup, \cdot)\) defined by

\[
x\eta = \begin{pmatrix}
\{(x\eta_L, 1)\} \\
\emptyset
\end{pmatrix}
\begin{pmatrix}
\{(1, 1)\} \\
\{(1, x\eta_{L'})\}
\end{pmatrix}
\text{ for all } x \in X.
\]

One can check that, for all \( w \in X^* \), we have

\[
w\eta = \begin{pmatrix}
\{(w\eta_L, 1)\} \\
\emptyset
\end{pmatrix}
P_w
\begin{pmatrix}
\{(1, w\eta_{L'})\}
\end{pmatrix}
\]

where \( P_w = \{(w\eta_L, w\eta_{L'})|w = uv\} \). Then, \( LL' = K\eta^{-1} \), where \( K \) is the set of all matrices in the form

\[
\begin{pmatrix}
\{(s, 1)\} \\
\emptyset
\end{pmatrix}
P
\begin{pmatrix}
\{(1, s')\}
\end{pmatrix}
\]

with \( P \cap (L\eta_L \times L'\eta_{L'}) \neq \emptyset \). The range of \( \eta \) is denoted \( X^*\eta = \diamond_2 (S (L), S (L')) \) and is called the Schützenberger product of \( S (L) \) and \( S (L') \). Let now \( \pi \) be the morphism from \( \diamond_2 (S (L), S (L')) \) into \( S(L) \times S(L') \) defined by \( w\eta\pi = (w\eta_L, w\eta_{L'}) \). Let \( e \) and \( e' \) be idempotents, respectively in \( S (L) \) and \( S (L') \). Then the inverse image \((e, e')\pi^{-1} \) satisfies the identity \( x^3 = x^4 \). Let indeed \( m \in (e, e')\pi^{-1} \), say,

\[
m = \begin{pmatrix}
\{(e, 1)\} \\
\emptyset
\end{pmatrix}
P
\begin{pmatrix}
\{(1, e')\}
\end{pmatrix}
\]

Then, for each \( n \geq 1 \), \( m^n \) is in the form

\[
m^n = \begin{pmatrix}
\{(e, 1)\} \\
\emptyset
\end{pmatrix}
P_n
\begin{pmatrix}
\{(1, e')\}
\end{pmatrix}
\]

where \( P_1 = P \) and \( P_{n+1} = (e, 1) P \cup P_n (1, e') \). In particular

\[
P_2 = (e, 1) P \cup P (1, e')
\]

\[
P_3 = (e, 1) P \cup (e, 1) P (1, e') \cup P (1, e')
\]

\[
P_n = P_3 \text{ for all } n \geq 3.
\]

Therefore \( \pi \) is a bounded aperiodic morphism and hence (see Proposition 2.2), if \( S (L) \) and \( S (L') \) are in \textbf{Tor}, \textbf{bTor}, \textbf{Ap} or \textbf{bAp}, then so are \( \diamond_2 (S (L), S (L')) \) and \( S (LL') \). \( \square \)
PROPOSITION 5.2: \( L_{\text{btor}} \) and \( L_{\text{tor}} \) satisfy \((Lpq)\).

Proof: The proof is quite similar to the proof of Proposition 5.1. Let \( p \) be a prime number, let \( L \) be a language in \( X^* \), and let \( \eta_L : X^* \to S(L) \) be its syntactic morphism. Let \( \eta \) be the morphism from \( X^* \) into the multiplicative monoid of \((2,2)\)-matrices with entries in the semiring \( \mathbb{Z}_p [S(L)] \) defined by

\[
x \eta = \begin{pmatrix} x \eta_L & 1 \\ 0 & 1 \end{pmatrix}
\]

for all \( x \in X \).

\( \mathbb{Z}_p [S(L)] \) is the semiring of formal linear combinations of elements of \( S(L) \) with coefficients in the cyclic group of order \( p \), \( \mathbb{Z}_p \). (Note that the semiring \((P(S), \cup, \cdot)\) can be identified with \( B[S] \) where \( B \) is the Boolean semiring.)

One can check that, for all \( w \in X^* \), we have

\[
w \eta = \begin{pmatrix} w \eta_L & P_w \\ 0 & 1 \end{pmatrix}
\]

with \( P_w = \sum u \eta_L \) where the sum runs over all prefixes \( u \) of \( w \). Then \( \eta \) recognizes \( (L, p, q) \). Indeed, if \( K \) is the set of matrices of the form

\[
\begin{pmatrix} s & P \\ 0 & 1 \end{pmatrix}
\]

with \( P = \sum_{s \in S(L)} c_s s \) with \( \sum_{s \in L \eta_L} c_s \equiv q \, (\text{mod} \, p) \), then \( (L, p, q) = K \eta^{-1} \).

The range of \( \eta \) is denoted \( X^* \eta = \mathbb{Z}_p \diamond_2 (S(L), 1) \). Let now \( \pi \) be the morphism from \( \mathbb{Z}_p \diamond_2 (S(L), 1) \) into \( S(L) \) defined by \( w \eta \pi = w \eta_L \). Let \( e \) be idempotent of \( S(L) \) and let \( m \in e \pi^{-1} \), that is,

\[
m = \begin{pmatrix} e & P \\ 0 & 1 \end{pmatrix}
\]

Then, one verifies by induction that for each \( n \geq 1 \),

\[
m^n = \begin{pmatrix} e & (n-1)P + P \\ 0 & 1 \end{pmatrix}
\]

Therefore \( m^{p+1} = m \) and hence \( \pi \) is a bounded torsion morphism. By Proposition 2.2, if \( S(L) \) is torsion (resp. bounded torsion), then so are \( \mathbb{Z}_p \diamond_2 (S(L), 1) \) and \( S((L, p, q)) \). \( \square \)
Remark: Let $L_0, L_1, \ldots, L_k \subseteq X^*$, $a_1, \ldots, a_k \in X$ and $r \geq 0$, $n \geq 2$. We define the product with counter $(L_0 a_1 L_1 \ldots a_k L_k)_{r,n}$ to be the set of all words $w \in X^*$ for which the number of factorizations in the form

$$w = w_0 a_1 \ldots a_k w_k \quad \text{with } w_i \in L_i \quad \text{for } 0 \leq i \leq k$$

is congruent to $r$ modulo $n$. This product was studied in detail in [22, 23], and the above proof shows in fact that $\mathcal{L}_{\text{btor}}$ and $\mathcal{L}_{\text{tor}}$ are closed under such products.

Our next task will be to prove the following result. Our proof extends ideas contained in the proof of a less general result, due to Straubing [21].

**Proposition 5.3:** $\mathcal{L}_{\text{tor}}$ satisfies (St).

**Proof:** Let $L \subseteq X^*$ be a torsion language and let $\eta_L : X^* \rightarrow S(L)$ be its syntactic morphism. Let $w \in X^*$. Then there exists $n \geq 1$ such that $w^n \eta_L = w^{2n} \eta_L$. Let $x = w^n$. Then $x \eta_L = x^2 \eta_L$. It will be sufficient to prove that there exist $k$ and $k' \geq 1$ such that $x^k \eta_L x^{k'} = x^{k+k'} \eta_L x^{k'}$.

Let $k_1 = 2 + 4|x|$ and $k_2 = (k_2 - 2)!$. We will first prove that, for all $u, v \in X^*$,

$$ux^{k_1}v \in L^* \quad \Rightarrow \quad ux^{k_1+k_2}v \in L^*,$$

$$ux^{k_1}v \in L^* \quad \Rightarrow \quad \exists 1 \leq t \leq k_1 - 2, \ ux^{k_1-t}v \in L^*.$$

Indeed, if $ux^{k_1}v \in L^*$, then $ux^{k_1}v = x_1 \ldots x_p$ for some $x_1, \ldots, x_p \in L$. For each $0 \leq r \leq 1 + 2|x| = k_1/2$, let

$$i_r = \min \{1 \leq i \leq p | u x^{2r} \text{ is a prefix of } x_1 \ldots x_i\}.$$

Then $r \mapsto i_r$ is a non-decreasing function from $\{0, \ldots, 1 + 2|x|\}$ into $\{1, \ldots, p\}$. If the function $r \mapsto i_r$ is not injective, then there exists $0 \leq r \leq 2|x|$ such that $i_r = i_{r+1}$, that is, $ux^{2r} = x_1 \ldots x_{i_r-1} u'$ and $x_1 \ldots x_{i_r} = ux^{2(r+1)} u'$ for some non-empty prefix $u'$ of $x_{i_r}$ and for some $v' \in X^*$. In particular $x_{i_r} = u' x^{2} u'$ and $v' x_{i_r+1} \ldots x_p = x^{k_1-2(r+1)} v$. Since $x \eta_L = x^2 \eta_L = x^t \eta_L$ for all $t \geq 1$, we have $u' x v' \in L$ and $u' x^{2+t} u' \in L$ for all $t \geq 1$. Therefore

$$ux^{k_1-1}v = ux^{2r} xx^{k_1-2(r+1)} u = x_1 \ldots x_{i_r-1} (u' x v') x_{i_r+1} \ldots x_p \in L^*$$
and, for \( t \geq 1 \)
\[
ux^{k_1+t}v = u x^{2^t x^{k_1-2 (r+1)} u} = x_1 \ldots x_{i_r-1} (u' x^{2^t u'}) x_{i_r+1} \ldots x_p \in L^*.
\]

Now, if the function \( r \mapsto i_r \) is injective, then for each \( 0 \leq r \leq 2|x| \), we have
\[
x_1 \ldots x_{i_r} = u x^{2^r w_1 (r)} \quad x_{i_r+1} \ldots x_p = w_2 (r) x^{k_1-2 (r+1)} v
\]
for some words \( w_1 (r) \) and \( w_2 (r) \) such that \( w_1 (r) w_2 (r) = x^2 \) and \( w_2 (r) \neq 1 \).

Since \( r \) can assume \( 2|x| + 1 \) values, there exists \( 0 \leq r \leq r' \leq 2|x| \) such that \( w_1 (r) = w_1 (r') \) and \( w_2 (r) = w_2 (r') \).

Therefore
\[
ux^{k_1-2 (r'-r)} v = ux^{2^r w_1 (r) w_2 (r') x^{k_1-2 (r+1)} v} = x_1 \ldots x_{i_r} x_{i_r+1} \ldots x_p \in L^*,
\]
and, since \( x_{i_r+1} \ldots x_{i_r} = w_2 (r) x^{2 (r'-r-1)} w_1 (r') \), for all \( t \geq 1 \) we have
\[
ux^{k_1+2t (r'-r)} v = ux^{2^r w_1 (r) (w_2 (r) x^{2 (r'-r-1)} w_1 (r'))^t} x^{k_1-2 (r+1)} v = x_1 \ldots x_{i_r} (x_{i_r+1} \ldots x_i)^t x_{i_r+1} \ldots x_p \in L^*.
\]

Note that \( 2 (r' - r) \leq 2r' \leq 4|x| \leq k_1 - 2 \). Therefore, in all cases and if \( k_2 = (k_1 - 2)! \),
\[
ux^{k_1 v} \in L^* \Rightarrow ux^{k_1+k_2 v} \in L^*,
\]
\[
ux^{k_1 v} \in L^* \Rightarrow ux^{k_1-t v} \in L^* \quad \text{for some} \ 1 \leq t \leq k_1 - 2.
\]

Let now \( y = x^{k_2} \) and \( k_3 = 2 + 4|y| \). Since \( y \eta_L = y^2 \eta_L \), the above computation shows that
\[
uy^{k_3} v \in L^* \Rightarrow uy^{k_3-t} v \in L^* \quad \text{for some} \ 1 \leq t \leq k_3 - 2,
\]
that is,
\[
ux^{k_2 k_3 v} \in L^* \Rightarrow ux^{(k_3-t) k_2 v} \in L^* \quad \text{for some} \ 1 \leq t \leq k_3 - 2.
\]
Now, \((k_3 - t)k_2 \geq 2k_2 \geq k_1\), so that

\[ux^{(k_3-t)}k_2v \in L^* \implies ux^{(k_3-t)+sk_2}v \in L^* \text{ for all } s \geq 1\]

and hence

\[ux^{k_2k_3}v \in L^* \implies ux^{k_2k_3-k_2}v \in L^*.

Conversely, since \(k_2k_3 - k_2 \geq k_1\),

\[ux^{k_2k_3-k_2}v \in L^* \implies ux^{k_2k_3}v \in L^*.

Therefore \(x^{k_2k_3-k_2}\eta_{L^*} = x^{k_2k_3}\eta_{L^*}\), which concludes the proof. \(\square\)

The following proposition will help us show that \(\mathcal{L}_{\text{btor}}^{(k)}\) and \(\mathcal{L}_{\text{bap}}^{[k]}\) are closed under limits.

**Proposition 5.4:** Let \(\mathcal{I} = (I_n)_n\) be a filtration of \(X^*\) and let \(L \subseteq X^*\) be the limit \(L = \lim_{\mathcal{I}} L_n\) for some sequence of languages \((L_n)_n\). Then \(S(L) \leq \prod_n S(L_n)\).

**Proof:** Let \(\eta_n : X^* \to S(L_n)\) be the syntactic morphism of \(L_n\) and let \(\eta : X^* \to \prod_n S(L_n)\) be defined by \(u\eta = (u\eta_n)_n\) for all \(u \in X^*\). By Lemma 1.2, it suffices to show that \(\eta\) recognizes \(L\). Let us assume that \(u, v \in X^*\) are such that \(u\eta = v\eta\) and \(u \in L\). Since \(\bigcap_n I_n = \emptyset\), there exists \(n_0 \geq 1\) such that \(u\) and \(v\) are not in \(I_{n_0}\). Since \(L = \lim_{\mathcal{I}} L_n\), there exists \(n_1\) such that \(L \setminus I_{n_0} = L_{n_1} \setminus I_{n_0}\). In particular, \(u \in L_{n_1}\). But \(u\eta = v\eta\) implies \(u\eta_{n_1} = v\eta_{n_1}\), so \(v \in L_{n_1} \setminus I_{n_0}\) and hence \(v \in L\). Thus \(\eta\) recognizes \(L\). \(\square\)

**Corollary 5.5:** For all \(k\), the classes \(\mathcal{L}_{\text{btor}}^{(k)}\) and \(\mathcal{L}_{\text{bap}}^{[k]}\) are closed under limits. In particular, \(\mathcal{L}_{\text{btor}}\) and \(\mathcal{L}_{\text{bap}}\) are closed under bounded limits.

**Proof:** We known that the classes \(\mathcal{Btor}_k\) and \(\mathcal{BAP}_k\) are closed under arbitrary direct product and taking finitely generated divisors. In particular, if \(\mathcal{I}\) is a filtration of \(X^*\) and if \(L = \lim_{\mathcal{I}} L_n\) where the \(L_n\) are all in \(\mathcal{L}_{\text{btor}}^{(k)}\) (resp. \(\mathcal{L}_{\text{bap}}^{[k]}\)), then so is \(L\). This shows immediately that the classes \(\mathcal{L}_{\text{btor}}\) and \(\mathcal{L}_{\text{bap}}\) satisfy the required closure property. \(\square\)

To complete this section we prove the following important proposition.

**Proposition 5.6:** Let \(\mathcal{L}_{\text{tor}}\) and \(\mathcal{L}_{\text{ap}}\) are closed under fast approximation.
Proof: Let \( \mathcal{I} = (I_n)_n \) be a fast filtration, and let \( A = (Q, X, q_0, \lambda) \) and \( A_n = (Q_n, X, q_0^n, \lambda_n) \) \((n \geq 0)\) be automata such that \( \mathcal{L}(A_n) \subseteq \mathcal{L}_{tor} \) for all \( n \) and such that the sequence \((A_n)_n\) approximates \( A \) modulo \( \mathcal{I} \). By Proposition 2.5, we known that \( S(A_n) \in \text{Tor} \) for each \( n \), and we need to show that \( S(A) \in \text{Tor} \).

Let \( u \in X^* \). Since \( \mathcal{I} \) is a fast filtration, there exists an integer \( n \) such that \( u^* \cap I_n = \emptyset \). Let now \( k_n \) be the integer associated to \( n \) in the definition of approximation. Since \( S(A_n) \in \text{Tor} \), there exists \( r \geq 1 \) such that \( q \cdot u^r = q \cdot u^{2r} \) for all \( q \in Q_{k_n} \). This is equivalent to \( q_0^{k_n} \cdot vu^r = q_0^{k_n} \cdot vu^{2r} \) for all \( v \in X^* \). Because of the way we chose \( k_n \), this implies \( q_0 \cdot vu^r = q_0 \cdot vu^{2r} \) for all \( v \in X^* \), and hence \( q \cdot u^r = q \cdot u^{2r} \) for all \( q \in Q \). Thus \( S(A) \) is torsion and hence \( \mathcal{L}(A) \subseteq \mathcal{L}_{tor} \).

The proof of the statement concerning \( \mathcal{L}_{ap} \) is similar. \( \square \)

5.2. Proof of Theorems 4.3, 4.6, 4.10, 4.13, 4.15 and 4.16

These proofs require three deep results from semigroup theory. The first of these results (Theorem 5.7 below) is a property of finitely generated Burnside monoids, defined by identities of the form \( x^k = x^{k+1} \). This result was first proved by McCammond [11] for \( k \geq 6 \), and extended to \( k \geq 4 \) by Pereira do Lago [14] using different methods. The two other results are properties of the semigroup expansions \( S \mapsto \bar{S}^{(3)} \) and \( S \mapsto \bar{S} \) (cut-down to generators) considered by Rhodes and others. A complete study of these expansions, including the proof of the results stated here, can be found in the works of Birget, Henckell, Lazarus and Rhodes [1, 17, 18, 6]. See also Appendix 2 below.

**Theorem 5.7:** (See [11, 14]) Let \( X \) be a finite alphabet, and let \( k \) and \( l \) be integers with \( k \geq 4 \) and \( l \geq 1 \). Let \( B_X(k, l) \) be the monoid generated by \( X \) and defined by the identity \( x^k = x^{k+1} \).

1. The maximal subgroups of \( B_X(k, l) \) are finite cyclic groups.
2. There exists a sequence \((J_n)_n\) of ideals of \( B_X(k, l) \) such that

\[
\bigcap_n J_n = \emptyset, \text{ and } B_X(k, l)/J_n \text{ is a finite monoid.}
\]

**Theorem 5.8:** (See [1]) Let \( S \) be a finitely generated semigroup, and let \( \sigma : X^* \rightarrow S \) be an onto morphism, with \( X \) a finite alphabet. There exists
a semigroups $\hat{S}(3)$, an onto morphism $\tau : X^* \to \hat{S}(3)$ and a morphism $\pi : \hat{S}(3) \to S$ which satisfy the following property

1. $\tau \pi = \sigma$.
2. $\pi$ is a 5-bounded-aperiodic morphism.
3. The subgroups of $\hat{S}(3)$ are isomorphic to the finite subgroups of $S$.
4. There exists a sequence
   $(J_n)_n$ of ideals of $\hat{S}(3)$ such that
   
   \[ \hat{S}(3) = J_0 \supseteq J_1 \supseteq \ldots \supseteq J_n \supseteq \ldots \]

   $\bigcap_n J_n = \emptyset$, and $\hat{S}(3)/J_n$ is a finite monoid.

**Theorem 5.9:** (See [17, 18]) Let $S$ be a finitely generated semigroup, and let $\sigma : X^* \to S$ be an onto morphism, with $X$ a finite alphabet. There exists a semigroup $\overline{S}$, an onto morphism $\sigma : X^* \to \overline{S}$ and a morphism $\psi : \overline{S} \to S$ which satisfy the following property

1. $\varphi \psi = \sigma$.
2. $\psi$ is an aperiodic morphism.
3. The maximal subgroups of $\overline{S}$ are finite cyclic groups.

We are now ready to give the remaining proofs.

**Proof of Theorems 4.3 and 4.6:** Let $L \subseteq X^*$ and let $\sigma : X^* \to S$ be its syntactic morphism. If $L \in L_{btor}$, then $S \in bTor$, and hence $S \in bTor_k$ for some integer $k$. Since $k \leq k'$, $S$ belongs to $bTor_{k'}$ as well. Let $\mu$ be the canonical morphism from $X^*$ onto $B_X (k', k')$. Then there exists an onto morphism $\varphi : B_X (k', k') \to S$ such that $\mu \varphi = \sigma$. Let $(J_n)_n$ be given by Theorem 5.7 and let $I_n = J_n \mu^{-1}$ for each $n \geq 0$.

$I = (I_n)_n$ is trivially an ideal filtration on $X^*$. Furthermore, each $I_n$ is recognized by the morphism $\mu_n : X^* \to B_X (k', k')/J_n$ obtained by composing $\mu$ with the canonical projection of $B_X (k', k')$ onto $B_X (k', k')/J_n$.

This proves that $I_n$ is rational subgroup-cyclic and $k$-bounded-torsion. The fact that $B_X (k', k')$ is torsion also implies that $I$ is a fast filtration. Indeed for each $w \in X^*$, the set $w^* \mu$ is finite, so there exists $n \geq 1$ such that $w^* \mu \cap J_n = \emptyset$ and hence $w^* \cap J_n = \emptyset$.

Let now $L_n = L \setminus I_n$ for each $n \geq 0$. Since $L$ is recognized by $\sigma$, it is recognized by $\mu$ too, and hence $L_n$ is recognized by the morphism $\mu_n$, so that $L_n$ is rational subgroup-cyclic and $k'$-bounded-torsion for all $n$. It
is then easy to verify that \( L = \lim_{\mathcal{I}} I_n \) and the limit is bounded rational subgroup-cyclic.

In the case where \( L \in \mathcal{L}_{\mathcal{bap}}^{[k]} \), we have \( S \in \mathcal{bAp}_k \), and we consider \( B_X (k', 1) \) instead of \( B_X (k', k') \). The corresponding statement of Theorem 4.3 follows since \( B_X (k', 1) \in \mathcal{bAp}_k \) by Theorem 5.7. \( \square \)

Proof of Theorem 4.15: Let \( A = (Q, X, q_0, \lambda) \) be an automaton and let \( \sigma : X^* \rightarrow S = S (A) \) be its transition morphism. Let also \( \tau : X^* \rightarrow \hat{S}^{(3)} \), \( \pi : \hat{S}^{(3)} \rightarrow S \) and \((J_n)_{n} \) be given by Theorem 5.8 and let \( I_n = J_n \tau^{-1} \) for each \( n \geq 0 \). As in the above proof, one verifies that, for each \( n \), \( I_n \) is recognized by the onto morphism \( \tau_n : X^* \rightarrow \hat{S}^{(3)}/J_n \), obtained by composing \( \tau \) with the projection of \( \hat{S}^{(3)} \) onto \( \hat{S}^{(3)}/J_n \). Note that \( \hat{S}^{(3)}/J_n \) is finite. So \( \mathcal{I} = (I_n)_{n} \) is a rational ideal filtration. For each \( n \), let \( A_n = A (\hat{S}^{(3)}/J_n) \) be the automaton associated with the morphism \( \tau_n \). It is not difficult to verify that the sequence \((A_n)_{n} \) converges to \( A ^{\Delta (3)} \) modulo \( \mathcal{I} \). Furthermore

\[
\varphi : \hat{S}^{(3)} \rightarrow Q
\]

\[
u \tau \mapsto q_0 \cdot u
\]

is a well-defined morphism from \( A (\hat{S}^{(3)}) \) to \( A \), so that the sequence \((A_n)_{n} \) approximates \( A \) modulo \( \mathcal{I} \) (Proposition 3.5). There remains to verify that the approximation is bounded aperiodic. Let \( u \in X^* \) be such that \( q \cdot u = q \cdot u^2 \) for all \( q \in Q \). Then \( u \sigma = u^2 \sigma \) and hence \( u^3 \tau = u^6 \tau \) since \( \pi : \hat{S}^{(3)} \rightarrow S \) is 5-bounded aperiodic. Therefore, if \( s \) is any state of \( A (\hat{S}^{(3)}) \), then \( s \cdot u^3 = s (u^3 \tau) = s (u^6 \tau) = s \cdot u^6 \). This concludes the proof. \( \square \)

Proof of Theorem 4.10: The proof of Theorem 4.15 given above can be copied verbatim. We only need to verify that the filtration \( \mathcal{I} \) is fast, and that the \( I_n \) and the languages of the \( A_n \) are star-free if \( \mathcal{L} (A) \subseteq \mathcal{L}_{\mathcal{ap}} \). Since \( \pi \) is 5-bounded-aperiodic, \( \hat{S}^{(3)} \) is torsion (resp. aperiodic) if \( S \) is, that is, if \( \mathcal{L} (A) \subseteq \mathcal{L}_{\mathcal{ap}} \), then the monoids \( \hat{S}^{(3)}/J_n \) are finite and aperiodic, so that \( I_n \) and the languages of \( A_n \) are star-free. The proof that \( \mathcal{I} \) is fast is as in the proof of Theorem 4.3. \( \square \)

Proof of Theorem 4.16: This proof is quite similar to the proof of Theorem 4.15. Let \( A = (Q, X, q_0, \lambda) \) be an automaton and let \( \sigma : X^* \rightarrow S = S (A) \) be its transition morphism. Let \( \varphi : X^* \rightarrow \overline{S} \) and \( \psi : \overline{S} \rightarrow S \) be given by Theorem 5.9. We now apply Theorem 5.8 to the morphism \( \varphi \). Let \( T = \overline{S}^{\Delta (3)} \). We obtain onto morphism \( \tau : X^* \rightarrow T \),
\[ \pi : T \to \overline{S} \] and a sequence \((J_n)_n\) of ideals of \(T\). Let now \(\mathcal{I} = (I_n)_n\) with \(I_n = J_n\pi^{-1}\) for all \(n \geq 0\). Reasoning as in the proof of Theorem 4.15, we verify that each \(I_n\) is recognized by a morphism \(\tau_n : X^* \to T/J_n\), which proves that \(I_n\) is rational subgroup-cyclic. Again, we verify that, if \(A_n = A(T/J_n)\), the sequence \((A_n)_n\) converges to \(A(T)\) modulo \(\mathcal{I}\), and there exists a torsion morphism from \(A(T)\) to \(A\). Thus \((A_n)_n\) approximates \(A\) modulo \(\mathcal{I}\) and the approximation is aperiodic. 

**Proof of Theorem 4.13:** We only need to complete the proof of Theorem 4.16 with the consequences of the fact that \(\mathcal{L}(A) \subseteq \mathcal{L}_{\text{tor}}\), that is, \(S \in \text{Tor}\), and this is done as in the proof of Theorem 4.10. 

**Appendix 1: Sequences of morphisms**

Instead of considering sequences of automata as we did in Section 3.3, we could have considered of \(X\)-generated monoids, or more precisely, of onto morphisms defined on \(X^*\). To such a morphism \(\sigma : X^* \to S\) we associate the congruence

\[ C_\sigma = \{(u, v) \in X^* \times X^* | u\sigma = v\sigma\}. \]

Given a filtration \(\mathcal{I}\) on \(X^*\), we then define a distance function \(D_\mathcal{I}\) by

\[ D_\mathcal{I}(\sigma, \tau) = \max \{d(u, v) | (u, v) \in C_\sigma \Delta C_\tau\}. \]

As in Section 3.3, \(D\) is in fact a distance function on the set of isomorphism classes of onto morphisms defined on \(X^*\), which is ultrametric. Results analogous to Propositions 3.3 to 3.5 hold for this metric too. In particular, one can define the concept of a sequence of onto morphisms approximating an onto morphism modulo a filtration, and the concept of a class of monoids being closed under (fast) approximation.

Within this framework, statements similar to those of Sections 4.2 and 4.3 hold, and they are obtained with proofs quite similar to those reported for Proposition 5.6 and in Section 5.2.

**Appendix 2: Rational filtration associated to an arbitrary congruence**

Let \(\equiv\) be an arbitrary congruence on \(X^*\) and let \(\sigma : X^* \to S = X^*/\equiv\) be the canonical projection morphism. In this section we will show how a rational ideal filtration is naturally associated with \(\equiv\). Let us emphasize that \(\equiv\) is arbitrary but that the (simple) objects which we construct from \(\equiv\)-computations are rational!
Recall the definition of Green's relation $\mathcal{J}$. If $s$ and $t$ are elements of a monoid $S$, we say that $s \leq \mathcal{J} t$ if $SsS \subseteq StS$ and that $s \mathcal{J} t$ if $SsS = StS$. Then $\mathcal{J}$ is an equivalence relation and $\leq \mathcal{J}$ is a quasi-order. If $s \leq \mathcal{J} t$ and not $(s \mathcal{J} t)$, we write $s < \mathcal{J} t$. We say that a word $u$ is a factor of a word $v$ if $v = xuy$ for some $x, y \in X^*$. This is equivalent to saying that $v \leq \mathcal{J} u$ in the $\mathcal{J}$-order of $X^*$. Let $I_\equiv = (I_n)_n$ be the sequence of subsets of $X^*$ defined for each $n \geq 0$ by

$$I_n = \{w \in X^*||\{u\sigma|u \text{ is a factor of } w\}| \geq n\}.$$ 

**Theorem A.2.1:** Let $\equiv$ be an arbitrary congruence on $X^*$. Then $I_\equiv$ is a rational ideal filtration.

The proof of this theorem is actually an immediate consequence of the proof of Theorem 5.8 applied to $\sigma : X^* \rightarrow S$. We will indicate the structure of the proof of this theorem, as it is needed to prove Theorem A.2.1. Details can be found in [1, 6].

**Sketch of the proof of Theorem 5.8:** Let $\mathcal{P}_f(S^3)$ be the set of finite subsets of $S^3 = S \times S \times S$. For $(s_1, s_2, s_3)$ and $(s_4, s_5, s_6)$ in $S^3$ we define

$$\begin{align*}
(s_1, s_2, s_3) \ast (s_4, s_5, s_6) &= \left(\prod_{i=1}^{n_1} s_i, \prod_{i=n_1+1}^{n_2} s_i, \prod_{i=n_2+1}^{6} s_i\right) \\
&\quad \text{where } 0 \leq n_1 \leq n_2 \leq 6
\end{align*}$$

with empty products equal to 1 by convention. This operation is extended to $\mathcal{P}_f(S^3)$ by

$$A \ast B = \{a \ast b|a \in A, b \in B\}$$

for all $A, B \in \mathcal{P}_f(S^3)$, which makes $\mathcal{P}_f(S^3)$ a monoid. Moreover, letting

$$w\tau = \{(w_1\sigma, w_2\sigma, w_3\sigma)|w_1, w_2, w_3 \in X^*, w = w_1w_2w_3\}$$

for each $w \in X^*$ defines a morphism from $X^*$ into $\mathcal{P}_f(S^3)$. Let $\hat{S}^{(3)} = X^*\tau$. For each $(s_1, s_2, s_3)$ in $\mathcal{P}_f(S^3)$, let $(s_1, s_2, s_3)\pi = s_1s_2s_3$. Then $\sigma = \tau\pi$.

Next one verifies that if $w \in X^*$ and $w\sigma$ is an idempotent of $S$, then $w^5\tau = w^6\tau$. The argument is standard: if $w^6$ is factored as $w^6 = w_1w_2w_3$, 

Informatique théorique et Applications/Theoretical Informatics and Applications
then one of $w_1$, $w_2$ and $w_3$ contains $w^2$ as a factor. This shows that $\pi$ is bounded aperiodic.

For each $x \in \hat{S}^{(3)}$, let $\operatorname{set}(x)$ and $F(x)$ be the sets

\[
\operatorname{set}(x) = \{ s \in S | \exists s_1, s_2 \in S, (s_1, s, s_2) \in x \}
\]

and

\[
F(x) = \{ y \in \hat{S}^{(3)} | x \leq Jy \}.
\]

Then $\operatorname{set}(x)$ is a finite set, containing $x\pi$, and $x \leq Jy$ implies $\operatorname{set}(y) \subseteq \operatorname{set}(x)$. Therefore, for each fixed $x$, the set $\{ \operatorname{set}(y) | y \in F(x) \}$ is finite, and hence $F(x)$ is finite. By elementary facts of semigroup theory, if follows, that each strictly ascending chain in the $< J$-order is finite, each $J$-class of $\hat{S}^{(3)}$ is finite, and so is each of its subgroups.

For each $n \geq 1$ let us now define

\[
J_n = \{ x \in \hat{S}^{(3)} | |\operatorname{set}(x)| \geq n \}.
\]

Since $x \leq Jy$ implies $\operatorname{set}(y) \subseteq \operatorname{set}(x)$, $J_n$ is an ideal, and $\bigcap_n J_n = \emptyset$. We now want to prove that $\hat{S}^{(3)} \setminus J_n$ is finite for all $n$.

Since $J_0 = \hat{S}^{(3)}$, it will be sufficient to show that

\[
J_n \setminus J_{n+1} = \{ x \in \hat{S}^{(3)} | |\operatorname{set}(x)| = n \}
\]

is finite for all $n$. Note that $J_0$ is a finitely generated semigroup. We will prove by induction on $n$ that $J_n \setminus J_{n+1}$ is finite and $J_{n+1}$ is finitely generated (as a semigroup) for all $n \geq 0$. If $J_n$ is generated by a finite set $X_n \subseteq J_n$ and if $x = x_1 \ldots x_k$ ($x_i \in X_n$), then we have $\operatorname{set}(x_i) \subseteq \operatorname{set}(x)$ for all $i$. Thus $|\operatorname{set}(x)| = n$ implies $\operatorname{set}(x) = \operatorname{set}(x_i)$ for all $1 \leq i \leq k$. Therefore $J_n \setminus J_{n+1}$ is contained in the union of the sets $\operatorname{set}^{-1}(\operatorname{set}(x))$ when $x \in X_n$ and hence is finite. Let now

\[
Y_n = \{ rx | r \in J_n \setminus J_{n+1} \cup \{1\}, x \in X_n \text{ and } rx \in J_{n+1} \}
\]

and $X_{n+1} = Y_n \cup Y_n (J_n \setminus J_{n+1})$. Then $X_{n+1}$ is finite and, since $J_{n+1}$ is an ideal, $X_{n+1}$ is contained in $J_{n+1}$. Let now $y \in J_{n+1}$. Then $y = x_1 \ldots x_k$ for some $x_1, \ldots, x_k \in X_n$. Let $k_1 \geq 0$ be minimal such that
$x_1 \ldots x_{k_1 + 1} \in J_{n + 1}$. Then $r_1 = x_1 \ldots x_{k_1} \in J_n \backslash J_{n + 1}$ and $r_1 x_{k_1 + 1} \in Y_n$. Iterating this reasoning we obtain a factorization

$$y = x_1 \ldots x_k = (r_1 x_{k_1 + 1}) (r_2 x_{k_2 + 1}) \ldots (r_k x_{k_k + 1}) r_{k + 1}$$

with $r_1 x_{k_1 + 1} \in Y_n$, $\ldots$, $r_k x_{k_k + 1} \in Y_n$ and $r_{k + 1} \in J_n \backslash J_{n + 1} \cup \{1\}$. Thus $X_{n + 1}$ is a finite system of generators for $J_{n + 1}$. \hfill \Box

**Remark:** Using the notations of the above proof, let

$$K_n = \{ x \in \hat{S}^{(3)} | h_J(x) \geq n \}.$$ 

We could prove in a similar fashion that $(K_n)_n$ is another sequence of ideals of $\hat{S}^{(3)}$ satisfying condition (4) of Theorem 5.8.

**Proof of Theorem A.2.1:** We use the notations of the above proof. Let $\tau_n : X^* \rightarrow \hat{S}^{(3)} \backslash J_n$ be the composition of the morphism $\tau : X^* \rightarrow \hat{S}^{(3)}$ with the projection of $\hat{S}^{(3)}$ onto $\hat{S}^{(3)} / J_n$. For $w \in X^*$, note that

$$\text{set}(w\tau) = \{ u\sigma | u \text{ is a factor of } w \}.$$ 

Therefore $I_n = J_n \tau^{-1}$, so that $I_n$ is an ideal and $I_n$ is recognized by the morphism $\tau_n$. Since $\hat{S}^{(3)} / J_n$ is finite, $I_n$ is rational. \hfill \Box

**Appendix 3: Generalization of Eilenberg’s variety theorem**

In this section we give a generalization of Eilenberg’s variety (or stream) theorem (see [4, 16]) which encompasses the classes of (bounded) torsion and aperiodic languages. Recall that for us, a language is always a subset of some free monoid $X^*$ where the alphabet $X$ is finite. We say that a monoid $S$ is in **syntactic** if it is the syntactic monoid of some language. In particular $S$ is necessarily finitely generated. If $P$ is a subset of a monoid $S$, we say that $P$ is **disjunctive** if for all $s, t \in S$

$$\forall u, v \in S, \quad usv \in P \iff utv \in P \quad \iff \quad s = t.$$ 

(In other words, the syntactic congruence of $P$ in $S$ is trivial.) The following result is well-known.

**Lemma A.3.1:** Let $S$ be a finitely generated monoid. Then $S$ is syntactic if and only if $S$ contains a disjunctive subset.

This lemma allows the description of a large class of syntactic monoids.
PROPOSITION A.3.2: Let $S$ be a finitely generated semigroup. Let us assume that $S$ admits a sequence of ideals $(J_n)_n$ such that

$$S = J_0 \supseteq J_1 \supseteq \ldots \supseteq J_n \supseteq \ldots$$

$\bigcap J_n = \emptyset$, and, for all $n \geq 0$ and for all pairs of distinct elements of $S$, $s \neq t$, there exists $u, v \in S$ such that

$$usv \neq utv \text{ and } usv, utv \in J_n.$$

Then $S$ is a syntactic monoid.

Proof: For each $x \in S$, let $r(x) = \min \{n \geq 0 | x \not\in J_n\}$. Notice that $S$ is countable since it is finitely generated. Let

$$(s_0, t_0), (s_1, t_1), \ldots, (s_n, t_n), \ldots$$

be an enumeration of the pairs of distinct elements of $S$. We now construct by induction two sequences $(u_n)_n$ and $(v_n)_n$ of elements of $S$ such that, for each $n$,

$$u_n s_n v_n \neq u_n t_n v_n$$

and

$$\max \left\{ r(u_n s_n v_n), r(u_n t_n v_n) \right\} > \max \left\{ r(u_i s_i v_i), r(u_i t_i v_i) \right\} | 0 \leq i \leq n \}.$$

By hypothesis, there exist $u_0$ and $v_0$ such that $u_0 s_0 v_0 \neq u_0 t_0 v_0$. Let us now assume that $u_0, \ldots, u_m$ have been chosen which satisfy (*) for all $n \leq m$. Let $r_m = \max \{ r(u_i s_i v_i), r(u_i t_i v_i) | 0 \leq i \leq m \}$. By hypothesis, there exists $u_{m+1}$ and $v_{m+1}$ such that $u_{m+1} s_{m+1} v_{m+1} \neq u_m t_{m+1} v_{m+1}$ and $u_{m+1} t_{m+1} v_{m+1} \in J_r$, that is, $r(u_{m+1} s_{m+1} v_{m+1}) > r_m$ and $r(u_{m+1} t_{m+1} v_{m+1}) > r_m$. For these values of $u_{m+1}$ and $v_{m+1}$, (*) is again satisfied.

Let now $P = \{ u_n s_n v_n | n \geq 0 \}$. We claim that $P$ is a disjunctive subset of $S$, and hence that $S$ is syntactic by Lemma A.3.1. Indeed, if $s \neq t \in S$, then $s = s_n$ and $t = t_n$ for some $n$. Then $u_n s_n v_n = u_n s_n v_n \in P$. Furthermore, $u_n t_n v_n$ is not equal to $u_n s_n v_n$, and for all $i < n < j$, we have

$$r(u_i s_i v_i) < r(u_n t_n v_n) < r(u_j s_j v_j),$$

so that $u_n t_n v_n \not\in P$. \(\square\)
**Corollary A.3.3:** If $X$ is a finite alphabet, then $X^*$ is syntactic.

*Proof:* It is easy to verify that $X^*$ satisfies the hypothesis of Proposition A.3.2 for $J_n = \{w \in X^* | |w| \geq n\}$ $(n \geq 0)$. □

Let $V$ be a class of finitely generated monoids. We say that $V$ is a *variety of finitely generated monoids*, or *fg-variety*, if:

1. $V$ is not empty.
2. If $S_1, S_2 \in V$, then $S_1 \times S_2 \in V$.
3. If $S \in V$, if $T$ is finitely generated and if $T$ divides $S$, then $T \in V$,
4. For each $S \in V$, there exists a finite collection $S_1, \ldots, S_n$ of monoids in $V$ which are syntactic and such that $S < S_1 \times \ldots \times S_n$.

*Remark:* We could also define an *fg-variety* by properties (1)-(3), and then restrict ourselves to fg-varieties which are generated by a class of syntactic monoids.

*Example:* Let $FG$ be the class of all finitely generated monoids. Then $FG$ is an fg-variety. Indeed, by Corollary A.3.3., each finitely generated monoid is a quotient of a syntactic monoid. The usual varieties of finite monoids, or $M$-varieties are exactly the fg-varieties consisting only of finite monoids.

Let $L$ be a class of languages. We say that $L$ is a *variety of languages* if:

1. $L$ is not empty.
2. $L$ satisfies $(H^{-1})$.
3. $L$ satisfies $(BT)$.

*Example:* The class $L_{all}$ of all languages is a variety. The result of Section 4 show that, for $k \geq 1$, $L_{btor}^{(k)}$, $L_{bap}^{[k]}$, $L_{btor}$, $L_{bap}$, $L_{tor}$ and $L_{ap}$ are varieties of languages. Also, the usual varieties of rational languages are exactly the varieties of languages consisting only of rational languages.

Let $V$ be an fg-variety. We define $L(V)$ to be the class of all languages whose syntactic monoid is in $V$, or equivalently, the class of all languages that are recognized by some monoid in $V$. Also, it if $L$ is a class of languages, we let $V(L)$ be the fg-variety generated by the syntactic monoids of the languages of $L$. With these notations, we can state the following generalization of Eilenberg's variety theorem.

**Theorem A.3.4:** The correspondence $V \mapsto L(V)$ is one-to-one and onto from the class of all fg-varieties onto the class of all varieties of languages. Furthermore the reciprocal correspondence is given by $L \mapsto V(L)$.
Proof: The proof is very similar to that of Eilenberg's variety theorem. Let $V$ be an fg-variety. We verify that $\mathcal{L}(V)$ is a variety of languages by an immediate application of Lemma 1.2 and Proposition 1.3.

It is clear that, if $V$ and $W$ are fg-varieties and $V \subseteq W$, then $\mathcal{L}(V) \subseteq \mathcal{L}(W)$. Let us prove that the converse holds, that is, that $\mathcal{L}(V) \subseteq \mathcal{L}(W)$ implies $V \subseteq W$. Note that this will prove that the correspondence $V \mapsto \mathcal{L}(V)$ is one-to-one. Let $S \in V$. By definition of an fg-variety, we have $S < S_1 \times \ldots \times S_n$ where $S_i \in V$ and $S_i$ is the syntactic monoid of some language $L_i$. Then each $L_i$ is in $\mathcal{L}(V)$ and hence in $\mathcal{L}(W)$. Therefore $S_i \in W$ for each $i$ and hence $S \in W$.

Finally let $\mathcal{L}$ be a variety of languages. We will show that $\mathcal{L}(\mathcal{L}(\mathcal{L})) = \mathcal{L}$, thus showing that the correspondences $V \mapsto \mathcal{L}(V)$ and $\mathcal{L} \mapsto \mathcal{L}(\mathcal{L})$ are mutually reciprocal. The inclusion $\mathcal{L} \subseteq \mathcal{L}(\mathcal{L}(\mathcal{L}))$ is trivial. To prove the converse we consider $L \subseteq X^*$ with $L \in \mathcal{L}(\mathcal{L}(\mathcal{L}))$. We know that the syntactic monoid of $L$, $S = S(L)$, is in $\mathcal{V}(\mathcal{L})$ and hence that there exist finitely many languages $L_1 \subseteq X_1^*, \ldots, L_n \subseteq X_n^*$ such that $L_1, \ldots, L_n \in \mathcal{L}$ and $S$ divides $S_1 \times \ldots \times S_n$ (where $S_i$ is the syntactic monoid of $L_i$). Let $\eta_1, \ldots, \eta_n$ be the syntactic morphisms of $L_1, \ldots, L_n$ and let $e$ be a symbol not in $\bigcup_{i=1}^{n} X_i$. For each $1 \leq i \leq n$ we define a morphism $\sigma_i : (X_i \cup \{e\})^* \to X_i^*$ by $x \sigma_i = x$ for all $x \in X_i$ and $e \sigma_i = 1$. Let

$$Y = (X_1 \cup \{e\}) \times \ldots \times (X_n \cup \{e\}).$$

Then $\sigma = (\sigma_1, \ldots, \sigma_n)$ is a morphism from $Y^*$ onto $X_1^* \times \ldots \times X_n^*$. Finally let $\eta = (\eta_1, \ldots, \eta_n)$. Then $\eta$ is an onto morphisms from $\prod_{i=1}^{n} X_i^*$ onto $\prod_{i=1}^{n} S_i$.

Now $S$ divides $S_1 \times \ldots \times S_n$, so $L$ is recognized by $S_1 \times \ldots \times S_n$. That is, there exists a morphism $\varphi : X^* \to S_1 \times \ldots \times S_n$ and a subset $P$ such that $L = P \varphi^{-1}$. Since $\sigma \eta$ is onto there exists a morphism $\pi : X^* \to Y^*$ such that $\varphi = \pi (\sigma \eta)$. Therefore $L = P (\sigma \eta)^{-1} \pi^{-1}$ and it suffices to show that $P (\sigma \eta)^{-1} \in \mathcal{L}$. The situation is summarized by the following commutative diagram where $\pi_i$ and $\pi'_i$ are the $i$-th projections.

\[
\begin{array}{ccc}
Y^* & \xrightarrow{\sigma} & X_1^* \times \ldots \times X_n^* \\
\pi & \downarrow \eta & \pi_i \\
X^* & \xrightarrow{\sigma} & S_1 \times \ldots \times S_n \xrightarrow{\pi'_i} S_i
\end{array}
\]
In particular \( \pi_i \eta_i = \eta \pi_i' \) for all \( 1 \leq i \leq n \). Let \( P_i = L_i \eta_i \) and let

\[
L'_i = (S_1 \times \ldots \times S_{i-1} \times P_i \times S_{i+1} \times \ldots \times S_n) \eta_i^{-1} \sigma_i^{-1} \\
= (X'_i \times \ldots \times X'_{i-1} \times L_i \times X'_{i+1} \times \ldots \times X'_n) \sigma_i^{-1} \\
= L_i \pi_i^{-1} \sigma_i^{-1}.
\]

Note that \( L'_i = P_i (\sigma \eta \pi_i')^{-1} \) so that \( \sigma \eta \pi_i' \) recognizes \( L_i \). We show that \( \sigma \eta \pi_i' = \sigma \eta \pi_i \) is in fact the syntactic morphism of \( L_i \). Let \( u, v \in Y^* \) be syntactically equivalent (for \( L_i \)). Then for all \( x, y \in Y^* \), \( (xuy) \sigma \eta \pi_i' = (xuy) \sigma \pi_i \eta_i \in P_i \) if and only if \( (xuy) \sigma \pi_i = (xuy) \sigma \pi_i \eta_i \in P_i \). Therefore \( (xuy) \sigma \pi_i \in L_i \) if and only if \( (xuy) \sigma \pi_i \in L_i \), that is, \( u \sigma \pi_i \eta_i = v \sigma \pi_i \eta_i \) and hence \( u \sigma \eta \pi_i' = v \sigma \pi_i \eta_i \).

By Proposition 1.3, \( P (\sigma \eta)^{-1} \in B (L'_1, \ldots, L'_n) \). But \( L'_i = L_i \pi_i^{-1} \), so \( L_i' \in \mathcal{L} \) and hence \( P (\sigma \eta)^{-1} \in \mathcal{L} \). \( \Box \)

**Example:** We already remarked that the correspondences between M-varieties and varieties of rational languages (see Pin [16]) are instances of the correspondence described in Theorem A.3.4. Other examples are given in the following thereom.

**Theorem A.3.5.** — Let \( k \) be an integer with \( k \geq 6 \). The classes \( \mathbf{F} \mathbf{G} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{bT} \mathbf{O} \mathbf{r} \mathbf{k} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{bA} \mathbf{P} \mathbf{k} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{bT} \mathbf{o} \mathbf{r} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{bA} \mathbf{P} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{T} \mathbf{o} \mathbf{r} \) and \( \mathbf{F} \mathbf{G} \cap \mathbf{A} \mathbf{p} \) are \( \mathbf{f} \mathbf{g} \)-varieties. We have the following correspondences:

\[
\begin{align*}
\mathbf{bT} \mathbf{o} \mathbf{r} \mathbf{k} & \mapsto \mathcal{L}^{(k)}_{\mathbf{bT} \mathbf{o} \mathbf{r}} & \mathbf{bA} \mathbf{P} \mathbf{k} & \mapsto \mathcal{L}^{[k]}_{\mathbf{bA} \mathbf{P}} \\
\mathbf{bT} \mathbf{o} \mathbf{r} & \mapsto \mathcal{L}^{(k)}_{\mathbf{bT} \mathbf{o} \mathbf{r}} & \mathbf{bA} & \mapsto \mathcal{L}^{[k]}_{\mathbf{bA} \mathbf{P}} & \mathbf{F} \mathbf{G} & \mapsto \mathcal{L}^{(k)}_{\mathbf{F} \mathbf{G}} \\
\mathbf{T} \mathbf{o} \mathbf{r} & \mapsto \mathcal{L}^{(k)}_{\mathbf{T} \mathbf{o} \mathbf{r}} & \mathbf{A} \mathbf{p} & \mapsto \mathcal{L}^{[k]}_{\mathbf{A} \mathbf{p}}
\end{align*}
\]

**Proof:** After the results of Section 4, the only part of the statement that remains to be established is that \( \mathbf{F} \mathbf{G} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{bT} \mathbf{o} \mathbf{r} \mathbf{k} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{bA} \mathbf{P} \mathbf{k} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{bT} \mathbf{o} \mathbf{r} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{bA} \mathbf{P} \), \( \mathbf{F} \mathbf{G} \cap \mathbf{T} \mathbf{o} \mathbf{r} \) and \( \mathbf{F} \mathbf{G} \cap \mathbf{A} \mathbf{p} \) are \( \mathbf{f} \mathbf{g} \)-varieties, that is, that these classes are generated by their syntactic members. This was noted earlier for \( \mathbf{F} \mathbf{G} \).

Each monoid in \( \mathbf{F} \mathbf{G} \cap \mathbf{bT} \mathbf{o} \mathbf{r} \mathbf{k} \) (resp. \( \mathbf{F} \mathbf{G} \cap \mathbf{bA} \mathbf{P} \mathbf{k} \)) divides a monoid of the form \( B_X (k, k) \) (resp. \( B_X (k, 1) \)) for some finite alphabet \( X \). Note that \( B_X (k, k) \in \mathbf{F} \mathbf{G} \cap \mathbf{bT} \mathbf{o} \mathbf{r} \mathbf{k} \) and \( B_X (k, 1) \in \mathbf{F} \mathbf{G} \cap \mathbf{bA} \mathbf{P} \mathbf{k} \). In fact, each monoid in \( \mathbf{F} \mathbf{G} \cap \mathbf{T} \mathbf{o} \mathbf{r} \) (resp. \( \mathbf{F} \mathbf{G} \cap \mathbf{A} \mathbf{p} \)) divides a monoid of the form \( B_X (k, k) \) (resp. \( B_X (k, 1) \)) for some finite alphabet \( X \) and some integer \( k \geq 6 \). So it suffices to show that, for \( k \geq 6, l \geq 1 \) and \( X \) finite, the monoid \( B_X (k, l) \) is syntactic.
We will not prove this fact. Let us just say that readers familiar with McCammond [11] can use the notion of rank to prove that $B_X (k, l)$ satisfies the hypothesis of Proposition A.3.2., and hence is syntactic.

Similar, in order to prove that $\mathbf{FG} \cap \mathbf{Tor}$ and $\mathbf{FG} \cap \mathbf{AP}$ are fg-varieties, it suffices to show that, for all $S \in \mathbf{FG} \cap b\mathbf{Tor}$ (resp. $S \in \mathbf{FG} \cap \mathbf{AP}$), then $\bar{S}$ is syntactic. Note that $\bar{S} \in \mathbf{FG} \cap b\mathbf{Tor}$ (resp. $\mathbf{FG} \cap b\mathbf{AP}$) since the morphism $\psi$ of Theorem 5.9 is aperiodic. Again, we leave it to readers familiar with Rhodes [17] to prove that $\bar{S}$ satisfies the hypothesis of Proposition A.3.2. This can be done using the natural filtration given by the length of the infinite iteration matrix semigroup (IIMS) description of $\bar{S}$. □
