ITERATIVE REFINEMENT OF FINITE ELEMENT APPROXIMATIONS FOR ELLIPTIC PROBLEMS (*)

by Lin QUN ⁽¹⁾

Communiqué par J A NITSCHÉ

Résumé — On présente une extrapolation itérative d'approximations de problèmes elliptiques par des éléments fins de bas degré

Abstract — An iterative refinement of low-degree finite element approximations for elliptic problems is presented

1. We will consider the boundary value problem

$$\Delta u + \sum a_i \frac{\partial u}{\partial x_i} + bu = -f \quad \text{in } \Omega,$$
$$u = 0 \quad \text{on } \partial\Omega. \quad (1)$$

Here $\Omega \subset \mathbb{R}^N$ is a bounded domain with boundary $\partial\Omega$ sufficiently smooth. We will adopt the standard notations (cf. Gilbarg-Trudinger, 1977). Especially $(., .)$ respective $(., .)_1$ denote the $L_2(\Omega)$ -inner-product respective the Dirichlet integral and $\| . \|_k$ the norm in $H_k = W_2^k(\Omega)$.

The weak formulation of problem (1) is $u \in \overset{\circ}{H}_1$ and

$$(u, v)_1 = (\sum a_i u |_{,i} + bu + f, v) \quad \text{for } v \in \overset{\circ}{H}_1. \quad (2)$$

Our basic assumption is : problem (1) resp. (2) has a unique solution u to $f \in H_0$ with $u \in \overset{\circ}{H}_1 \cap H_2$ and $\| u \|_2 \leq c \| f \|$. Now let S_h be the space of linear finite

(*) Reçu le 17 mars 1981.

(1) Institute of Mathematics, Academia Sinica, Beijing, Chine

elements with isoparametric modifications in the boundary elements such that $S_h \subset \mathring{H}_1$ holds true. Due to an argument of Schatz (1974) for h sufficiently small the Galerkin-approximation $u^0 = u_h \in S_h$ defined by

$$(u^0, \chi)_1 = \left(\sum a_i u^0 |_{\cdot} + bu^0 + f, \chi \right) \quad \text{for } \chi \in S_h \quad (3)$$

is uniquely defined. The error estimate

$$\|u - u^0\| + h \|u - u^0\|_1 \leq ch^2 \|u\|_2 \quad (4)$$

is well known.

In Lin Qun (1978), (1980) we introduced a refinement of u^0 on the basis of the additional assumption: to $F \in H_0$ given the solution of

$$\begin{aligned} -\Delta U &= F & \text{in } \Omega, \\ U &= 0 & \text{on } \partial\Omega \end{aligned} \quad (5)$$

resp. $U \in \mathring{H}_1$ and

$$(U, v)_1 = (F, v) \quad \text{for } v \in \mathring{H}_1 \quad (6)$$

is computable. Then given u^0 we can compute \bar{u}^0 defined by $\bar{u}^0 \in \mathring{H}_1$ and

$$(\bar{u}^0, v)_1 = \left(\sum a_i u^0 |_{\cdot} + bu^0 + f, v \right) \quad \text{for } v \in \mathring{H}_1. \quad (7)$$

This leads to a higher accuracy in the H_1 -norm:

$$\|u - \bar{u}^0\|_1 \leq ch^2 \|u\|_2. \quad (8)$$

Of course \bar{u}^0 is not an element of S_h .

Following a suggestion of Nitsche (private communication) we construct starting with the pair (u^0, \bar{u}^0) iterates (u^{v+1}, \bar{u}^{v+1}) for $v \geq 0$ defined

$$u^{v+1} = \bar{u}^v + \varphi^v \quad (9)$$

with $\varphi^v \in S_h$ and

$$\begin{aligned} (\varphi^v, \chi)_1 - \left(\sum a_i \varphi^v |_{\cdot} + b\varphi^v, \chi \right) &= \\ &= \left(\sum a_i (\bar{u}^v - u^v) |_{\cdot} + b(\bar{u}^v - u^v), \chi \right) \quad \text{for } \chi \in S_h \end{aligned} \quad (10)$$

and on the other hand by $(v \geq 0)$

$$(\bar{u}^v, v)_1 = \left(\sum a_i u^v |_{\cdot} + bu^v + f, v \right) \quad \text{for } v \in \mathring{H}_1. \quad (11)$$

In Section 3 we give the proof of :

THEOREM 1 : *Let (u^v, \bar{u}^v) be defined as above. Then*

$$\| u - u^v \| + \| u - \bar{u}^v \|_1 \leq (ch)^{v+2} \| u \|_2$$

is valid.

2. Our proof is based on the following operator frame work (cf. Chatelin, 1981, Hackbusch, 1981). Let us consider the equation

$$u = Ku + y \tag{12}$$

in a Banach-space X with K being a linear compact operator. Further let S be an approximating subspace and $P : X \rightarrow S$ a bounded projection onto S . The standard Galerkin solution is defined by

$$u^0 = PKu^0 + Py. \tag{13}$$

Now we construct iterates \bar{u}^v and u^{v+1} in the way

$$\bar{u}^v = Ku^v + y, \tag{14}$$

$$u^{v+1} = \bar{u}^v + r^v \tag{15}$$

with r^v defined by

$$r^v = PKr^v + PK(\bar{u}^v - u^v). \tag{16}$$

Remark 1 : $d^v = \bar{u}^v - u^v = Ku^v - u^v + y$ is the defect of the v -th iterate. Therefore r^v may be interpreted as the Galerkin-solution to the right hand side Kd^v .

Remark 2 : The approximations \bar{u}^0 are also considered in Sloan (1976), but the higher iterates introduced there differ from ours.

LEMMA 1 : *Suppose that K is compact, 1 is not an eigenvalue of K and $\kappa : = \| (I - P) K \|$ is sufficiently small.*

Then $(I - PK)^{-1}$ exists as a bounded operator in X and the Galerkin solutions are well defined. Moreover

$$u - u^v = (I - PK)^{-1} (I - P) K(u - u^{v-1}). \tag{17}$$

Proof : Since $(I - K)^{-1}$ is bounded for κ small enough also $(I - PK)^{-1}$ is bounded. As a consequence the Galerkin solution is uniquely defined. The identity

$$(I - K)^{-1} = (I - PK)^{-1} + (I - PK)^{-1} (I - P) K(I - K)^{-1} \tag{18}$$

will be useful. The solution u of (12) may be written in the form

$$u = (I - PK)^{-1} y + (I - PK)^{-1} (I - P) Ku. \quad (19)$$

Because of our construction we have

$$\begin{aligned} u^{v+1} &= Ku^v + y + (I - PK)^{-1} PK(Ku^v + y - u^v) \\ &= (I - PK)^{-1} y + (I - PK)^{-1} (I - P) Ku^v. \end{aligned} \quad (20)$$

Subtraction of (20) from (19) gives (17).

Remark 3 : We mention that under our assumptions also $(I - KP)^{-1}$ exists and the recurrence relation

$$u - \bar{u}^v = (I - KP)^{-1} K(I - P)(u - \bar{u}^{v-1}) \quad (21)$$

is valid. The proof is omitted.

By our assumptions $\|u^0\|$ is bounded by a multiple of $\|y\|$. Because of

$$\|(I - PK)^{-1}\| \leq \frac{\gamma}{1 - \kappa\gamma} \quad (22)$$

with γ being the norm of $\|(I - K)^{-1}\|$ we conclude from lemma 1 :

COROLLARY 1 : Let $\kappa = \|(I - P)K\|$ be less than the half of

$$\gamma^{-1} = \|(I - K)^{-1}\|^{-1}.$$

Then error-estimates of the type

$$\|u - u^v\| \leq c \left\{ \frac{\kappa\gamma}{1 - \kappa\gamma} \right\}^v \|y\| \quad (23)$$

hold true.

3. Now we come back to the situation discussed in section 1. We identify X with the Hilbertspace $H_0 = L_2(\Omega)$. Since we want to work with the Ritz-method we have to impose the condition $S \subseteq \overset{\circ}{H}_1$. For simplicity we focuss our attention to the case : $S = S_h$ is the space of linear finite elements with isoparametric modifications along the boundary. Further let $P = R_h$ be the standard Ritz-projection defined by $Pu \in S_h$ and

$$(Pu, \chi)_1 = (u, \chi)_1 \quad \text{for } \chi \in S_h. \quad (24)$$

The operator K is defined by

$$w = Kv \Leftrightarrow w \in \mathring{H}_1 \quad \text{and} \quad (w, g)_1 = (v, -\sum (a_i g)|_i + bg) \quad \text{for} \quad g \in \mathring{H}_1. \quad (25)$$

Under suitable conditions concerning the regularity of a_i, b and since the original problem (1) resp. (2) is assumed to be uniquely solvable K is a bounded operator from H_0 into \mathring{H}_1 and hence compact as mapping of H_0 into itself.

By duality the error-estimate

$$\|u - Pu\| \leq ch \|u\|_1 \quad (26)$$

is a consequence of (4). Because of

$$\|(I - P)Kv\| \leq ch \|Kv\|_1 \leq c' h \|v\| \quad (27)$$

we find

$$\kappa = \kappa_h = \|(I - P)K\| \leq ch \quad (28)$$

with some constant c .

The estimates derived in section 2 lead to

$$\|u - u^v\| \leq (ch)^v \|u - u^0\| \quad (29)$$

and because of (4) to

$$\|u - u^v\| \leq (ch)^{v+2} \|u\|_2. \quad (30)$$

Finally the terms $\|u - \bar{u}^v\|_1$ are bounded in the same way since by definition

$$u - \bar{u}^v = K(u - u^v). \quad (31)$$

This completes the proof of theorem 1.

4. In this section we consider the model problem

$$\begin{aligned} -\Delta u &= f(\cdot, u) && \text{in } \Omega \\ u &= 0 && \text{on } \partial\Omega \end{aligned} \quad (32)$$

in two or three space dimensions. The weak formulation of (32) is : Find $u \in \mathring{H}_1$ such that

$$(u, v)_1 = (f(u), v) \quad \text{for} \quad v \in \mathring{H}_1. \quad (33)$$

Our assumptions are :

(i) $f(x, z)$ is twice continuously differentiable with respect to $z \in \mathbb{R}$ and

$$|f_{zz}(x, z)| \quad (34)$$

is uniformly bounded.

(ii) For $z = u(x) \in C^0(\bar{\Omega})$ the functions $f(x, u(x))$, $f_x(x, u(x))$ and $f_{zz}(x, u(x))$ are in $C^0(\bar{\Omega})$.

(iii) u is an isolated solution of (32), i.e. the linear problem

$$(w, g)_1 = (f'(u) w, g) \quad \text{for } g \in \mathring{H}_1 \quad (35)$$

admits only $w = 0$ in \mathring{H}_1 .

Now let $u^0 = u_h \in S_h$ be the solution of the corresponding Galerkin-problem

$$(u^0, \chi)_1 = (f(u^0), \chi) \quad \text{for } \chi \in S_h. \quad (36)$$

Corresponding to section 1 we define the iterates \bar{u}^v for $v \geq 0$ by

$$(\bar{u}^v, g)_1 = (f(u^v), g) \quad \text{for } g \in \mathring{H}_1, \quad (37)$$

and

$$u^{v+1} = \bar{u}^v + \varphi^v \quad (38)$$

with $\varphi^v \in S_h$ and

$$(\varphi^v, \chi)_1 = (f'(u^0)(\varphi^v + \bar{u}^v - u^v), \chi) \quad \text{for } \chi \in S_h. \quad (39)$$

The counterpart of theorem 1 is :

THEOREM 2 : *Let (u^v, \bar{u}^v) be defined as above. Then*

$$\|u - u^v\| + \|u - \bar{u}^v\|_2 \leq c_1(c_2 h^2)^{v+1} \quad (40)$$

is valid. The constants c_1, c_2 depend on u and bounds of f_x, f_{zz} but are independent of h and v .

Proof : Let $K : H_0 \rightarrow \mathring{H}_1 \cap H_2$ be the inverse of the Laplacian defined by

$$w = Kv \Leftrightarrow (w, g)_1 = (v, g) \quad \text{for } g \in \mathring{H}_1, \quad (41)$$

and let $P = R_h$ be the Ritz operator defined by

$$\Phi = Pv \Leftrightarrow \Phi \in S_h \quad \text{and} \quad (\Phi, \chi)_1 = (v, \chi)_1 \quad \text{for } \chi \in S_h. \quad (42)$$

Problem (32) is equivalent to $u = Kf(u)$. We may rewrite this in the form

$$(I - PKf'(u^0)) u = Kf(u) - PKf'(u^0) u. \quad (43)$$

In terms of K and P the iterates \bar{u}^v and φ^v have the representation

$$\bar{u}^v = Kf(u^v), \quad (44)$$

$$(I - PKf'(u^0)) \varphi^v = PKf'(u^0) (\bar{u}^v - u^v). \quad (45)$$

This leads to

$$(I - PKf'(u^0)) u^{v+1} = Kf(u^v) - PKf'(u^0) u^v. \quad (46)$$

By comparison of (43) and (46) and by adding and subtracting appropriate terms we come to

$$(I - PKf'(u^0)) (u^{v+1} - u) = (I - P) Kf'(u^0) (u^v - u) + K \{ f(u^v) - f(u) - f'(u) (u^v - u) + f'(u) - f'(u^0) \} (u^v - u). \quad (47)$$

The Ritz operator P is the orthogonal projection in H_1 onto $S = S_h$. For $v, w \in H_0$ arbitrary we get

$$\begin{aligned} ((I - P) Kv, w) &= ((I - P) Kv, Kw)_1 \\ &= ((I - P) Kv, (I - P) Kw)_1 \\ &\leq ch^2 \|Kv\|_2 \|Kw\|_2 \leq ch^2 \|v\| \|w\|. \end{aligned} \quad (48)$$

This implies that the norm of $(I - P)K$ as mapping of H_0 into H_0 is bounded by ch^2 . Next let a be a continuous function and $v, w \in H_0$. Then also $K(avw)$ is in H_0 and

$$\|K(avw)\| \leq c \|v\| \|w\|. \quad (49)$$

This follows from

$$\|K(avw)\|_0 = \sup \{ (Kavw, g) \mid \|g\| = 1 \} \quad (50)$$

and

$$(K(avw), g) = (v, \{ aKg \} w) \quad (51)$$

in combination with Sobolev's embedding lemma.

For h small enough the initial Galerkin solution u^0 is "near" to u . Because of our assumption (iii) then the operator $I - PKf'(u^0)$ will have a bounded inverse.

By the aid of these arguments we derive from the recurrence relation (47) the corresponding error bound

$$\|u^{v+1} - u\| \leq c_3 h^2 \|u^v - u\| + c_4 \|u^v - u\|^2 + c_5 \|u^0 - u\| \|u^v - u\|. \quad (52)$$

For the sake of clarity we have numbered the constants. Since an estimate of the type

$$\|u^0 - u\| \leq ch^2 \quad (53)$$

holds true anyway we derive from (52)

$$\|u^{v+1} - u\| \leq c_6 h^2 \|u^v - u\| + c_4 \|u^v - u\|^2. \quad (54)$$

Because of (53) by complete inductions there is a constant c_7 such that for $h \leq h_0$ with h_0 chosen appropriate the relation

$$\|u^{v+1} - u\| \leq c_7 h^2 \|u^v - u\| \quad (55)$$

holds true (55) together with (53) lead to the error bound stated in theorem 2 for $u^v - u$.

Because of

$$\bar{u}^v - u = K(f(u^v) - f(u)) \quad (56)$$

we come to

$$\begin{aligned} \|\bar{u}^v - u\|_2 &\leq c \|f(u^v) - f(u)\| \\ &\leq c \|u^v - u\|. \end{aligned} \quad (57)$$

Remark 3 : Whereas assumption (iii) is essential the two preceding ones can be reduced.

ACKNOWLEDGEMENT

I want to thank W. Hackbusch, J Liu and J. Nitsche for their suggestions and discussions
