THE $p$ VERSION OF MIXED FINITE ELEMENT METHODS FOR PARABOLIC PROBLEMS (*) (1)

by Sonia M. F. Garcia (2) and Søren Jensen (3)

Abstract — We investigate a parabolic problem from the point of view of stability and approximation properties of increasing order mixed (in space) finite element methods. Previous estimates for the Raviart Thomas projection are proven to be sharp. We analyze the effects of mixed finite element discretization in space to present transient error estimates (for semidiscrete mixed finite element methods). The results in this paper (submitted in Oct 1993) complement the results already published in [6 8]

Résumé — Un problème parabolique a été étudié d’un point de vue stabilité, ainsi que des propriétés d’approximation des méthodes des éléments finis mixtes (en espace) d’ordre croissant. Il est montré que des estimations précédentes faites sur la projection Raviart-Thomas sont précises. Nous avons pu analyser les effets de la discretisation du méthode des éléments finis, en espace, afin de présenter des estimations d’erreurs transitoires (pour des méthodes des éléments finis mixtes semidiscrets). Les résultats de cet article (soumis en Oct 1993) complètent les résultats déjà publiés dans les references [6 8]

1. INTRODUCTION

Consider the following parabolic initial, boundary value problem

$$c(x, t) u_t - \nabla \cdot (a(x, t) \nabla u(x, t) + b(x, t)) = f(x, t), \quad (x, t) \in \Omega \times J,$$

$$u(x, 0) = u_0(x), \quad x \in \Omega,$$

$$u(x, t) = g(x, t), \quad (x, t) \in \partial \Omega \times J$$

Mathematical Modelling and Numerical Analysis © AFCET Gauthier Villars
Here, $\Omega$ is a convex, plane polygonal domain, $J = (0, T)$, and we assume that $a, b_1, b_2, c \in C^\infty(\bar{\Omega} \times J)$ and that $\inf_{x \in \Omega, t \in J} a(x, t) > 0$ as well as $\inf_{x \in \Omega, t \in J} c(x, t) > 0$. We assume that this problem is well-posed and in particular that a solution exists at each time $t$ for

$$(f(\cdot, t), u_0(\cdot), g(\cdot, t)) \in L^2(\Omega) \times H^2(\Omega) \times H^{3/2}(\partial \Omega)$$

with the regularity estimate

$$\|u(\cdot, t)\|_2 \leq C(\|f(\cdot, t)\|_0 + |g(\cdot, t)|_{3/2})$$

where we have denoted the norms in the Sobolev spaces $H^m(\Omega)$ by $\|\cdot\|_m$ and in $H^s(\partial \Omega)$ by $|\cdot|_s$, respectively. We denote the ess sup norm in the space $L^\infty(\Omega)$ by $\|\cdot\|_\infty$.

Let $\sigma$ be a new variable denoting a « flux »:

$$\sigma := - (a(x, t) \nabla u(x, t) + b(x, t) u(x, t))$$

and define the spaces

$$V(\Omega) := L^2(\Omega), \text{ and,}$$

$$H(\text{div, } \Omega) \overset{\text{def}}{=} ([C^\infty(\Omega)]^2)\text{ closure under } \|\cdot\|_{H(\text{div})},$$

where we take the closure with respect to the norm defined by

$$\|\chi\|_{H(\text{div})}^2 \overset{\text{def}}{=} \|\chi\|_{L^2}^2 + \|\nabla \cdot \chi\|_{L^2}^2.$$

When it is clear from the context we will use $V$ and $H$ to denote $V(\Omega)$ and $H(\text{div, } \Omega)$.

A solution pair $(u, \sigma)(\cdot, t) \in V \times H$ of (1.1) may be thought of as a solution of the variational problem

$$(\sigma(x, t), \chi) + (a(x, t) \nabla u(x, t), \chi) + (b(x, t) u(x, t), \chi) = 0, \quad \forall \chi \in H,$$

$$(c(x, t) u_t(x, t), v) + (\text{div } \sigma(x, t), v) = (f(x, t), v),$$

$$\forall v \in V,$$

$$u(x, 0) = u_0(x), \quad (1.2)$$

where $(\cdot, \cdot, \cdot)$ is the usual $L^2(\Omega)$-inner product, and $u$ furthermore is subject to the boundary conditions in (1.1). The second term in the first equation of (1.2) is meant in the dual sense (using that $\chi \in H$).
Let
\[ \frac{1}{a(x, t)} = \alpha(x, t) \quad \text{and} \quad \frac{b(x, t)}{a(x, t)} = \beta(x, t). \]

Simplifying the notation by dropping \((x, t)\) for the time-dependent variables as well as dropping the \((x)\) for \(u_0\), (1.2) can be written as

\[ (\alpha \sigma, \chi) - (u, \text{div} \chi) + (\beta u, \chi) = \langle g, \chi \cdot v \rangle, \quad \forall \chi \in H, \tag{1.3} \]
\[ (cu, v) + (\text{div} \sigma, v) = (f, v), \quad \forall v \in V, \tag{1.4} \]
\[ u(\cdot, 0) = u_0, \tag{1.5} \]

where \(\langle \cdot, \cdot \rangle\) is the \(L^2\)-inner product on the boundary of \(\Omega\), i.e.,

\[ \langle w, v \rangle = \int_{\partial \Omega} w v \, ds \]

and \(v\) is the unit outward normal vector to \(\partial \Omega\).

This paper studies the behavior of a finite element method to be defined precisely in (1.6)-(1.8) using a fixed mesh as in [11]. As there we then pay particular attention to what happens as the polynomial degree of the finite elements is increased. This type of method is at times called a \(p\) version of the mixed finite element method, but could also be considered as a mixed, Galerkin spectral element method.

[6] has portrayed the \(h\)-version of the mixed finite element method for the quasilinear parabolic problem including the questions of uniqueness, existence, and convergence of the discrete solution as \(h \downarrow 0\).

Now, let us define some discrete subspaces, denoting by \(N\) some measure of the dimension of these. Let \(\mathcal{T}_N\) be a geometric partition of \(\Omega\) into parallelograms which we term geometric « elements » \(E\). Let \(Q^{p,q}\) be the set of polynomials in two variables \((x\) and \(y)\) of separate degree at most \(p\) (in \(x)\) and \(q\) (in \(y)\), respectively. If \(p = q\), we simply write \(Q^p\). For each \(E \in \mathcal{T}_N\), let \(F_E\) be an affine, orientation preserving (i.e., \((\det (DF_E)) > 0\)) mapping which maps \(E\) onto \(R = (-1, 1)^2\), a reference square. We then define two spaces of piecewise polynomials:

\[ V_N = \{ v \in L^2(\Omega) ; v|_E \circ F_E^{-1} \in Q^p, \forall E \in \mathcal{T}_N \} \]
\[ H_N = \{ \chi \in H(\text{div}) ; \chi|_E \circ F_E^{-1} \in Q^{p+1,p} \times Q^{p+1,p}, \forall E \in \mathcal{T}_N \} \]

Note that
\[ \text{div} H_N = V_N. \]
With the definitions already in place, also please note that a necessary and sufficient condition for the inclusion $H_N \subseteq H$ is that normal components (after convening on one common normal) are continuous across inter-element boundaries (whose common length is positive).

With the above definitions a discrete analogue to (1.2) is given by the following.

Find $(u_N, \sigma_N) \in V_N \times H_N$ such that

\[
\begin{align*}
(\alpha \sigma_N, \chi) - (u_N, \text{div} \chi) + (\beta u_N, \chi) &= (g, \chi \cdot v), \quad \forall \chi \in H_N \quad (1.6) \\
(c u_N, v) + (\text{div} \sigma_N, v) &= (f, v), \quad \forall v \in V_N, \quad (1.7) \\
u_N(0) &= U(0), \quad (1.8)
\end{align*}
\]

where $U(0)$ is the first component of an elliptic mixed method projection of $(u, \sigma)(0)$ onto the finite dimensional space $V_N \times H_N$ to be defined precisely in (2.4)-(2.5). Assume until then that $U(0)$ is well-defined. If one were to introduce bases for $H_N$ and $V_N$, one could rewrite (1.7) and (1.6) in matrix form:

\[
C(\hat{u}_N) - D(\hat{\sigma}_N) = F,
\]

\[
A(\hat{\sigma}_N) + D^T(\hat{u}_N) + B(\hat{u}_N) = G,
\]

with the initial value $(\hat{u}_N)(0)$ prescribed. The matrices $A$ and $C$ are symmetric and positive definite so that we may solve for $(\hat{\sigma}_N)$ in the second equation (uniquely in terms of $(\hat{u}_N)$). Now we interpret the first equation as a system of first order ordinary differential equations with a positive definite coefficient matrix of $(\hat{u}_N)$, which in turn determines $(\hat{u}_N)$ uniquely. Thus $(u_N, \sigma_N)$ exists and is uniquely defined.

2. ESTIMATES AT FIXED TIME FOR ELLIPTIC MIXED AND OTHER USEFUL PROJECTIONS

The main tools for our work are an elliptic-mixed projection, the Raviart-Thomas projection for the $p$-version for the mixed method, and also the $L^2$-projection onto polynomial subspaces to be defined below.

The $L^2$-projection onto $V_N$, $P_N : L^2 \to V_N$, is uniquely given by

\[
(P_N v - v, w) = 0, \quad w \in V_N,
\]
where by [12], e.g. we have the following estimates,

$$\| P_N u - v \|_0 \leq C p^{-m} \| u \|_m, \quad m \geq 0,$$

(2.1)

for $v \in H^m(\Omega)$.

As in [16], [11] and of course [13] we will use the Raviart-Thomas projection of $H$ onto $H_N$, $\Pi_N : H \to H_N$.

The definition of $\Pi_N$ is, for any $\chi \in H$:

$$\langle (\Pi_N \chi - \chi) \cdot v_E, v \rangle_{\partial E_i} = 0, \quad 1 \leq i \leq 4, \quad \forall v : v \circ F_E^{-1} \in Q^p,$$

$$\langle \Pi_N \chi - \chi, \rho \rangle_E = 0, \quad \forall \rho : \rho \circ F_E^{-1} \in Q^{p-1,p} \times Q^{p,p-1}.$$  (2.2)

$\Pi_N \chi$ exists and is unique by [13]. A consequence is the commutation property $\text{div} \, \Pi_N = P_N \text{div}$, or precisely,

$$\langle \text{div} \, \Pi_N \chi, v \rangle = \langle \text{div} \, \chi, v \rangle, \quad \forall v \in V_N, \forall \chi \in H.$$  

The approximation properties of $\Pi_N$ — as dependent on the parameter $p$ — were given in [11] extending results in [16]:

**Proposition 2.1** [[11] Prop. 2.1]: Let $\chi \in H$ and let $\Pi_N \chi$ be its Raviart-Thomas projection onto $H_N$ given by (2.2). Then, if $\chi \in (H'(\Omega))^2$, we have

$$\| \Pi_N \chi - \chi \|_0 \leq C p^{1/2-r} \| \chi \|_r, \quad r > 1/2,$$

(2.3)

where $C > 0$ is a constant independent of $p$ and $\chi$ but depending on $r$. Moreover, this estimate is sharp.

The inequality was proved in [16] for $r > 1$ and in [11] for $r > 1/2$. Concerning the sharpness of the inequality, the proof will depend on properties of the Legendre polynomials to be introduced in section 4. We will postpone the proof to Lemma 4.8 for that reason.

Define an elliptic-mixed-method projection $(U, \Sigma)$ of the solution pair $(u, \sigma)$ of the variational problem onto the finite dimensional space $V_N \times H_N$ to be the mapping $(U, \Sigma) : V \times H \times \mathbf{J} \to V_N \times H_N$ given by

$$(\alpha(\sigma - \Sigma), \chi) - (u - U, \text{div} \, \chi) + (\beta(u - U), \chi) = 0, \quad \forall \chi \in H_N,$$

(2.4)

$$(\text{div} \, (\sigma - \Sigma), v) + \lambda(u - U, v) = 0, \quad \forall v \in V_N,$$  (2.5)

where $\lambda$ is chosen to be independent of $t \in \mathbf{J}$ such that

$$(\alpha \phi, \phi) + (\beta \phi, \phi) + \lambda(\phi, \phi) \geq c^* (\| \phi \|_0^2 + \| \phi \|_0^2).$$
LEMMA 2.2: There exists a unique solution pair \((U, \Sigma)\) of (2.4)-(2.5). For any given \(\rho, \sigma\), the mapping

\[(u, \sigma)(\cdot, t) \in V \times H \rightarrow (U, \Sigma) \in V_N \times H_N\]

is a projection.

Proof: Since the linear system (2.4)-(2.5) is square, we need only verify uniqueness in order to also have existence. Suppose there exists another pair \((U', \Sigma')\) solving (2.4)-(2.5). Then take \(\chi = \Sigma - \Sigma'\) in (2.4) and \(v = U - U'\) in (2.5) and add the resulting equations to get:

\[
\alpha(\Sigma - \Sigma') + (\beta(U - U'), \Sigma - \Sigma') + \lambda(U - U', U - U') = 0,
\]

where then the coercivity above yields uniqueness. This also proves the mapping defined in (2.4)-(2.5) is a projection. \(\square\)

Let us ease the notation by setting,

\[
\xi = U - u_N, \quad \text{and} \quad \zeta = \Sigma - \sigma_N,
\]

so that \(\| (\xi, \zeta) \|\) is the distance from the elliptic projection to the finite element solution, and

\[
\eta = u - U, \quad \text{and} \quad \rho = \sigma - \Sigma,
\]

so that \(\| (\eta, \rho) \|\) is the distance from the elliptic projection to the exact solution.

In order to estimate these distances and the corresponding distances of \((\rho, \rho_t)\) — their partial derivatives with respect to time, we need three lemmas modelled after [11], Lemma 3.1 and Thm. 4.1 which in turn are modelled after [5]. Lemma 2.3 yields a kind of (super-) stability result à la [5].

LEMMA 2.3 [[11], Lemma 3.1]: Let \(\rho \in H, \ Q \in (L^2(\Omega))^2, \) and \(q \in L^2(\Omega)\). If \(\tau \in V_N\) satisfies

\[
(\alpha \rho, \chi) - (\text{div} \chi, \tau) + (\beta \tau, \chi) = (Q, \chi), \quad \forall \chi \in H_N,
\]

\[
(\text{div} \rho, v) + \lambda(\tau, v) = (q, v), \quad \forall v \in V_N,
\]

then there exists a constant \(C = C(\alpha, \beta, \lambda, \Omega)\), such that,

\[
\| \tau \|_0 \leq C[p^{-1/2}\| \rho \|_0 + p^{-2}\| \text{div} \rho \|_0 + \| Q \|_0 + \| q \|_0].
\]  

The proof relies on a duality argument (originating in [10]) and coincides with the special case of the proof in [11] (with their \(\theta = 2\)).

The estimates for \(\eta, \rho,\) and \(\text{div} \rho\) are given in [11], here called Lemma 2.4.
LEMMA 2.4 [[11], Theorem 4.1]: Assume that the solution $u$ at any time in $\mathbf{J}$ is in $H^2(\Omega)$. Then there is a positive constant $C$, independent of $p$ such that, for $m \geq 2$

\[
\|u - U\|_0 \leq Cp^{1-m}\|u\|_m, \tag{2.10}
\]
\[
\|\sigma - \Sigma\|_0 \leq Cp^{3/2-m}\|u\|_m, \tag{2.11}
\]
\[
\|\text{div} (\sigma - \Sigma)\|_0 \leq Cp^{2-m}\|u\|_m. \tag{2.12}
\]

Since the regularity requirements are less than those of [11] (where they required $u \in H^{7/2}$ used to bound some nonlinearities) we would like to present a proof.

Proof: Let

\[
\theta = u - P_N u, \quad \varepsilon = \sigma - \Pi_N \sigma, \tag{2.13}
\]
\[
\tau = P_N u - U, \quad \delta = \Pi_N \sigma - \Sigma, \tag{2.14}
\]

then

\[
\eta = u - U = (u - P_N u) + (P_N u - U) = \theta + \tau, \tag{2.15}
\]
\[
\rho = \sigma - \Sigma = (\sigma - \Pi_N \sigma) + (\Pi_N \sigma - \Sigma) = \varepsilon + \delta. \tag{2.16}
\]

To get the estimate for $\eta$ we need only concentrate on one for $\tau$. If we take $\tau = P_N u - U$, $\rho = \sigma - \Sigma$, $Q = (P_N u - u) \beta$, and $q = 0$ in (2.8), we recover a rewriting of (2.4) and (2.5). Hence, by the previous lemma,

\[
\|\tau\|_0 \leq C[p^{-1/2}\|\rho\|_0 + p^{-2}\|\text{div} \rho\|_0 + \|Q\|_0]
\leq C[p^{-1/2}(\|\varepsilon\|_0 + \|\delta\|_0) + p^{-2}(\|\text{div} \varepsilon\|_0 + \|\text{div} \delta\|_0) + \|\theta\|_0]
\leq C[p^{-1/2}(I + II) + p^{-2}(III + IV) + V],
\]

where each of the terms enumerated with an odd roman numeral satisfies

\[
I = \|\varepsilon\|_0 = \|\sigma - \Pi_N \sigma\|_0 \leq Cp^{1/2-r}\|\sigma\|_r \leq Cp^{3/2-m}\|u\|_m, \quad m > 3/2,
\]
\[
II = \|\text{div} \sigma - P_N \text{div} \sigma\|_0 \leq Cp^{-r}\|\text{div} \sigma\|_r \leq Cp^{2-m}\|u\|_m, \quad m \geq 2,
\]
\[
V = \|\theta\|_0 = \|u - P_N u\|_0 \leq Cp^{-m}\|u\|_m, \quad m \geq 0.
\]
For the term $\mathcal{II}$, we state (2.4)-(2.5) once more in our recently introduced notation and split off some terms to the right hand side:

\[
(\alpha\delta, \chi) - (\tau, \text{div} \chi) + (\beta\tau, \chi) = - (\alpha\mathcal{P}, \chi) - (\theta\beta, \chi), \quad \forall \chi \in H_N, \quad (2.17)
\]

\[
(\text{div} \delta, v) + \lambda(\tau, v) = 0, \quad \forall v \in V_N. \quad (2.18)
\]

Now let $\chi = \delta$ and $v = \tau$ in the sum equation (2.17) + (2.18) to obtain

\[
c^\ast (\|\delta\|_0^2 + \|\tau\|_0^2) \leq (\alpha\delta, \delta) + (\beta\tau, \delta) + \lambda(\tau, \tau)
\]

\[
= - (\alpha\mathcal{P}, \delta) - (\theta\beta, \delta)
\]

\[
\leq C(\|\mathcal{P}\|_0 + \|\theta\|_0)\|\delta\|_0,
\]

using coercivity once more so that

\[
\mathcal{II} = \|\delta\|_0 \leq C(\|\mathcal{P}\|_0 + \|\theta\|_0)
\]

\[
\leq C p^{1/2 - r}\|\sigma\|_r + C p^{-m}\|u\|_m
\]

\[
\leq C p^{3/2 - m}\|u\|_m, \quad m > 3/2.
\]

To obtain the last bound, one on $\mathcal{II}$, we take $v = \text{div} \delta$ in (2.18),

\[
\mathcal{IV} = \|\text{div} \delta\|_0 \leq C\|\tau\|_0
\]

\[
\leq C(\|\mathcal{P}\|_0 + \|\theta\|_0^{1/2}(\|\delta\|_0))^{1/2}
\]

\[
\leq C p^{3/2 - m}\|u\|_m, \quad m > 3/2.
\]

using the bounds above involving $\|\delta\|_0$. □

**Remark 2.5:** We note that (2.12) is sharp, given the regularity or shift inequalities: $\|\text{div} \sigma\|_{m - 2} \leq C\|\sigma\|_{m - 1} \leq C\|u\|_m$ ($m \geq 2$). Regarding (2.11), since we employ an estimate of a term like $\|\mathcal{P}\|_0$ involving the Raviart-Thomas projection for which the estimate (2.3) will be proven to be sharp, we could not expect a better bound that (2.11). One may actually formulate (2.10) differently with the highest order term on the right hand side being $C p^{-r}\|\sigma\|_r$, — stemming from estimating the term I by (2.3), involved in our use of the super-stability lemma above (with only a half mitigating power of $p$) — (other terms being bounded by $(C p^{-m}\|u\|_m$), for which we can hope no better. That would require an improved version of Lemma 2.3.

We now give estimates for $\eta_r$, $\rho_r$, and $\text{div} \rho_r$. 

M³ AN Modélisation mathématique et Analyse numérique
Mathematical Modelling and Numerical Analysis
Lemma 2.6: Assume that the solution $u$ and its partial time derivative $u_t$ are in $H^2(\Omega)$ for all $t \in J$. Then there is a positive constant $C$, independent of $p$ such that, for $m \geq 2$

$$\|u_t - U_t\|_0 \leq C p^{3/2-m}(\|u\|_m + \|u_t\|_m),$$

$$\|\sigma_t - \Sigma_t\|_0 \leq C p^{3/2-m}(\|u\|_m + \|u_t\|_m),$$

$$\|\text{div} (\sigma_t - \Sigma_t)\|_0 \leq C p^{3/2-m}(\|u\|_m + \|u_t\|_m).$$

Proof: Rewriting (2.4) and (2.5) using the nomenclature introduced in (2.7) yields:

$$(\alpha \rho, \chi) - (\text{div} \chi, \eta) + (\beta \eta, \chi) = 0, \quad \forall \chi \in H_N,$$

$$(\text{div} \rho, v) + \lambda(\eta, v) = 0, \quad \forall v \in V_N.$$

Now, differentiate the above two equations with respect to time (taking $\chi$ and $v$ to be independent of time):

$$(\alpha \rho_t, \chi) - (\text{div} \chi, \eta_t) + (\beta \eta_t, \chi) = -(\alpha_t \rho, \chi) - (\beta_t \eta, \chi), \quad \forall \chi \in H_N,$$

$$(\text{div} \rho, v) + \lambda(\eta, v) = 0, \quad \forall v \in V_N,$$

noting that this operator ($\partial/\partial t$) commutes with the spatial operators $P_N$, $\Pi_N$ and $\text{div}$ (e.g. $((P_N v)_t = P_N v_t)$ and that

$$(\text{div} \chi, \theta_t) = (v, \theta_t) = 0, \quad \forall \chi \in H_N, \quad \forall v \in V_N,$$

$$(\text{div} \varphi, v) = (\text{div} \varphi, v) = 0, \quad \forall v \in V_N.$$}

To estimate $\eta_t$, it suffices to bound $\tau_t$, since $\eta_t = \tau_t + \theta_t$ and $\theta_t$ can be bounded using (2.1). Observe that

$$(\alpha \delta_t, \chi) - (\text{div} \chi, \tau_t) + (\beta \tau_t, \chi) = -(\alpha \varphi_t, \chi) - (\alpha_t \rho, \chi)$$

$$- (\beta_t \eta, \chi) - (\beta \theta_t, \chi), \quad \forall \chi \in H_N,$$

$$(\text{div} \delta_t, v) + \lambda(\tau_t, v) = 0, \quad \forall v \in V_N.$$  \hspace{1cm} (2.19)

Take $\chi = \delta_t$ and $v = \tau_t$ in these last two equations and add them up to get:

$$(\alpha \delta_t, \delta_t) + \lambda \|\tau_t\|_0^2 + (\beta \tau_t, \delta_t) = -(\alpha \varphi_t, \delta_t) - (\alpha_t \rho, \delta_t)$$

$$- (\beta_t \eta, \delta_t) - (\beta \theta_t, \delta_t).$$

vol. 31, n° 3, 1997
Using coercivity we get
\[ \| \delta_t \|_0 + \| \tau_t \|_0 \leq C ( \| \partial_t \|_0 + \| \rho \|_0 + \| \eta \|_0 + \| \theta_t \|_0 ). \]

It also follows from (2.19) and the fact that \( \text{div} \delta_t \in V_N \) that
\[ \| \text{div} \delta_t \|_0 \leq \lambda \| \tau_t \|_0 . \]

Now,
\[ \| \eta_t \|_0 \leq \| \theta_t \|_0 + \| \tau_t \|_0 = \| u_t - P_N u_t \|_0 + \| \tau_t \|_0, \]
\[ \| \rho_t \|_0 \leq \| \partial_t \|_0 + \| \delta_t \|_0 = \| \sigma_t - P_N \sigma_t \|_0 + \| \delta_t \|_0, \]
\[ \| \text{div} \rho_t \|_0 \leq \| \text{div} (\sigma - P_N \sigma) \|_0 + \lambda \| \tau_t \|_0. \]

These inequalities suffice to prove the assertion of Lemma 2.6. \( \square \)

3. TRANSIENT ERROR ANALYSIS

In this section we first present the \( L^2 \) and \( L^\infty \)-error estimates for \( \zeta = \Sigma - \sigma_N \) and \( \xi = U - u_N \).

**Proposition 3.1**: Let \( u \) and \( u_t \in L^2(H^m) \) for \( m \geq 2 \) where \( u \) is the solution of (1.1), and let \((u_N, \sigma_N)\) and \((U, \Sigma)\) be as defined in (1.6-1.8) and (2.4-2.5), respectively. Let \( (\zeta, \xi) = (U, \Sigma) - (u_N, \sigma_N) \). Then there is a positive constant \( C \), independent of \( p \) such that, for \( m \geq 2 \),
\[ \| \zeta \|_{L^\infty(L^2)} + \| \xi \|_{L^\infty(L^2)} \leq C p^{3/2 - m} ( \| u \|_{L^\infty(H^m)} + \| u_t \|_{L^\infty(H^m)} ). \]

**Proof**: Subtracting (2.4, 2.5) and (1.6, 1.7) from (1.3, 1.4) yields:
\[ (\alpha \zeta, \chi) - (\xi, \text{div} \chi) + (\beta \xi, \chi) = 0 , \quad \chi \in H_N, \]
\[ (c (u_t - u_N, t), v) + (\text{div} \zeta, v) + \lambda (\xi, v) = \lambda (\eta, v) + \lambda (\xi, v), \quad v \in V_N, \]
then (3.1) becomes
\[ \chi = \Sigma - \sigma_N = \zeta, \quad \text{and} \quad v = U - u_N = \xi, \]

**M^2 AN Modélisation mathématique et Analyse numérique**
**Mathematical Modelling and Numerical Analysis**
add them up to get

\[ \frac{1}{2} \frac{d}{dt} (c \xi, \xi) + (\alpha \xi, \xi) + (\beta \xi, \xi) + \lambda(\xi, \xi) = \]

\[ \frac{1}{2} (c_t \xi, \xi) - (c \eta_t, \xi) + \lambda(\eta, \xi) + \lambda(\xi, \xi). \]

Bound the terms on the right hand side by the Cauchy-Buniakowsky-Schwarz inequality, integrate with respect to time, observing that \( u_N(0) = U(0) \), and employ the Gronwall inequality to get

\[ \| \xi(t) \|_0^2 + \| \xi \|_{L^2(L^2)}^2 + \| \xi \|_{L^2(L^2)}^2 \leq C( \| \eta_t \|_{L^2(L^2)}^2 + \| \eta \|_{L^2(L^2)}^2 ). \]  

(3.3)

where \( C \) then depends on \( t \).

Next, we give an estimate for \( \| \zeta(t) \|_0^2 \). Use (3.2) with \( v = \xi_t \) to obtain

\[ (c \xi_t, \xi_t) + (\text{div} \xi, \xi_t) + \lambda(\xi, \xi_t) = - (c \eta_t, \xi_t) + \lambda(\eta, \xi_t) + \lambda(\xi, \xi_t) \]  

(3.4)

and differentiate throughout (3.1) with respect to \( t \):

\[ (\alpha \zeta_t, \chi) - (\xi_t, \text{div} \chi) + \left( \frac{\partial}{\partial t} (\beta \xi), \chi \right) = - (\alpha_t \xi, \chi) \]  

(3.5)

(with \( \chi \) independent of time). Now choose \( \chi = \xi(t) \) in the sum of (3.4) and (3.5), then a short calculation yields the following identity at an arbitrary \( t \):

\[ (c \xi_t, \xi_t) + \frac{1}{2} \frac{d}{dt} \{ (\alpha \xi, \xi) + \lambda(\xi, \xi) + (\beta \xi, \xi) \} = \]

\[ - (c \eta_t, \xi_t) + \lambda(\eta, \xi_t) + \lambda(\xi, \xi_t) - \frac{1}{2} \{ (\alpha_t, \xi, \xi) + \]

\[ + (\beta \xi, \xi_t) - (\partial(\beta \xi)/\partial t, \xi) \}. \]  

(3.6)

We proceed to bound each term on the right-hand-side of (3.6) in turn:

\[ |(c \eta_t, \xi_t)| \leq C \| \eta_t \|_0^2 + \epsilon \| \xi_t \|_0^2 \]
with the two terms containing a factor $\lambda$ majorizable in a very similar fashion (also using (3.3)), and further in (3.6),

$$
| (\alpha_t, \zeta) | \leq \| \alpha_t \| \| \zeta \|_0^2
$$

$$
\left| \int_0^t (\beta \zeta, \zeta) \, dt \right| = \left| \left( \int_0^t \beta \zeta, \zeta \, dt, 1 \right) \right|
$$

$$
= \left| - \left( \int_0^t (\beta \zeta), \zeta \, dt, 1 \right) \right| + \left| \left( \beta \zeta, \zeta \right)_0 \right|
$$

$$
= \left| - \int_0^t \left( (\beta \zeta), \zeta \right) \, dt + (\beta \zeta, \zeta)(t) \right| , \text{ where}
$$

$$
| (\beta \zeta, \zeta)(t) | \leq C_\epsilon \| \zeta(t) \|_0^2 + \epsilon \| \zeta(t) \|_0^2 , \text{ and lastly}
$$

$$
| (\partial (\beta \zeta) / \partial t, \zeta) | \leq C_\epsilon \| \zeta \|_0^2 + \epsilon \| \zeta \|_0^2 + C \| \zeta \|_0^2 .
$$

In the second estimation we used integration in time over the interval $(0, t)$ — which we will perform on all the terms of (3.6) in a moment — here we did it by parts and used that $\xi(0) = (U - u_N)(0) = 0$ by (1.8).

Integrating (3.6) with respect to time from 0 to $t$ and applying coercivity we get

$$
\| \xi_t \|_{L^2(L^2)}^2 + \| \xi(t) \|_0^2 + \| (\zeta(t)) \|_0^2 \leq
$$

$$
C_\epsilon \| \eta \|_{L^2(L^2)}^2 + \epsilon C \| \xi_t \|_{L^2(L^2)}^2 + C_\epsilon \| \xi \|_{L^2(L^2)}^2 + C \| \zeta(0) \|_{L^2(L^2)}^2
$$

$$
+ C_\epsilon \| \eta \|_{L^2(L^2)}^2 + (\| \alpha_t \|_{L^\infty(L^\infty)} + C_\epsilon ) \| \zeta \|_{L^2(L^2)}^2 + C_\epsilon \| \zeta(t) \|_0^2 + \epsilon \| \zeta(t) \|_0^2 .
$$

Note that $\| \zeta(0) \|_0^2 = 0$ due to the facts $\xi(0) = 0$ and that we may take $\chi = \zeta(0)$ in (3.1). Using (3.3) we get

$$
\| \xi \|_{L^\infty(L^\infty)}^2 + \| \zeta \|_{L^2(L^2)}^2 \leq C ( \| \eta \|_{L^2(L^2)}^2 + \| \eta_t \|_{L^2(L^2)}^2 ) . \quad (3.7)
$$

Using previous lemmas in (3.7), one obtains the inequality stated in the proposition. \hfill \Box
We may now state and prove our main result regarding estimates for the semi-discrete problem in time:

**Theorem 3.2**: Let \( u \) and \( u_t \in L^2(H^m) \) for \( m \geq 2 \) and let \( (u, \sigma) \) and \( (u_N, \sigma_N) \) be as defined in (1.1) and (1.6-1.8), respectively. Then there is a positive constant \( C \), independent of \( p \) such that, for \( m \geq 2 \)

\[
\| u - u_N \|_{L^\infty(L^2)} + \| \sigma - \sigma_N \|_{L^\infty(L^2)} \leq Cp^{3/2 - m}( \| u \|_{L^2(H^m)} + \| u_t \|_{L^2(H^m)}) .
\]

**Proof**: The proof follows directly from the previous lemmas.

**Remark 3.3**: For the equation in (1.1) of parabolic type, one may well hope that parabolic smoothing will occur so that \( u(\cdot, t) \) and \( u_t(\cdot, t) \) will be rather smooth (read lie in \( H^m(\Omega) \) for \( m \gg 2 \)). If this is indeed the case, the error estimate in Thm. 3.2 will yield superior rate of convergence for the error as compared to an \( h \) version with a fixed \( p \) once an initial transient has passed by.

4. \( p \)-Stability of Mixed Method Spatial Discretizations and a Lower Bound for the Raviart-Thomas Projection

In this section we delve a little more into the discretization of the elliptic problem. Since it is important for existence, uniqueness and error estimations for the elliptic problem to have elements that satisfy the general requirements in the saddle-point framework of [1] and [2], we will prove certain norm estimates for a right inverse of the divergence operator in \( \mathcal{B}(L^2, H(\text{div})) \) acting between the discrete subspaces. We shall then use this to prove stability of the Brezzi-Douglas-Marini subspaces and the very same technique is valid for the Raviart-Thomas case. We conclude with a proof that one cannot in general improve on (2.3).

Let (for the purposes of simple \( L^2 \)-orthogonality as before) \( \Omega \) be partitioned into parallelograms \( E \in \mathcal{T}_N \) affinely mapped onto \( R = (-1, 1)^2 \) by \( F_E \). We introduce the finite dimensional subspaces of \( V \) and \( H \):

\[
V_N^{BDM} = \{ v \in L^2(\Omega) : v|_E \circ F_E^{-1} \in \mathcal{P}^{p-1}, \forall E \in \mathcal{T}_N \}
\]

\[
H_N^{BDM} = \{ \chi \in H(\text{div}, \Omega) : \chi|_E \circ F_E^{-1} \in (\mathcal{P}^p \times \mathcal{P}^p) \oplus \text{span } \{(x^{p+1}, -x^p y)^T, (xy^p, -y^{p+1})^T)\} \}
\]

where \( \mathcal{P}^p \) is the set of polynomials (in two variables \( x \) and \( y \)) of total degree at most \( p \).
In order to have hope for quasi-optimal error estimates for a mixed finite element method based on these spaces, for a saddle point formulation of the spatial problem, it is necessary to investigate the question of stability: Does there exist a sequence of positive numbers $\gamma_{BDM}(p)$ satisfying

$$\min_{v_N \in V_N^{BDM}} \max_{\tau_N \in H_N^{BDM}} \frac{(v_N \nabla \cdot \tau_N)_\Omega}{\|v_N\|_{L^2(\Omega)} \|\tau_N\|_{H(\text{div})}} = \gamma_{BDM}(p)$$  \hspace{1cm} (4.1)$$

that is bounded uniformly from below? Note the formal resemblance with the inf-sup constant present in $p$-discretizations of Stokes problem and that we again desire to invert the divergence operator but now in $\mathcal{B}(L^2, H(\text{div}))$ (in lieu of $H^1$ as was the case in [8]).

Let $(\nabla \cdot)^{-1}: V_N^{BDM} \rightarrow H_N^{BDM}, p \geq 1$, be the operator which associates to any $q \in V_N^{BDM}$ one of the — clearly many — choice of $\chi \in H_N^{BDM}$ of minimal $\|\cdot\|_N$-norm satisfying $\nabla \cdot \chi = q$.

**Proposition 4.1:** The operator $(\nabla \cdot)^{-1}: V_p^{BDM} \rightarrow H_p^{BDM}, p \geq 1$, considered as an operator from a subspace of $L^2(R)$ to a subspace of $H(\text{div})$ satisfies

$$\| (\nabla \cdot)^{-1} \|_{\mathcal{B}(L^2, H(\text{div}))} \leq C$$

with a positive constant $C$ independent of $p$.

Before we prove this proposition, allow us to note some properties of Legendre polynomials; cf. [14] or [17].

Denote by $\ell_n^2$, the $n$-th Legendre polynomial (with point value $+1$ at $+1$) of degree $n$ and $L^2$-norm:

$$\int_{-1}^{1} \ell_n^2 dx = \frac{2}{2n+1}.$$ \hspace{1cm} (4.2)

By induction and $L^2$-orthogonality,

$$\int_{-1}^{x} \ell_n(r) \, dr = \frac{1}{2n+1} (\ell_{n+1}(x) - \ell_{n-1}(x)), \text{ for } n \geq 1.$$  \hspace{1cm} (4.3)

These two identities yield the following inequality:

$$\left\| \sum_{m, n \in \mathcal{S}} \alpha_{mn} \left( \int_{-1}^{x} \ell_m(y) \right) \ell_n(y) \right\|_{L^2(R)} \leq C \sum_{m, n \in \mathcal{S}} \alpha_{mn}^2 \frac{1}{(m+1)^3} \frac{1}{n+1}$$ \hspace{1cm} (4.4)
if the right-hand-side converges (e.g., if $f$ if finite) and where $C$ is independent of $f$.

Proof of Proposition 4.1: Fix an $E \in \mathcal{T}_N$ and denote, for simplicity’s sake, $q^{(E)} = q\big|_E F^{-1}_A$, as an example. For any given $q^{(E)} \in \mathcal{P}^{p-1}$, there exist $\{\alpha_{mn}\}$ such that

$$q^{(E)} = \sum_{m,n \geq 0} \alpha_{mn} \ell_m(x) \ell_n(y). \quad (4.5)$$

Let

$$\chi^{(E)} = \begin{bmatrix} \sum_{m>n} \alpha_{mn} \left( \int_{-1}^{x} \ell_m \right) \ell_n(y) \\ \sum_{m \leq n} \alpha_{mn} \ell_m(x) \left( \int_{-1}^{y} \ell_n \right) \end{bmatrix}.$$

Then $\nabla \cdot \chi^{(E)} = q^{(E)}$. So

$$\| \nabla \cdot \chi^{(E)} \|_0 = \| q^{(E)} \|_0,$$

$$\| q^{(E)} \|_0^2 = \sum_{m,n} \alpha_{mn}^2 \frac{1}{(m+1)} \frac{1}{(n+1)},$$

and, from (4.2)-(4.4),

$$\| \chi_1^{(E)} \|_0^2 \leq C \sum_{m>n} \alpha_{mn}^2 \frac{1}{(m+1)} \frac{1}{(n+1)} \leq C \| q^{(E)} \|_0^2$$

with a similar estimation for $\chi_2^{(E)}$ proving the uniform bound sought in the case of only one element. Note that $\chi^{(E)} \cdot v = 0$ for $x = \pm 1$ and also for $y = -1$. At $y = +1$, $\chi^{(E)} \cdot v = \alpha_{00}$, a constant. Further, if we exclude the one term $\alpha_{00}$ in $q^{(E)}$ and hence in $\chi_2^{(E)}$, also $\chi^{(E)} \cdot v = 0$ for $y = +1$.

Accordingly, in the case of multiple elements, where we have to construct $\chi \in H$ with normal components continuous across inter-element boundaries, we split

$$q = q_0 + q_+ \quad \text{with} \quad q_0^{(E)} = \alpha_{00} \ell_0 \ell_0$$

and $q_+^{(E)}$ of the form (4.5) with $(m,n) \neq (0,0)$. For $q_+$ we see $\chi_+$ constructed as above, when pieced together does indeed belong to $H(\text{div})$. vol. 31, n° 3, 1997
(since $\chi_+^{(E)} \cdot v = 0$ for $x = \pm 1$ and $y = \pm 1$). For $q_0$ which is discontinuous and piecewise constant, there exists — by the following lemma, e.g. — a $\chi_0 \in \{ v \in H : v^{(E)} \in [Q^2]^2 \}$ such that $\nabla \cdot \chi_0 = q_0$ and $\chi_0 \cdot v$ is continuous across inter-element boundaries. Also, $\| \chi_0 \|_H \leq C \| q \|_0$. In conclusion, $\chi_0 + \chi_+$ satisfies the requirements.

The next Lemma is actually a simple consequence of the well-known (among Stokes people) divergence stability of $( [Q^2]^2, Q^0 )$ on parallelogram elements, cf. Example 11.1 in [9]. We include a very simple proof sufficing for our purposes.

**Lemma 4.2** : Let $q_0$ be discontinuous and piecewise constant on each element $E$ of $\mathcal{T}_N$ — a partitioning of $\Omega$ into parallelograms. Then there exists a $\chi_0 \in \{ v \in H : v^{(E)} \in [Q^2]^2 \}$ such that $\nabla \cdot \chi_0 = q_0$ and $\chi_0 \cdot n$ is continuous across inter-element boundaries. Furthermore, $\| \chi_0 \|_H \leq C \| q_0 \|_0$.

**Proof** : We meet the objective by a simple counting argument. $[Q^2]^2$ has $18 (= 2 \times 3^2)$ degrees of freedom for which we use at most $6( = 4 \times 3 \times 1/2 )$ to ensure the continuity of $\chi_0 \cdot n$ on the four sides of $E$ whereas $\text{div} \chi_0 = q_0$ requires 8 linear equations. Choosing a $\chi_0$ of minimal $H$-norm, ensures the norm bound with a $C$ independent of $p$. Note that $\mathcal{Q}^2 \subset \mathcal{P}^4$.

**Corollary 4.3** : With the above, there exists $\gamma > 0$ independent of $p$ such that

$$\gamma^{\text{BDM}}(p) > \gamma$$

i.e., the Brezzi-Douglas-Marini elements are $p$-stable.

**Proof** : It follows directly from the norm estimate in the previous proposition and the form of the inf-sup constant.

**Remark 4.4** : This establishes that the Brezzi-Douglas-Marini elements are stable also with respect to $p$ and improves on the statement of a lower bound $\gamma^{\text{BDM}}(p) \geq c \epsilon p^{-1}$ proved earlier in [16], Thm. 4.1. Our reason for not pursuing BDM-elements further in this paper — despite the comparatively smaller number of degrees of freedom — is that we do not know how to improve on the projection estimate in [16], Lemma 3.3 where one loses a whole power in $p$ (as opposed to only 1/2 in (2.3)) relative to the $L^2$ projection.

The case of Raviart-Thomas elements, [13] may be handled in a very similar way.

**Proposition 4.5** : The operator $(\nabla \cdot)^{-1} : V_N \to H_N$, $p \geq 1$, considered as an operator from a subspace of $L^2$ to a subspace of $H(\text{div})$ satisfies

$$\| (\nabla \cdot)^{-1} \|_{H(L^2, H(\text{div}))} \leq C$$
with a positive constant $C$ independent of $p$.

**Corollary 4.6:** With the above, there exists $\gamma > 0$ independent of $p$ such that

$$\gamma(p) > \gamma$$

i.e., the Raviart-Thomas elements are $p$-stable.

**Remark 4.7:** This is the same result as in [16], Thm. 4.1, but with an alternate (perhaps simpler) proof.

**Lemma 4.8:** There exist $\chi_* \in H \cap H'$ with $r > 1$ for which their Raviart-Thomas projection onto $H_N$ given by (2.2), $\Pi_N \chi_*$, satisfy the following estimate:

$$\| \Pi_N \chi_* - \chi_* \|_0 \geq c_* p^{3/2 - 2r} (\log p)^{1/2},$$

(4.6)

where $c_* > 0$ is a constant independent of $p$ but depending on $\chi_*$.  

**Proof:** Let

$$\chi_* = \left[ \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \alpha_{m,n} \ell_m(x) \ell_n(y) \right] \begin{array}{c} \vdots \\ 0 \end{array}$$

and let

$$\Pi_N \chi_* = \begin{bmatrix} \sum_{m=0}^{p+1} \sum_{n=0}^{p} \tilde{\alpha}_{m,n} \ell_m(x) \ell_n(y) \\ \sum_{m=0}^{p+1} \sum_{n=0}^{p} \tilde{\beta}_{m,n} \ell_m(x) \ell_n(y) \end{bmatrix}.$$  

From [11], identities (2.5)-(2.7), it follows easily that $\tilde{\beta}_{m,n} = 0$ for all $m, n$ and that

$$\tilde{\alpha}_{m,n} = \alpha_{m,n}, \quad 0 \leq m \leq p - 1, \quad 0 \leq n \leq p,$$

$$\tilde{\alpha}_{p,n} = \sum_{m=0}^{\infty} \alpha_{2m+p, n}, \quad \tilde{\alpha}_{p+1,n} = \sum_{m=0}^{\infty} \alpha_{2m+p+1, n}, \quad 0 \leq n \leq p.$$
One then may compute that

\[
\| \chi_* - \Pi_N \chi_* \|_0^2 = \sum_{m=p}^{p+1} \sum_{n=0}^{p} \frac{4(\alpha_{m,n} - \tilde{\alpha}_{m,n})^2}{(2m+1)(2n+1)}
\]

\[
+ \sum_{m=p+2}^{\infty} \sum_{n=0}^{p} \frac{4(\alpha_{m,n})^2}{(2m+1)(2n+1)}
\]

\[
+ \sum_{m=0}^{\infty} \sum_{n=p+1}^{\infty} \frac{4(\alpha_{m,n})^2}{(2m+1)(2n+1)}
\]

\[= I + II + III.\]

As in [11] (or [16]), II & III can be bounded better than (2.3):

\[
II + III \leq C p^{-2r} \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{(\alpha_{m,n})^2(1 + m^2 + n^2)^r}{(2m+1)(2n+1)}, \quad r \geq 0
\]

\[
\leq C p^{-2r} \| \chi \|_r^2,
\]

by [3]. We may verify that

\[
I = \frac{4}{2p+1} \sum_{n=0}^{p} \left( \frac{\sum_{m=1}^{\infty} \alpha_{2m+p,n}}{2n+1} \right)^2 + \frac{4}{2p+3} \sum_{n=0}^{p} \left( \frac{\sum_{m=1}^{\infty} \alpha_{2m+p+1,n}}{2n+1} \right)^2
\]

Now let us choose, for a given \( r > 1, \)

\[
\alpha_{m,n}^* = (1 + m^2 + n^2)^{-r}(1 + 2m), \quad m, n \geq 0.
\]

A straightforward calculation confirms that \( \chi_* = \sum_{m,n} \alpha_{m,n}^* \ell_m \ell_n \in H'. \) With this choice, we also readily verify that
\[
\sum_{m=1}^{\infty} \alpha_{m+p,n}^2 = \sum_{m=1}^{\infty} \left( 1 + (2m + p)^2 + n^2 \right)^r (1 + 2(2m + p)) \\
= \sum_{i=p+2, i \text{ even}}^{\infty} (1 + i^2 + n^2)^r (1 + 2i) \quad \text{[with } 0 \leq n \leq p \text{]} \\
\geq \sum_{i=p+2, i \text{ even}}^{\infty} (1 + i^2 + p^2)^r (2i) \\
\geq \int_{p+4}^{\infty} (1 + x^2 + p^2)^r (2x) \, dx \\
\geq \int_{1+(p+4)^2 + p^2}^{\infty} t^{-r} \, dt \\
\geq c p^{2-r},
\]
so that
\[
I \geq c p^{-1} p^{4-4r} \sum_{n=0}^{p} \frac{1}{2n+1} \geq c_{\gamma} p^{3-4r} \log p,
\]
which proves the assertion of the lemma.

**Corollary 4.8**: The estimate (2.3) is sharp, i.e. there cannot be an estimate in its stead of the form:

\[
\|\Pi_N \chi - \chi\|_0 \leq c_{\gamma} p^{\kappa-r} \quad r > 1, \quad \kappa < 1/2,
\]
with \(C_{\gamma}\) independent of \(p\) that is valid for general \(\chi \in H^r, r > 1\).

**Proof**: Such an estimate would, when combined with the lower estimate in the previous lemma, yield \(((\log p)^{1/2} p^{(3/2-\kappa)-r}) \leq C_{\gamma}\). Since \(\kappa < 1/2, 3/2 - \kappa > 1\) and we could choose \(r\) to satisfy \(1 < r < 3/2 - \kappa\) to obtain a contradiction.

In this final portion of the section we describe two ways in which one could extend the results in this paper: one is that it is possible to treat curved domains and also having triangles in the geometric decomposition of the domain as long as they border the boundary. Another is a new mixed method projection which we will describe by ways of an example.

**Remark 4.9**: Suppose \(\hat{K}\) is a triangle bordering \(\partial \Omega\), which may be mapped affinely onto the triangle \(T\) below by the affine mapping \(F_{\hat{K}}\)
with the vertices as given and one curved side lying entirely within the unit square $S = [0, 1]^2$. The curved side of $\tilde{K}$ is assumed to be a part of $\partial \Omega$.

For our discrete spaces, we now insist that

$$\chi|_{\mathcal{K}} \in Q^{r+1}, p \times Q^{p,p+1}$$

and

$$v|_{\mathcal{K}} \in Q^p$$

as well as the continuity of normal components of functions $\chi$ across inter-element boundaries with $\tilde{K}$. (Note that this is richer than the usual Raviart-Thomas triangular éléments.)

We extend the construction of $(\nabla \cdot)^{-1}$ given in Prop. 4.1 to such an element by,

for arbitrary $q_{\mathcal{K}} \in Q^p$, let

$$\chi_{\mathcal{K}} = \begin{pmatrix} \int_0^x q(s, t) \, ds \\ 0 \end{pmatrix} = \begin{pmatrix} \chi_1 \\ 0 \end{pmatrix}.$$  

Observe that $\chi_{\mathcal{K}} \in Q^{r+1}, p \times Q^{p,p+1}$, $\nabla \cdot \chi_{\mathcal{K}} = q_{\mathcal{K}}$ and that $\chi_{\mathcal{K}} \cdot v = 0$ on the two straight edges of $T: (0, 1) \times \{0\}$ and $\{0\} \times (0, 1)$. Thus $\chi_{\mathcal{K}}$, as constructed here, will match with $\chi_{\mathcal{K}}$, as constructed earlier in Prop. 2.1 having vanishing normal components on inter-element boundaries. Also,

$$\|\nabla \cdot \chi\|_{0,T} = \|q\|_{0,T}$$

and, by the Poincaré-Friedrichs inequality,

$$\|\chi\|_{0,T} = \|\chi_1\|_{0,T} \leq \|\chi_{1,x}\|_{0,T} = \|q\|_{0,T}$$

guaranteeing that we may extend the uniform bound on the operator norm of $(\nabla \cdot)^{-1}$ to include curved boundary triangles.
We conclude this remark by showing that one may extend the Raviart-Thomas projection to this case and that the error-estimate (2.3) for the Raviart-Thomas projection remains valid. Note that there exists an extension operator $E$ such that $\forall \chi \in H'(T)$, $\exists \chi \in H'(S)$ with

$$\| E\chi \|_{r,S} \leq C \| \chi \|_{r,T},$$

cf. Theorem 5 in Stein's monograph [15]. Then we define the extended Raviart-Thomas projection to be $\tilde{\Pi}_N \chi = \Pi_N E\chi |_T$ so that

$$\| \tilde{\Pi}_N \chi - \chi \|_{0,T} = \| \Pi_N E\chi - E\chi \|_{0,T} \leq \| \Pi_N E\chi - E\chi \|_{0,S} \leq C p^{1/2-r} \| \chi \|_{r,S} \quad \text{[by (2.3)]} \leq C p^{1/2-r} \| \chi \|_{r,T}$$

so that boundary triangles with one curved side (along $\partial \Omega$) are allowed.

**Example 4.10**: We now construct another mixed method projection $A_N$ with some of the same properties as the Raviart-Thomas projection but with better error estimates. We will take — as an example — the instance of one element: let $\Omega$ be a triangle or a rectangle and let $a = 1$ and $b = g = 0$.

Let $\Phi_N \subseteq Q^{p+1} \cap H^1_0(\Omega)$ and define the discrete spaces $V_N = \Delta \Phi_N$ and $H_N = \nabla \Phi_N$. Clearly

$$\Phi_N \xrightarrow{\nabla} V_N \xrightarrow{\Delta} \Phi_N$$

So that boundary triangles with one curved side (along $\partial \Omega$) are allowed.

Suppose $u \in L^2$ and let $\sigma = \nabla u \in H(\text{div})$, so that $\text{div} \sigma = \Delta u \in L^2$ and $P_N \text{div} \sigma = P_N \Delta u \in V_N$ and take $P_N$ to be the $L^2$ projection onto $V_N$. Let $\phi$ solve

$$\Delta \phi = P_N \Delta u \text{ in } \Omega$$

$$\phi = 0 \text{ on } \partial \Omega$$
Then define

\[ A_N \sigma \overset{\text{def}}{=} \nabla \phi \]  

(4.9)

and we observe the crucial commutative property:

\[ \text{div} \ A_N \sigma = P_N \text{div} \sigma, \quad \forall \sigma \in H(\text{div}). \]

By elliptic estimates, we have the shift inequalities:

\[ \| \nabla \phi \|_s \leq \| \phi \|_{s+1} \leq C \| \Delta \phi \|_{s-1} \quad \text{for} \quad s = 0, 1. \]

This immediately implies that the new projection is stable in \( H^1 \) (but, due to the inverse inequality, not necessarily in \( L^2 \)):

\[ \| A_N \sigma \|_1 = \| \nabla \phi \|_1 \leq C \| P_N \Delta u \|_0 \leq C \| \Delta u \|_0 \leq C \| \sigma \|_1 \]

as well as the error estimates:

\[ \| \sigma - A_N \sigma \|_1 \leq \| \nabla u - \nabla \phi \|_1 \]
\[ \leq \| u - \phi \|_2 \]
\[ \leq \| \text{div} \sigma - P_N \text{div} \sigma \|_0 \]
\[ \leq C \rho^{-r} \| \text{div} \sigma \|_r \]

using that

\[ \| v - P_N v \|_0 = \| \Delta (v - \phi) \|_0 \leq \| v - \phi \|_2 \leq C \rho^{-r} \| v \|_{r+2} \leq C \rho^{-r} \| v \|_r. \]

We also get the quasi-optimal \( L^2 \) estimate which improves upon (2.3):

\[ \| \sigma - A_N \sigma \|_0 \leq \| \nabla u - \nabla \phi \|_0 \]
\[ \leq \| u - \phi \|_1 \]
\[ \leq \| \text{div} \sigma - P_N \text{div} \sigma \|_{-1} \]
\[ \leq C \rho^{-r-1} \| \text{div} \sigma \|_{-1} \]
\[ \leq C \rho^{-r} \| \sigma \|_s \]
THE $p$ VERSION OF MIXED FINITE ELEMENT METHODS

using $s = r + 1$ and the quasi-optimality result:

$$
\| v - P_N v \| = \sup_{w \in H_0^1} \frac{(v - P_N v, w)}{\| w \|_1} \\
= \sup_{w \in H_0^1} \inf_{\omega \in V_0} \frac{(v - P_N v, w - \omega_N)}{\| w \|_1} \\
\leq \sup_{w \in H_0^1} \inf_{\omega \in V_0} \left( \| v - P_N v \|_0 \| w - \omega_N \|_0 / \| w \|_1 \right) \\
\leq C p^{-1} \| v - P_N v \|_0
$$

as there exists $\omega_N \in V_N$ so that $\| w - \omega_N \|_0 \leq C p^{-1} \| w \|_1$.
