

A MATCHING OF SINGULARITIES IN DOMAIN DECOMPOSITION METHODS FOR REACTION-DIFFUSION PROBLEMS WITH DISCONTINUOUS COEFFICIENTS

CHOKRI CHNITI¹

Abstract. In this paper we certify that the same approach proposed in previous works by Chniti *et al.* [*C. R. Acad. Sci.* **342** (2006) 883–886; *CALCOLO* **45** (2008) 111–147; *J. Sci. Comput.* **38** (2009) 207–228] can be applied to more general operators with strong heterogeneity in the coefficients. We consider here the case of reaction-diffusion problems with piecewise constant coefficients. The problem reduces to determining the coefficients of some transmission conditions to obtain fast convergence of domain decomposition methods. After explaining the theoretical results, we explicitly compute the coefficients in the transmission boundary conditions. The numerical results presented in this paper confirm the optimality properties.

1. INTRODUCTION

In this paper we consider an elliptic equation with highly heterogeneous coefficients

$$\begin{cases} -\nabla \cdot (\nu(x)\nabla u) + \eta(x)u = f & \text{in } \Omega \subset \mathbb{R}^2, \\ u = 0 & \text{on } \gamma, \\ \frac{\partial u}{\partial n} = g & \text{on } \partial\Omega \setminus \gamma, \end{cases} \quad (1.1)$$

where $\gamma \subset \partial\Omega$ corresponds to the piece of the boundary with Dirichlet boundary condition. This equation is used for the numerical modelling of the so-called skin problem that describes penetration of drugs through the skin [8]. To simplify the model we choose Ω as a fragment with one cell with a lipid layer (see Fig. 1). Typical feature for the skin problem is the highly heterogeneous coefficients: the penetration coefficient inside the cells is very small, but it is relatively large in the lipid layer. In this paper we consider this problem with the domain Ω decomposed into two subdomains, and we restrict our attention to the case where $\gamma = \partial\Omega$. For large numerical computations with these problems, domain decomposition is a natural idea, a non-overlapping decomposition being directly induced by the different materials. We study in this paper the influence of the transmission conditions on the Schwarz algorithm for reaction-diffusion problems. We numerically test improved transmission conditions with second-order tangential derivatives, which were derived from an asymptotic analysis of the Schwarz algorithm

Keywords and phrases. Corner singularity, domain decomposition method, Kondratiev theory.

FIGURE 1. A skin fragment consisting of one cell (Ω_1) and a lipid layer (Ω_2): $\nu(x) = \nu_1$ inside the cell and $\nu(x) = \nu_2$ in the lipid layer, with $\nu_1 \ll \nu_2$.

near the corners of the domain. The theoretical optimality of the asymptotic analysis based on the matching of the main singularities within Kondratiev theory [9] is confirmed by numerical computations. The paper is organized as follows. In Section 2, we introduce the model problem and the interface condition used in this paper. In Section 3, a rapid review of some consequences of Kondratiev theory [9] is presented. In Section 4, we recall the strategy of improving the convergence rates around corner singularities and derive an optimal choice of the transmission conditions near the corner. In the remainder of the paper, we give some practical examples and numerical experiments which confirm the optimality of such coefficients.

2. NEW INTERFACE CONDITIONS

Valid interface conditions in the vicinity of the corners are deduced from regular interfaces conditions (case without corners). We recall some results of the regular cases, and propose new interface conditions valid near the corner.

2.1. Case of a regular interface

We consider the reaction-diffusion problems:

$$\begin{cases} -\nabla \cdot (\nu(x)\nabla u) + \eta(x)u = f & \text{for } x \in \Omega \subset \mathbb{R}^2, \\ |u| < +\infty \text{ as } x \rightarrow \infty, \end{cases} \quad (2.1)$$

where f is the right-hand side, and the scalar diffusion coefficient $\nu(x)$ and $\eta(x)$ are piecewise constant

$$\nu(x) = \begin{cases} \nu_1 & \text{in } \Omega_1 \\ \nu_2 & \text{in } \Omega_2 \end{cases} \quad \eta(x) = \begin{cases} \eta_1 & \text{in } \Omega_1 \\ \eta_2 & \text{in } \Omega_2. \end{cases}$$

We consider here the model problem posed on the infinite plane $\Omega = \mathbb{R}^2$. It can be decomposed into two half-planes, $\Omega_1 = (-\infty, 0) \times \mathbb{R}$ and $\Omega_2 = (0, +\infty) \times \mathbb{R}$. The solution u must satisfy two conditions at the interface $x = 0$:

$$u(0^+, y) = u(0^-, y), \quad \text{and} \quad \nu_1 \frac{\partial u}{\partial x}(0^+, y) = \nu_2 \frac{\partial u}{\partial x}(0^-, y), \quad y \in \mathbb{R}.$$

These conditions are simply the continuity of u and of the flux. We wish to analyze the performance of the Schwarz iteration, and minimize the convergence factor over all frequencies relevant to the problem, see [5,10]: if (u_1^n, u_2^n) are known, the step $n + 1$ is determined by solving

$$\begin{cases} -\nu_1 \Delta u_1^{n+1} + \eta_1 u_1^{n+1} = f & \text{in } \Omega_1, \\ (\nu_1 \frac{\partial}{\partial n_1} + \mathcal{S}_2) u_1^{n+1}(0, y) = (-\nu_2 \frac{\partial}{\partial n_2} + \mathcal{S}_2) u_2^n(0, y), & y \in \mathbb{R} \\ |u_1^{n+1}| < \infty, \end{cases} \quad (2.2)$$

$$\begin{cases} -\nu_2 \Delta u_2^{n+1} + \eta_2 u_2^{n+1} = f & \text{in } \Omega_2, \\ (\nu_2 \frac{\partial}{\partial n_2} + \mathcal{S}_1) u_2^{n+1}(0, y) = (-\nu_1 \frac{\partial}{\partial n_1} + \mathcal{S}_1) u_1^n(0, y), & y \in \mathbb{R} \\ |u_2^{n+1}| < \infty, \end{cases} \quad (2.3)$$

where \mathcal{S}_j , $j = 1, 2$, are linear operators acting in the y direction only. By linearity, it will be sufficient to consider only the homogeneous case $f = 0$. Our simple model problem allows us to use a Fourier transform in the y variable, *i.e.*:

$$\hat{u}(x, k) = \int_{-\infty}^{+\infty} u(x, y) e^{-iyk} dy,$$

to analyze the convergence of the Schwarz method (2.2) and (2.3). A natural question is how to choose the transmission conditions in the Schwarz method to get fast convergence “in terms of iterations”. Good choices of the transmission conditions optimize the performance of the Schwarz iteration. The main idea is to fix a certain class of local transmission conditions and to optimize the convergence factor of the iteration over this class, for further details see [5]. To do this, we need to have an explicit expression for the convergence factor ρ , although it is hard to estimate in general. For the reaction-diffusion problems, the convergence can be fully analyzed, and a convergence factor $\rho(k)$ (as a function of the frequencies tangent to the interface) can be obtained using a Fourier transform. This strategy was first introduced in [7] for the advection-diffusion equation, where a certain subclass of second order conditions was optimized for non-overlapping subdomains. By requiring that the solution in each subdomain be bounded at infinity, and applying the transmission conditions that couple the two subdomains, we find the convergence factor

$$\rho(k) = \left| \frac{\sigma_2(k) - \nu_2 \sqrt{k^2 + c_2}}{\sigma_2(k) + \nu_1 \sqrt{k^2 + c_1}} \frac{\sigma_1(k) - \nu_1 \sqrt{k^2 + c_1}}{\sigma_1(k) + \nu_2 \sqrt{k^2 + c_2}} \right|,$$

where $c_i = \frac{\eta_i}{\nu_i}$ and $\sigma_j(k)$ are the Fourier symbols of the operators \mathcal{S}_j . Practically used and efficient interface conditions involve second order tangential derivatives,

$$\mathcal{S}_j = \nu_j \left(\beta - \frac{\partial}{\partial \tau} \left(\frac{\alpha}{2} \frac{\partial}{\partial \tau} \right) \right),$$

where $\frac{\partial}{\partial \tau}$ denotes the tangential derivative and α and β are constants. A simple computation gives

$$\sigma_j(k) = \nu_j \left(\beta + \frac{\alpha}{2} k^2 \right).$$

Let h be the characteristic mesh size of the numerical discretization. Assuming Ω is split into two half-planes and for a given bounded set of frequencies (k_1, k_2) in the tangential variable with $k_1 > 0$ and k_2 proportional to $\frac{1}{h}$, there is an optimal choice of (α, β) for the convergence of the domain decomposition process (2.2)–(2.3). By introducing the error $e_i^n(x, \tau) = u_i^n - u$ at step n and its Fourier transform $\widehat{e_i^n}(x, k)$ in the tangential variable, the optimized coefficients $\alpha_{\text{opt}} > 0$ and $\beta_{\text{opt}} > 0$ are determined according to [4] by the min-max problem

$$\min_{\alpha > 0, \beta \geq 0} \left(\max_{0 < k_1 \leq k \leq k_2} |\rho(k; \alpha, \beta)| \right), \quad (2.4)$$

where k_1 is a lower bound on the frequency range, k_2 is a maximal frequency which can be represented on a grid with grid spacing h (an estimate for this maximal frequency is $\frac{\pi}{h}$), and the convergence factor is

$$\rho(k; \alpha, \beta) = \left| \frac{\beta + \frac{\alpha}{2}k^2 - \sqrt{k^2 + c_2}}{\beta + \frac{\alpha}{2}k^2 + \frac{1}{\lambda}\sqrt{k^2 + c_1}} \quad \frac{\beta + \frac{\alpha}{2}k^2 - \sqrt{k^2 + c_1}}{\beta + \frac{\alpha}{2}k^2 + \lambda\sqrt{k^2 + c_2}} \right|,$$

where $\lambda = \frac{\nu_2}{\nu_1}$.

Theorem 2.1 (cf. [4]). *The min-max problem (2.4) has a unique solution given by:*

$$k^* = \sqrt{\frac{\pi}{\lambda + 1} \left(\lambda\sqrt{k_1^2 + c_1} + \sqrt{k_1^2 + c_2} \right) h^{-\frac{1}{2}}},$$

$$\beta_{\text{opt}} = \left[\frac{\pi}{4(\lambda + 1)^3} \left(\lambda\sqrt{k_1^2 + c_1} + \sqrt{k_1^2 + c_2} \right)^3 \right]^{\frac{1}{4}} h^{-\frac{1}{4}},$$

and

$$\alpha_{\text{opt}} = 2 \left[\frac{\lambda + 1}{4\pi^3 \left(\lambda\sqrt{k_1^2 + c_1} + \sqrt{k_1^2 + c_2} \right)} \right]^{\frac{1}{4}} h^{\frac{3}{4}}.$$

After this presentation of some results in the case of a regular interface, our goal now is to give the form of interface conditions available near the corner and their optimal parameters.

2.2. Interface conditions in the vicinity of the corner

The decomposition of a regular domain into non-overlapping subdomains can produce interior artificial corners on the interfaces. This makes artificial singularities appear in the solution of the subdomain problems. In order to have a good study of our problem one can consider a domain with only one interior corner. Here the full domain $\Omega = \mathbb{R}^2 = \mathbb{R}_+^* \times S^1 \cup \{O\}$ written in polar coordinates (r, θ) where the origin O corresponds to $r = 0$, will be decomposed into two non-overlapping sectorial subdomains $\bar{\Omega} = \bar{\Omega}_1 \cup \bar{\Omega}_2$, with $\Omega_1 = \mathbb{R}_+^* \times (\theta_-, \theta_+)$, $\Omega_2 = \mathbb{R}_+^* \times (\theta_+, \theta_- + 2\pi)$ and $\theta_+ - \theta_- \in (0, 2\pi)$. In the case of a singular domain, following the approach presented in [1,2] (see also the discussion in [11]), the interface condition of the regular interface must be modified in the vicinity of the corner. Indeed, one can show that asymptotically (as $r \rightarrow 0$) the interface conditions behave as Dirichlet interface conditions and do not transmit information well from one subdomain to its neighboring ones, for further details see [2]. This was considered in [11] as the explanation of a slow convergence of a domain decomposition algorithm around corners. One way to solve this problem is to force all the terms of the boundary interface operators to have the same homogeneity degree. Thus, a good candidate for the boundary conditions has the form $\pm\nu_i \frac{\partial}{r\partial\theta} + \tilde{\mathcal{S}}_j$ where

$$\tilde{\mathcal{S}}_j = \nu_j \left(\frac{\beta_{1,2}}{r} - \frac{\partial}{\partial r} \left(\frac{\alpha_{1,2}}{2} r \frac{\partial}{\partial r} \right) \right)$$

holds around the corner $r = 0$, with $\alpha_{1,2}$ and $\beta_{1,2}$ constant. Far from the corner, the interface boundary must keep the optimal form of the regular interface, for further details see [2]. In summary, we take

$$B_{i,j}(\pm\nu_i \frac{\partial}{r\partial\theta} u, u) = \pm\nu_i \frac{\partial}{r\partial\theta} u + \nu_j \tilde{\beta}_{1,2}(r) u - \nu_j \frac{\partial}{\partial r} \frac{\tilde{\alpha}_{1,2}(r)}{2} \frac{\partial}{\partial r} u, \quad (2.5)$$

$$\text{with } \tilde{\alpha}_{1,2}(r) = \begin{cases} \alpha_{1,2} r & \text{if } r \leq \frac{\alpha_{\text{opt}}}{\alpha_{1,2}}, \\ \alpha_{\text{opt}} & \text{if } r \geq \frac{\alpha_{\text{opt}}}{\alpha_{1,2}}, \end{cases} \quad \tilde{\beta}_{1,2}(r) = \begin{cases} \frac{\beta_{1,2}}{r} & \text{if } r \leq \frac{\beta_{1,2}}{\beta_{\text{opt}}}, \\ \beta_{\text{opt}} & \text{if } r \geq \frac{\beta_{1,2}}{\beta_{\text{opt}}}, \end{cases} \quad (2.6)$$

where $\alpha_{1,2} > 0$, $\beta_{1,2} \geq 0$ and the pair $(\alpha_{\text{opt}}, \beta_{\text{opt}})$ is given by Theorem 2.1.

In the next sections, we will see how to choose α_1, β_1 in (2.6) in order to reduce the corner singularities of u_1^n (the same can be done for u_2^n), which is a solution of

$$\begin{cases} -\nu_1 \frac{1}{r^2} \left((r\partial_r)^2 + \partial_\theta^2 \right) u_1^{n+1}(r, \theta) + \eta_1 u_1^{n+1}(r, \theta) = 0, \\ \left(-\nu_1 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) u_1^{n+1}(r, \theta_-) = \left(-\nu_2 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) u_2^n(r, \theta_- + 2\pi), \\ \left(\nu_1 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) u_1^{n+1}(r, \theta_+) = \left(\nu_2 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) u_2^n(r, \theta_+). \end{cases} \quad (2.7)$$

3. CORNER SINGULARITIES ANALYSIS

An important ingredient for the analysis of corner singularities is the Mellin transform (see [2] for further details) with respect to the radial variable, defined as

$$\hat{f}(z) = \mathcal{M}(f)(z) = \int_0^\infty r^{iz} f(r) \frac{dr}{r}.$$

Recall that

$$\mathcal{M}(ir \partial_r f)(z) = z \mathcal{M}(f)(z). \quad (3.1)$$

Then the asymptotic expansion of u , with $\text{supp } u \subset \{r \leq 1\}$:

$$u(r, \theta) = \sum_{k=1}^{\infty} \sum_{j=0}^{\mu_k-1} a_{k,j} r^{-iz_k} \ln^j(r) \varphi_{k,j}(\theta)$$

can be written in terms of $\mathcal{M}u$ which is meromorphic in some upper half-complex plane by noticing that

- z_k are the poles of $\mathcal{M}u$;
- μ_k are their corresponding multiplicity;
- $\varphi_{k,j}$ encode the angular variations;
- $a_{k,j} \in \mathbb{R}$.

When one solves the reaction-diffusion problems with Dirichlet boundary condition in some domain $\Omega = \{(r, \theta), 0 < r < 1, \theta_- < \theta < \theta_+\}$ for real values $\theta_\pm \in (0, 2\pi)$ and with a vanishing f around $\{r = 0\}$, the main term of the asymptotic expansion is obtained by looking for the z 's for which the angular boundary value problem

$$\begin{cases} (\partial_\theta(\nu \partial_\theta) - \nu z^2) \hat{e}(z, \theta) = 0, \\ \hat{e}(z, \theta_-) = 0, \\ \hat{e}(z, \theta_+) = 0, \end{cases} \quad (3.2)$$

admits a non-trivial solution. The z^2 are actually the poles of the meromorphic resolvent attached to the asymptotic as $r \rightarrow 0$ angular problem according to Kondratiev theory, see [9] for further details.

3.1. Expansion of a solution to the problem in Ω

The final aim of our work is to improve the convergence of domain decomposition methods in the neighborhood of corners. The relevant analysis has to be done in a neighborhood of $r = 0$. It is sufficient to consider truncated solutions $\psi(r)u$, with $\psi \in \mathcal{C}_0^\infty(\mathbb{R}_+)$, $\text{supp } \psi \subset \{r \leq 1\}$ and $\psi \equiv 1$ in a neighborhood of $\{r = 0\}$. One can even consider directly the the situation $u = \psi(r)u$. The natural singularities exponent and the angular functions associated with the boundary value problem (1.1) are given by the next proposition.

Proposition 3.1. *Let $\Theta = \theta_+ - \theta_- - \pi$, and $\kappa = \left(\frac{\nu_2 - \nu_1}{\nu_2 + \nu_1}\right)^2$. The complex numbers z for which (1.1) admits a non-trivial solution are given by $z = it$, $t \in \mathbb{R}$ with*

$$\sin^2(\pi t) = \kappa \sin^2(\Theta t). \quad (3.3)$$

Proof. We note that $e = \psi e$, where ψ is a smooth function with compact support and e is the solution of the homogeneous equation associated to the principal part of the operator. Considering the principal part as $r \rightarrow 0$ of the problem (1.1) and applying the Mellin transform, we are led to consider the equation:

$$(\partial_\theta(\nu \partial_\theta) - \nu z^2) \hat{e}(z, \theta) = 0.$$

Here $\hat{e}(z, \cdot)$ is an eigenfunction of the operator $K(\theta) = -\frac{\partial}{\partial \theta} \left(\nu \frac{\partial}{\partial \theta} \right)$, defined on

$$\mathcal{D}(\theta) = \left\{ u \in H^1(\Omega), \left[\nu \frac{\partial u}{\partial \theta} \right]_{|\partial\Omega_1 \cap \partial\Omega_2} = 0 \right\}$$

for the eigenvalue $-\nu z^2$. Moreover, $K(\theta)$ is a self-adjoint positive operator and thus $z^2 \leq 0$ and $z = it$ with $t > 0$. As $\nu(x)$ is a piecewise constant coefficient, we solve the problem in each subdomain. A simple calculation gives

$$A_i \cos(t\theta) + B_i \sin(t\theta) \text{ in } \Omega_i.$$

Moreover, we impose that on the interface $\{\theta = \theta_\pm\}$ we have

$$\begin{aligned} \hat{e}(t, \theta) \Big|_{\Omega_1, \theta_+} &= \hat{e}(t, \theta) \Big|_{\Omega_2, \theta_+} \\ \hat{e}(t, \theta) \Big|_{\Omega_1, \theta_-} &= \hat{e}(t, \theta) \Big|_{\Omega_2, \theta_- + 2\pi} \\ \nu_1 \frac{\partial}{\partial \theta} \hat{e}(t, \theta) \Big|_{\Omega_1, \theta_+} &= \nu_2 \frac{\partial}{\partial \theta} \hat{e}(t, \theta) \Big|_{\Omega_2, \theta_+} \\ \nu_1 \frac{\partial}{\partial \theta} \hat{e}(t, \theta) \Big|_{\Omega_1, \theta_-} &= \nu_2 \frac{\partial}{\partial \theta} \hat{e}(t, \theta) \Big|_{\Omega_2, \theta_- + 2\pi}. \end{aligned} \tag{3.4}$$

This leads to

$$M_{\nu_1, \nu_2}(t) \begin{pmatrix} A_1 \\ B_1 \\ A_2 \\ B_2 \end{pmatrix} = 0_{\mathbb{R}^4},$$

where

$$M_{\nu_1, \nu_2}(z) = \begin{pmatrix} \cos(t\theta_+) & \sin(t\theta_+) & -\cos(t\theta_+) & -\sin(t\theta_+) \\ \cos(t\theta_-) & \sin(t\theta_-) & -\cos(t(\theta_- + 2\pi)) & -\sin(t(\theta_- + 2\pi)) \\ -\nu_1 \sin(t\theta_+) & \nu_1 \cos(t\theta_+) & \nu_2 \sin(t\theta_+) & -\nu_2 \cos(t\theta_+) \\ -\nu_1 \sin(t\theta_-) & \nu_1 \cos(t\theta_-) & \nu_2 \sin(t(\theta_- + 2\pi)) & -\nu_2 \cos(t(\theta_- + 2\pi)) \end{pmatrix}.$$

The poles are solutions of $\det M_{\nu_1, \nu_2}(t) = 0$. A straightforward computation then gives

$$\frac{(\nu_1 + \nu_2)^2}{4\nu_1\nu_2} \cos(2\pi t) - \frac{(\nu_1 - \nu_2)^2}{4\nu_1\nu_2} \cos(2t(\theta_+ - \theta_- - \pi)) = 1.$$

Therefore, the poles are solutions of

$$\sin^2(\pi t) = \kappa \sin^2(t(\theta_+ - \theta_- - \pi)), \tag{3.5}$$

where $\kappa = \left(\frac{\nu_2 - \nu_1}{\nu_2 + \nu_1} \right)^2$. □

Then, the first term in the asymptotic expansion of u is given by

$$e(r, \theta) = A_0 + r^{\tau_1} \begin{cases} A_1 \cos(\tau_1 \theta) + B_1 \sin(\tau_1 \theta) & \text{in } \Omega_1 \\ A_2 \cos(\tau_1 \theta) + B_2 \sin(\tau_1 \theta) & \text{in } \Omega_2 \end{cases} + o(r^{\tau_1}),$$

where τ_1 denotes the first positive solution of (3.3).

3.2. Subproblem in Ω_1

We focus on the subdomain Ω_1 , the treatment of Ω_2 being similar. The boundary problem with the selected interface conditions solved with the error $e_1^{n+1} = u_1^{n+1} - u$ reads

$$\begin{cases} -\nu_1 \frac{1}{r^2} \left((r\partial_r)^2 + \partial_\theta^2 \right) e_1^{n+1}(r, \theta) + \eta_1 e_1^{n+1}(r, \theta) = 0, \\ \left(-\nu_1 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) e_1^{n+1}(r, \theta_-) = \left(-\nu_2 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) e_2^n(r, \theta_- + 2\pi), \\ \left(\nu_1 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) e_1^{n+1}(r, \theta_+) = \left(\nu_2 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) e_2^n(r, \theta_+), \end{cases} \quad (3.6)$$

where

$$\tilde{\mathcal{S}}_2 = \nu_2 \left(\frac{\beta_1}{r} - \frac{\partial}{\partial r} \left(\frac{\alpha_1}{2} r \frac{\partial}{\partial r} \right) \right).$$

The case $\beta \neq 0$ is not permitted in interior corners of $\Omega = \mathbb{R}^2$, or more generally when the general solution of the complete problem does not vanish at $r = 0$ (for further details see [2]). The main singularities associated with this problem are derived following Kondratiev theory [9]. By considering the principal part as $r \rightarrow 0$ and by applying the Mellin transform, leads to the system

$$\begin{cases} (\partial_\theta^2 - z^2) \widehat{e}_1^{n+1}(z, \theta) = 0, \\ (\partial_\theta - \lambda \frac{\alpha_1}{2} z^2) \widehat{e}_1^{n+1}(z, \theta_-) = \widehat{g}_-^n(z), \\ (\partial_\theta + \lambda \frac{\alpha_1}{2} z^2) \widehat{e}_1^{n+1}(z, \theta_+) = \widehat{g}_+^n(z), \end{cases} \quad (3.7)$$

where

$$\widehat{g}_+^n(z) = \lambda \left(\partial_\theta + \frac{\alpha_1}{2} z^2 \right) \widehat{e}_2^n(z, \theta_+), \quad \widehat{g}_-^n(z) = \lambda \left(\partial_\theta - \frac{\alpha_1}{2} z^2 \right) \widehat{e}_2^n(z, \theta_- + 2\pi), \quad \lambda = \frac{\nu_2}{\nu_1},$$

and whose solution is

$$\begin{aligned} \widehat{e}_1^{n+1} &= a(z) e^{z(\theta - \theta_-)} + b(z) e^{-z(\theta - \theta_+)} \\ \begin{pmatrix} a(z) \\ b(z) \end{pmatrix} &= \frac{1}{z} \mathcal{R}(z) \begin{pmatrix} \widehat{g}_+^n(z) \\ \widehat{g}_-^n(z) \end{pmatrix} \\ \text{with } \mathcal{R}(z) &= \begin{pmatrix} (1 + \lambda \frac{\alpha_1}{2} z) e^{z(\theta_+ - \theta_-)} & -1 + \lambda \frac{\alpha_1}{2} z \\ 1 - \lambda \frac{\alpha_1}{2} z & -(1 + \lambda \frac{\alpha_1}{2} z) e^{z(\theta_+ - \theta_-)} \end{pmatrix}^{-1}. \end{aligned}$$

Proposition 3.2. *The poles with a positive imaginary part of the factor $\mathcal{R}(z)$ are $z = it$, with*

$$\tan \left(\frac{\pi x t}{2} \right) = \frac{2}{\lambda \alpha_1 t} \quad (3.8)$$

$$\tan \left(\frac{\pi x t}{2} \right) = -\frac{\lambda \alpha_1}{2} t, \quad (3.9)$$

with $x = \frac{\theta_+ - \theta_-}{\pi}$, whose positive solutions are denoted by t_k , $k \in \mathbb{N}^*$, in the increasing order.

Proof. See [2]. □

It follows immediately from the positiveness of $\lambda = \frac{\nu_2}{\nu_1}$, x and α_1 that the first pole it_1 is associated with the equation

$$\tan \left(\frac{\pi x t}{2} \right) = \frac{2}{\lambda \alpha_1 t}.$$

In the next section, we derive an optimal parameter α_1 for the subproblem in Ω_1 (if it is possible) such that the first pole it_1 will be canceled.

4. THEORETICAL CHOICE OF THE PARAMETER α_1

We give here a short summary of the strategy of optimization – for further details refer to [2]. Expecting that better matching yields faster convergence, our strategy to determine the “best parameter” (α_i) is the following: assuming that at step n the error functions $e_i^n = u_i^n - u$, $i = 1, 2$, have the asymptotic type of the problem on the full domain Ω , the error functions e_i^{n+1} should keep this asymptotic type up to some large enough order as $r \rightarrow 0$. (*That is, domain decomposition is used for the solution procedure, and for the corresponding iteration we try to define the transmission conditions in such a way that additional artificial singularities in the corner either are suppressed or are at most of the same order as the singularity of the original problem.*) The analysis focuses on the first artificial pole, which is the one with the smallest imaginary part. The corresponding residual depends on the right-hand side in (2.7), which for the first order is given by the asymptotic type of the full domain problem. The question now becomes whether it is possible to choose the parameter α_i in Ω_i , $i = 1, 2$, so that if the data involved in the right-hand side of (2.7) has the right asymptotic type, then the first artificial pole is canceled by a vanishing residue. The computation will show that such a choice of the parameter is not always possible, and in the general case we have to choose between two strategies in each subdomain Ω_i , $i = 1, 2$:

- (1) Check if it is possible to cancel the first artificial pole according to the previous process;
- (2) If the first approach has no solution, choose the parameter α_i , $i = 1, 2$, in such a way that the first artificial pole has the largest possible imaginary part.

Keep in mind that $\beta_i = 0$ is necessary² because the solution u , has in general, a nonzero value at $r = 0$. Only the coefficients α_i can be used. In the subdomain Ω_1 and for a general right-hand side in (2.7), the first artificial term in the asymptotic expansion of e_1^{n+1} appears with the factor r^{t_1} , with t_1 defined in Proposition 3.2. The first (and most efficient) approach assumes that at step n the error has the natural asymptotic type associated with the global problem:

$$e_2^n(r, \theta) = A_0 + r^{\tau_1} (A_2 \cos(\tau_1 \theta) + B_2 \sin(\tau_1 \theta)) + o(r^{\tau_1}),$$

where τ_1 denotes the first positive solution of (3.3). With an additional truncation in $\{r \leq R\}$ we set the following as in the domain decomposition algorithm

$$\begin{aligned} g_+^n(r) &= 1_{\{r \leq R\}} \lambda \left(\partial_\theta - \frac{\alpha_1}{2} (r \partial_r)^2 \right) e_2^n(r, \theta_+), \\ g_-^n(r) &= 1_{\{r \leq R\}} \lambda \left(\partial_\theta + \frac{\alpha_1}{2} (r \partial_r)^2 \right) e_2^n(r, \theta_- + 2\pi), \end{aligned}$$

where $R \in \mathbb{R}_+^*$. After working with the first order expansion of the global problem, neglecting the $o(r^{\tau_1})$ remainder and taking the Mellin transform, this provides

$$\begin{aligned} \widehat{g_+^n}(z) &= \frac{R^{\tau_1 + iz}}{\tau_1 + iz} \lambda \tau_1 \left\{ A_2 \left(-\sin(\tau_1 \theta_+) - \tau_1 \frac{\alpha_1}{2} \cos(\tau_1 \theta_+) \right) + B_2 \left(\cos(\tau_1 \theta_+) - \tau_1 \frac{\alpha_1}{2} \sin(\tau_1 \theta_+) \right) \right\}, \\ \widehat{g_-^n}(z) &= \frac{R^{\tau_1 + iz}}{\tau_1 + iz} \lambda \tau_1 \left\{ A_2 \left(-\sin(\tau_1 (\theta_- + 2\pi)) + \tau_1 \frac{\alpha_1}{2} \cos(\tau_1 (\theta_- + 2\pi)) \right) \right. \\ &\quad \left. + B_2 \left(\cos(\tau_1 (\theta_- + 2\pi)) + \tau_1 \frac{\alpha_1}{2} \sin(\tau_1 (\theta_- + 2\pi)) \right) \right\}. \end{aligned}$$

We note that the boundary conditions do not contain a constant term $(\partial_\theta - \frac{\alpha_1}{2} (r \partial_r)^2)$ and therefore g_\pm^n do not depend on the first term (A_0) in the expansion of e_2^n .

²Practically, the case $\beta_i = 0$ is implemented by keeping a constant coefficient $\tilde{\beta}(r) = \beta_{\text{opt}}$ along the whole interface.

Our goal is to see whether there exists α_1 such that

$$\mathcal{R}(z) \left(\begin{array}{c} \widehat{g}_+^n(z) \\ \widehat{g}_-^n(z) \end{array} \right) \text{ does not have any more pole on } it_1 \text{ (} t_1 > 0 \text{)}.$$

According to [1,2], here the cancellation of the first artificial pole it_1 is reduced to the simple condition

$$\widehat{g}_+^n(it_1) = -\widehat{g}_-^n(it_1). \quad (4.1)$$

Proposition 4.1. *The equation (4.1) gives*

$$\alpha_1 = \frac{2}{\tau_1} \frac{1}{\tan\left(\frac{\theta_+ - \theta_- - 2\pi}{2} \tau_1\right)} \quad (4.2)$$

for $\frac{\theta_+ - \theta_-}{\pi} \in (2 - \frac{2}{\tau_1}, 2 - \frac{1}{\tau_1})$.

Proof. Equation (4.1) does not depend on the truncation parameter R and reads simply

$$\alpha_1 = \alpha_1 = \frac{2}{\tau_1} \frac{1}{\tan\left(\frac{\theta_+ - \theta_- - 2\pi}{2} \tau_1\right)}.$$

We recall that $0 < \theta_+ - \theta_- < 2\pi$, which implies

$$-\pi < \frac{\theta_+ - \theta_- - 2\pi}{2} \tau_1 < 0.$$

If $\frac{\theta_+ - \theta_- - 2\pi}{2} \tau_1 \in (-\pi, -\frac{\pi}{2})$, then the parameter α_1 is positive and this yields the result. \square

Remark 4.2. If $\nu_1 = \nu_2$, condition (4.2) becomes

$$\alpha_1 = \frac{2}{\tan\left(\frac{\theta_+ - \theta_-}{2}\right)} \text{ for } \frac{\theta_+ - \theta_-}{\pi} \in (0, 1)$$

and thus, we recover the optimized coefficients of the Laplace operator in the same domain [1–3].

5. EXAMPLES

The characteristic equation (3.3) cannot be solved explicitly. Therefore, in this section we consider the case $\theta_+ - \theta_- = \frac{\pi}{2}$. In this case we can explicitly compute the first pole

$$\tau_1 = \frac{1}{\pi} \arccos\left(-\frac{\nu_1^2 + \nu_2^2 + 6\nu_1\nu_2}{2(\nu_1 + \nu_2)^2}\right).$$

Moreover, $\tau_1 \in (\frac{2}{3}, 1)$. Then (3.3) yields

$$\alpha_1 = -\frac{2}{\tau_1} \frac{1}{\tan\left(\frac{3\pi}{4} \tau_1\right)} > 0.$$

In the case when $\theta_+ - \theta_- = \frac{3\pi}{2}$, the first pole is the same as the case where $\theta_+ - \theta_- = \frac{\pi}{2}$. But, in this case (3.3) gives

$$\alpha_1 = -\frac{2}{\tau_1} \frac{1}{\tan\left(\frac{\pi}{4} \tau_1\right)} < 0.$$

Therefore, for a given $\theta_+ - \theta_-$ we cannot always cancel the first artificial pole, so the two strategies of optimization can be used for our problem. For instance, when the domain Ω is decomposed into one cell Ω_1 and a lipid layer Ω_2 , correspond to the case of Figure 1, we see that the first strategy is used only in the cell and the second strategy in Ω_2 . Up to now, we keep in mind that the first approach depending on the angle of the subdomain Ω_i , does not admit a solution in all cases. The second approach will also be tested when necessary.

If we consider the case where $\nu_1 = 1$ and $\nu_2 \gg \nu_1$, then the first pole is given by

$$\tau_1 = \frac{1}{\pi} \arccos \left(- \frac{1 + \nu_2^2 + 6\nu_2}{2(1 + \nu_2)^2} \right).$$

According to the formula for τ_1 , one sees that τ_1 is monotonically decreasing with ν_2 (we consider ν_2 as parameter) to the value $\frac{2}{3}$. Therefore, the solution of the interface problem belongs to $H^{1+\frac{2}{3}}(\Omega)$ independently of the jump discontinuity of the diffusion coefficient. We recall that the Sobolev space $H^s(\Omega)$, $s > 0$, $s \notin \mathbb{N}$, is defined as the space of all distributions with finite norm:

$$\|v\|_{H^s(\Omega)}^2 = \|v\|_{H^m(\Omega)}^2 + \sum_{|\zeta|=m} \int_{\Omega} \int_{\Omega} \frac{|D^{\zeta}v(x) - D^{\zeta}v(y)|^2}{|x - y|^{2+2\sigma}} dx dy$$

where $s = m + \sigma$, $m \in \mathbb{N}$, $\sigma \in (0, 1)$ and D^{ζ} denotes the derivatives with respect to the multi-index $\zeta = (\zeta_1, \zeta_2)$ (see [6] for more details).

6. DISCRETE PROBLEM

Owing to a reformulation of the algorithm the computation of the normal derivative involved in these interface conditions is avoided. For the sake of simplicity we still consider a case with two subdomains, but this procedure can be adapted to any general decomposition with more than two subdomains. We restrict our attention to the additive Schwarz iteration

$$\begin{cases} -\nu_1 \Delta u_1^{n+1} + \eta_1 u_1^{n+1} = f, \\ \left(-\nu_1 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_2 \right) u_1^{n+1}(r, \theta_-) = \left(-\nu_2 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_2 \right) u_2^n(r, \theta_-), \\ \left(\nu_1 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_2 \right) u_1^{n+1}(r, \theta_+) = \left(\nu_2 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_2 \right) u_2^n(r, \theta_+), \end{cases} \quad (6.1)$$

$$\begin{cases} -\nu_2 \Delta u_2^{n+1} + \eta_2 u_2^{n+1} = f, \\ \left(\nu_2 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_1 \right) u_2^{n+1}(r, \theta_-) = \left(\nu_1 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_1 \right) u_1^n(r, \theta_-), \\ \left(-\nu_2 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_1 \right) u_2^{n+1}(r, \theta_+) = \left(-\nu_1 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_1 \right) u_1^n(r, \theta_+). \end{cases} \quad (6.2)$$

A direct discretization would require the computation of the normal derivatives along the interfaces $\{\theta = \theta_{\pm}\}$ in order to evaluate the right hand sides in the transmission conditions of (6.2)–(6.1). This can be avoided by introducing four new variables,

$$\begin{aligned} \lambda_{(1, \theta_-)}^n &= \left(-\nu_2 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_2 \right) u_2^n(\cdot, \theta_-), \\ \lambda_{(1, \theta_+)}^n &= \left(\nu_2 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_2 \right) u_2^n(\cdot, \theta_+), \\ \lambda_{(2, \theta_-)}^n &= \left(\nu_1 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_1 \right) u_1^n(\cdot, \theta_-), \\ \lambda_{(2, \theta_+)}^n &= \left(-\nu_1 \frac{1}{r} \partial_{\theta} + \tilde{\mathcal{S}}_1 \right) u_1^n(\cdot, \theta_+). \end{aligned}$$

The algorithm then becomes

$$\left\{ \begin{array}{l} -\nu_1 \Delta u_1^{n+1} + \eta_1 u_1^{n+1} = f, \\ \left(-\nu_1 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) u_1^{n+1}(r, \theta_-) = \lambda_{(1, \theta_-)}^n(r), \\ \left(\nu_1 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_2 \right) u_1^{n+1}(r, \theta_+) = \lambda_{(1, \theta_+)}^n(r), \\ \\ -\nu_2 \Delta u_2^{n+1} + \eta_2 u_2^{n+1} = f, \\ \left(\nu_2 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_1 \right) u_2^{n+1}(r, \theta_-) = \lambda_{(2, \theta_-)}^n(r), \\ \left(-\nu_2 \frac{1}{r} \partial_\theta + \tilde{\mathcal{S}}_1 \right) u_2^{n+1}(r, \theta_+) = \lambda_{(2, \theta_+)}^n(r), \end{array} \right.$$

and

$$\begin{aligned} \lambda_{(1, \theta_-)}^{n+1} &= -\lambda_{(2, \theta_-)}^n + \left(\nu_2 \tilde{\beta}_1(r) + \nu_1 \tilde{\beta}_2(r) - \partial_r \left(\frac{[\nu_2 \tilde{\alpha}_1(r) + \nu_1 \tilde{\alpha}_2(r)]}{2} \partial_r \right) \right) u_2^n(\cdot, \theta_-), \\ \lambda_{(2, \theta_-)}^{n+1} &= -\lambda_{(1, \theta_-)}^n + \left(\nu_2 \tilde{\beta}_1(r) + \nu_1 \tilde{\beta}_2(r) - \partial_r \left(\frac{[\nu_2 \tilde{\alpha}_1(r) + \nu_1 \tilde{\alpha}_2(r)]}{2} \partial_r \right) \right) u_1^n(r, \theta_-), \\ \lambda_{(1, \theta_+)}^{n+1} &= -\lambda_{(2, \theta_+)}^n + \left(\nu_2 \tilde{\beta}_1(r) + \nu_1 \tilde{\beta}_2(r) - \partial_r \left(\frac{[\nu_2 \tilde{\alpha}_1(r) + \nu_1 \tilde{\alpha}_2(r)]}{2} \partial_r \right) \right) u_2^n(\cdot, \theta_+), \\ \lambda_{(2, \theta_+)}^{n+1} &= -\lambda_{(1, \theta_+)}^n + \left(\nu_2 \tilde{\beta}_1(r) + \nu_1 \tilde{\beta}_2(r) - \partial_r \left(\frac{[\nu_2 \tilde{\alpha}_1(r) + \nu_1 \tilde{\alpha}_2(r)]}{2} \partial_r \right) \right) u_1^n(\cdot, \theta_+). \end{aligned} \quad (6.3)$$

The variational formulation of the problem for each subdomain with interface conditions (2.5) is given by

$$\begin{aligned} \int_{\Omega_i} \eta_i u_i^{n+1} v_i + \int_{\Omega_i} \nu_i \nabla u_i^{n+1} \nabla v_i + \int_0^\infty \nu_j \tilde{\beta}_i(r) (u_i^{n+1} v_i)(r, \theta_\pm) + \int_0^\infty \frac{\nu_j \tilde{\alpha}_i(r)}{2} (\partial_r u_i^{n+1} \partial_r v_i)(r, \theta_\pm) \\ = \int_{\Omega_i} f v_i + \int_0^\infty \lambda_{(i, \theta_\pm)}^n v_i(r, \theta_\pm). \end{aligned}$$

This leads to a matrix form of the algorithm:

$$\begin{aligned} \widetilde{\mathcal{K}}_1 u_1^{n+1} &= f + B_1^T \lambda_1^n, \\ \widetilde{\mathcal{K}}_2 u_2^{n+1} &= f + B_2^T \lambda_2^n, \\ \mathcal{M}_\Gamma \lambda_1^{n+1} &= -\mathcal{M}_\Gamma \lambda_2^n + (\mathcal{M}_{\tilde{\beta}_1, \Gamma} + \mathcal{M}_{\tilde{\beta}_2, \Gamma} + \mathcal{K}_{\tilde{\alpha}_1, \Gamma} + \mathcal{K}_{\tilde{\alpha}_2, \Gamma}) B_2 u_2^{n+1}, \\ \mathcal{M}_\Gamma \lambda_2^{n+1} &= -\mathcal{M}_\Gamma \lambda_1^n + (\mathcal{M}_{\tilde{\beta}_1, \Gamma} + \mathcal{M}_{\tilde{\beta}_2, \Gamma} + \mathcal{K}_{\tilde{\alpha}_1, \Gamma} + \mathcal{K}_{\tilde{\alpha}_2, \Gamma}) B_1 u_1^{n+1}, \end{aligned} \quad (6.4)$$

where $\lambda_1, \lambda_2, u_1$ and u_2 denote the degrees of freedom of the finite element functions approaching the solution of the continuous problem, with the same names. The matrices B_1 and B_2 are the restriction operators (whose entries are one or zero) corresponding to trace operators of the domains Ω_1 and Ω_2 along the interface between the two subdomains. The matrices $\widetilde{\mathcal{K}}_1$ and $\widetilde{\mathcal{K}}_2$ arise from the discretization of the reaction-diffusion subproblems with the interface conditions (2.5)

$$\widetilde{\mathcal{K}}_j = \eta_j \mathcal{M}_j + \mathcal{K}_j + \nu_i B_j^T (\mathcal{M}_{\tilde{\beta}_j, \Gamma} + \mathcal{K}_{\tilde{\alpha}_j, \Gamma}) B_j, \quad \forall i, j = 1, 2, i \neq j. \quad (6.5)$$

Here \mathcal{K}_1 and \mathcal{K}_2 are the subdomain stiffness matrices, \mathcal{M}_1 and \mathcal{M}_2 are the subdomain mass matrices, \mathcal{M}_Γ and $\mathcal{M}_{\tilde{\beta}_j,\Gamma}$ are the interface mass matrices, and $\mathcal{K}_{\tilde{\alpha}_j,\Gamma}$ is the interface stiffness matrix,

$$\begin{aligned} (\mathcal{M}_\Gamma)_{ij} &= \int_0^\infty (\phi_i \phi_j)(r, \theta_-) \, dr, \\ (\mathcal{M}_{\tilde{\beta}_k,\Gamma})_{ij} &= \int_0^\infty \tilde{\beta}_k(r) (\phi_i \phi_j)(r, \theta_-) \, dr, \\ (\mathcal{K}_{\tilde{\alpha}_k,\Gamma})_{ij} &= \int_0^\infty \frac{\tilde{\alpha}_k(r)}{2} (\partial_r \phi_i \partial_r \phi_j)(r, \theta_-) \, dr. \end{aligned}$$

The functions ϕ_i and ϕ_j are the basis functions associated with the degrees of freedom i and j along the interface $\{\theta = \theta_-\}$.

7. NUMERICAL RESULTS

The numerical computations with the FreeFem++³ software consist in introducing the problem to be solved in each subdomain with its weak formulation. In the weak formulation, the tangential derivative involved in the boundary operator is implemented in FreeFem++ using the normal vector. In the numerical results we discretize all variational forms by P1-Lagrange finite elements. The effect of singularities associated with corners on domain decomposition methods is transparent when the discretization is fine enough. In order to show such effects without excessively increasing the numerical cost, a refinement of the mesh around the corner is considered. When the domain Ω is decomposed into two subdomains, one of them must be nonconvex. Assume $x(\Omega_1) = \frac{\theta_+ - \theta_-}{\pi} < 1$ and $x(\Omega_2) = \frac{\theta_- + 2\pi - \theta_+}{\pi} > 1$. The first strategy can be applied in Ω_1 with the optimal choice given by (4.2), while choosing the coefficient α_2 to be zero or very small in Ω_2 pushes the first artificial singularity as far as possible (second strategy). With this choice, the expansion of the artificial singularities around $r = 0$ has the order $O(r^{\min(t_2(\Omega_1), t_1(\Omega_2))})$. In our comparison of numerical methods, we shall use the terminology:

1. **ICCC** for the interface conditions with constant coefficients $(\alpha_{\text{opt}}, \beta_{\text{opt}})$ up to the corner.
2. **OCC** for the new interface conditions with optimized coefficients at the corner $(\alpha_{1,2}, \beta_{1,2})$.

The simple domain which will be considered in our computation is a disc of radius one, centered at the origin and we take a Dirichlet boundary condition $u = 0$ on $\partial\Omega$. This global domain is divided into two subdomains Ω_1 is a quarter of a disc and $\Omega_2 = \Omega \setminus \Omega_1$, see Figure 2.

The right-hand side f is taken constant and equal to 1 in the whole domain Ω . We are interesting to the corner singularities, writing our problem in polar coordinates and taking the principal part (Kondratiev theory) the two parameters η_1 and η_2 are suppressed when $r \rightarrow 0$, so in the algorithm we take $\eta_1 = \eta_2 = 1$. The convergence will be tested, and the logarithmic convergence curve will be plotted with the norm

$$|e|_1 = \left(\int_\Omega |\nabla e(x)|^2 dx \right)^{1/2}.$$

A comparison of the L^∞ -norm

$$\|e\|_{L^\infty(\Omega)}$$

of the error $|e_1(x)|$ will be presented for **OCC** and **ICCC**. Practically, the error function e^n at step n is computed as $u^N - u^n$ where u^n is the result after n iterations of the domain decomposition algorithm and N is large enough so that u^N is much closer to the (discrete) solution u^∞ than the numerical tolerance $\varepsilon = 10^{-12}$. Moreover, **OCC** interface conditions are used to get u^N . The u^N used to compute the error and the solution obtained with a monolithic discretization of the disc are the same. Our stopping criterium is not based

on the residual norm but on maximum norm of the difference between the discrete solution and its approximation by the iterative algorithm. Thus, there is no bias when we compare interface conditions. We will show by a series of numerical results that the relation (4.2) is optimal, and we limit our study to the geometrical configuration with only one interior corner, corresponding to the case of a circular domain decomposed into two subdomains. Here the disc is decomposed into two sectors with angles $\frac{\pi}{2}$ and $\frac{3\pi}{2}$. In the nonconvex subdomain Ω_2 with angle $\frac{3\pi}{2}$, the choice of $\alpha_2 = 0$ is done by taking $\tilde{\alpha}_2(r)$ proportional to r^2 on five elements of the grid close to the corner.

In the convex subdomain Ω_1 with angle $\frac{\pi}{2}$, we take $\alpha_1 = -\frac{2}{\tau_1} \frac{1}{\tan(\frac{3\pi}{4}\tau_1)}$, and we checked that the matching parameter ($\frac{\alpha_{\text{opt}}}{\alpha_{1,2}}$) in (2.6) is larger than four times the mesh size h of the refined mesh. We recall that the case $\nu_1 = \nu_2$ was presented numerically in Section 4.3 of [3]. Here we limit our study to the case $\nu_1 \neq \nu_2$. We use a uniform grid everywhere except at the corner $r = 0$. The domain decomposition algorithm is tested with various ratios $\frac{\nu_2}{\nu_1}$ in order to check that (4.2) is optimal (see Tab. 1). We recall that the shorthand **OCC** for the optimal parameter α_1 will be compared with the **ICCC** case (constant coefficients along the interface). If we take $\frac{\nu_2}{\nu_1} = 2$, case where $\nu_1 = 1$ and $\nu_2 = 2$, then with **ICCC**, 22 iterations are necessary in order to reach $|e_1^n|_1 \leq 10^{-6}$ instead of 12 with **OCC**. The plot of $\log_{10} |e_1^n|_1$ with respect to n (see Fig. 3) shows the improvement brought by **OCC**. Table 2 gives the L^∞ -norm of the error $|e_1(x)|$ with respect to n and shows the improvement given by **OCC**. The comparison is made between the speed at which the iterates approach an iterate of the **OCC** algorithm. This is particularly visible from Table 2: the errors associated to the two interface conditions are comparable for the first 6–7 iterations, then the **OCC** conditions outperform the **ICCC** ones.

In [4], using optimized second order conditions, a convergence factor of the form $1 - O(h^{\frac{1}{4}})$ is obtained, and the numerical experiment therein show that the convergence improves as the jump in the coefficient increases. The same property holds for optimized two-sided Robin conditions, and in that case we would gain the additional

advantage that the convergence is independent of the mesh size (see [4]); however for the analysis near the corners, it is more convenient to use second order conditions.

8. CONCLUSION

All the numerical experiments show that the implementation of **OCC** method improves the behavior of the error in the domain decomposition algorithms. The optimal coefficients for the corresponding transmission conditions are characterized in order to reduce the singularity in the error term. Considering the results obtained in this paper, we plan in the future to tackle the following open questions:

- The numerical results show the robustness of the algorithm with respect to the jumps in the coefficients, but its convergence is still an open problem.
- What happens if the pole of the resolvent is of higher order?
- A good application of our methods in such situations can be observed in two-dimensional domains with more than three subdomains sharing an interior point.
- Extension of our results to the three-dimensional case.
