THE SPLITTING IN POTENTIAL CRANK–NICOLSON SCHEME WITH DISCRETE TRANSPARENT BOUNDARY CONDITIONS FOR THE SCHRÖDINGER EQUATION ON A SEMI-INFINITE STRIP

BERNARD DUCOMET¹, ALEXANDER ZLOTNIK² AND ILYA ZLOTNIK³

Abstract. We consider an initial-boundary value problem for a generalized 2D time-dependent Schrödinger equation (with variable coefficients) on a semi-infinite strip. For the Crank–Nicolson-type finite-difference scheme with approximate or discrete transparent boundary conditions (TBCs), the Strang-type splitting with respect to the potential is applied. For the resulting method, the unconditional uniform in time $L^2$-stability is proved. Due to the splitting, an effective direct algorithm using FFT is developed now to implement the method with the discrete TBC for general potential. Numerical results on the tunnel effect for rectangular barriers are included together with the detailed practical error analysis confirming nice properties of the method.

1. Introduction

The multidimensional time-dependent Schrödinger equation describes most of microscopic phenomena in non-relativistic quantum mechanics, atomic and nuclear physics and it also appears more generally in wave physics and nanotechnologies. Due to the physical framework (quantum mechanics) the corresponding initial value problem must be solved in unbounded space domains however, due to computational constraints, it is necessary to restrict the analysis to a bounded region which implies to solve the delicate problem of prescribing suitable boundary conditions.

In this work an additional complication is that we consider a generalized 2D time-dependent Schrödinger equation (GSE) with variable coefficients (when the Laplace operator is replaced by an operator of “Laplace–Beltrami” type [17, 21, 23]) on a semi-infinite strip. This model appears in nuclear physics in the so-called Generator Coordinate Method (GCM) [22] when one wants to describe microscopically large collective motions of nuclei and specifically low-energy nuclear fission dynamics [4, 5, 7, 16].

Keywords and phrases. The time-dependent Schrödinger equation, the Crank–Nicolson finite-difference scheme, the Strang splitting, approximate and discrete transparent boundary conditions, stability, tunnel effect.

Several approaches have been developed in order to solve numerically such problems (see in particular, in the constant coefficients case [1–3, 8–10, 24, 25, 27]). One of them exploits the so-called discrete transparent boundary conditions (TBCs) on artificial boundaries [3, 13, 25]. Its advantages are the complete absence of spurious reflections, reliable computational stability, clear mathematical background and rigorous stability theory.

Concerning the discretization of the GSE, the Crank–Nicolson finite-difference scheme and more general schemes with the discrete TBCs in the case of a strip or semi-infinite strip was studied in detail in [9, 10, 34, 36]. However the scheme is implicit and solving a specific complex system of linear algebraic equations is required at each time level. In fact efficient methods to solve such systems are well developed by now in the real situation but not in the complex one. Only the particular case of all the coefficients (including the potential) independent of the coordinate $y$ perpendicular to the strip can be effectively implemented [34, 36]. On the other hand, the splitting technique has been widely used to simplify the resolution of the time-dependent Schrödinger and related equations (see in particular [6, 14, 15, 18–20]).

Our goal in this work is to apply the Strang-type splitting with respect to the potential to the Crank–Nicolson scheme with a sufficiently general approximate TBC in the form of the Dirichlet-to-Neumann map. The resulting method is more easy to implement but more difficult to study.

Developing the technique from [9], we prove its unconditional uniform in time $L^2$-stability and conservativeness under a condition on an operator $S$ in the approximate TBC. To construct the discrete TBC, we are obliged to consider the splitting scheme on an infinite mesh in the semi-infinite strip. Its uniform in time $L^2$-stability together with the mass conservation law are proved. We find that an operator $S_{\text{ref}}$ in the discrete TBC is the same as for the original Crank–Nicolson scheme in [9], and it satisfies the above mentioned condition so that the uniform in time $L^2$-stability of the resulting method is guaranteed. The non-local operator $S_{\text{ref}}$ is written in terms of the discrete convolution in time and the discrete Fourier expansion in direction $y$ perpendicular to the strip.

Due to the splitting, an effective direct algorithm using FFT in $y$ is developed to implement the method with the discrete TBC for general potential (while other coefficients are $y$-independent). The corresponding numerical results on the tunnel effect for rectangular barriers are presented together with the detailed practical error analysis in the uniform in time as well as $C$ and $L^2$ in space norms confirming the good error properties of the splitting scheme. This conclusion is very important since other splittings are able to deteriorate the error behavior essentially, in particular, see [29, 30, 32].

Finally we just mention that the previous results can be rather easily generalized to the case of a multi-dimensional parallelepiped infinite or semi-infinite in one of the space directions. Also the case of higher order in space splitting schemes with the discrete TBCs for the classical Schrödinger equation has been quite recently covered by another technique in [11, 33].

## 2. The Schrödinger equation on a semi-infinite strip and the splitting in potential Crank–Nicolson scheme with an approximate TBC

Let us consider the generalized 2D time-dependent Schrödinger equation

$$i\hbar \rho D_t \psi = (H_0 + V)\psi \quad \text{for} \quad (x, y) \in \Omega, \quad t > 0,$$

where $\Omega := (0, \infty) \times (0, Y)$ is a semi-infinite strip, involving the 2D Hamiltonian operator

$$H_0 \psi := -\frac{\hbar^2}{2} [D_x(B_{11}D_x\psi) + D_x(B_{12}D_y\psi) + D_y(B_{21}D_x\psi) + D_y(B_{22}D_y\psi)].$$

The real coefficients $\rho(x, y) > 0$, $B = \{B_{pq}(x, y)\}_{p,q=1}^2$ and $V(x, y)$ (the potential) are such that $\rho(x, y) \geq \rho > 0$ in $\Omega$ and the matrix $B$ is symmetric and positive definite uniformly in $\Omega$. Also $i$ is the imaginary unit, $\hbar > 0$ is a physical constant, $D_t$, $D_x$ and $D_y$ are partial derivatives, and the unknown wave function $\psi = \psi(x, t)$ is complex-valued.
We impose the following boundary condition, the condition at infinity and the initial condition

\[
\psi(\cdot, t)|_{\partial \Omega} = 0, \quad \|\psi(x, \cdot, t)\|_{L^2(0,Y)} \to 0 \quad \text{as} \quad x \to +\infty, \quad \text{for any} \quad t > 0,
\]

\[
\psi|_{t=0} = \psi^0(x, y) \quad \text{in} \quad \Omega.
\]

We also assume that

\[
B_{11}(x, y) = B_{1\infty} > 0, \quad B_{12}(x, y) = B_{21}(x, y) = 0, \quad B_{22}(x, y) = B_{2\infty} > 0,
\]

\[
\rho(x, y) = \rho_{\infty} > 0, \quad V(x, y) = V_{\infty}, \quad \psi^0(x, y) = 0 \quad \text{on} \quad \Omega, \Omega_X,
\]

for some \(X_0 > 0\), where \(\Omega_X := (0, X) \times (0, Y)\). It is well-known that solution to problem (2.1)–(2.4) satisfies a non-local integro-differential TBC for any \(x = X \geq X_0\) (for example see [9]) which we do not reproduce here.

Introduce a non-uniform mesh \(\bar{\omega}^\tau\) in \(t\) on \([0, \infty)\) with nodes \(0 = \tau_0 < \ldots < \tau_m < \ldots, \tau_m \to \infty\) as \(m \to \infty\), and steps \(\tau_m := t_m - t_{m-1}\). Let \(t_{m-1/2} = \frac{t_{m-1} + t_m}{2}\) and \(\omega^\tau := \bar{\omega}^\tau \setminus \{0\}\). In the differential case, the splitting in potential method can be represented as follows: three problems are solved sequentially step by step in time

\[
\begin{align*}
\text{ih}\rho D_t \tilde{V} &= (\Delta V) \tilde{V} \quad \text{on} \quad \Omega \times (t_{m-1/2}, t_m], \quad \tilde{V}|_{t=t_{m-1/2}} = \tilde{V}|_{t=t_{m-1}}, \\
\text{ih}\rho D_t \psi &= (H_0 \tilde{V}) \psi \quad \text{on} \quad \Omega \times (t_{m-1}, t_m], \quad \psi|_{t=t_{m-1}} = \psi|_{t=t_{m-1/2}}, \\
\tilde{\psi}|_{\partial \Omega} &= 0, \quad \|\tilde{\psi}(x, \cdot, t)\|_{L^2(0,Y)} \to 0 \quad \text{as} \quad x \to \infty, \quad \text{for} \quad t \in (t_{m-1}, t_m], \\
\text{ih}\rho D_t \psi &= (\Delta V) \psi \quad \text{on} \quad \Omega \times (t_{m-1/2}, t_m], \quad \psi|_{t=t_{m-1/2}} = \psi|_{t=t_{m}}, \\
\psi|_{t=0} &= \psi^0 \quad \text{in} \quad \Omega,
\end{align*}
\]

for any \(m \geq 1\), where \(\Delta V := V - \tilde{V}\) and \(\tilde{V}(x)\) is an auxiliary potential satisfying

\[
\tilde{V}(x) = V_{\infty} \quad \text{on} \quad [X_0, \infty).
\]

In the simplest case, \(\tilde{V}(x) = V_{\infty}\). But, in particular, to generalize results to the case of a strip and different constant values \(V_{\pm \infty}\) of \(V(x, y)\) at \(x \to \pm \infty\), it is necessary to take non-constant \(\tilde{V}\); see also Section 4 below.

The Cauchy problems (2.5) and (2.8) can be easily solved explicitly, in particular,

\[
\tilde{\psi}|_{t=t_{m-1/2}} = \exp\left\{-\frac{\text{i}\tau_m}{2\hbar \rho} \Delta V\right\} \tilde{\psi}|_{t=t_{m-1}}, \quad \psi|_{t=t_m} = \exp\left\{-\frac{\text{i}\tau_m}{2\hbar \rho} \Delta V\right\} \tilde{\psi}|_{t=t_m}.
\]

Equation in (2.6) is the original equation (2.1) simplified by substituting \(\tilde{V}\) for \(V\). Also \(\tilde{\psi}\) and \(\tilde{\psi}\) are auxiliary functions and \(\psi\) is the main unknown one. This is a version of the Strang-type splitting [19] (though the original Strang splitting [26] was suggested with respect to space derivatives for the 2D transport equation; note that sharp error bounds for the Strang splitting for the 2D heat equation can be found in [32]). The symmetrized three-step form of this splitting ensures its second order of approximation for \(\tilde{\psi}|_{t=t_m}\) with respect to \(\tau_m\).

We turn to the fully discrete case. Fix some \(X > X_0\) and introduce a non-uniform mesh \(\bar{\omega}_{h, \infty}\) in \(x\) on \([0, \infty)\) with nodes \(0 = x_0 < \ldots < x_J = X < \ldots\) and steps \(h_j := x_j - x_{j-1}\) such that \(x_{J-2} \geq X_0\) and \(h_j = h \equiv h_J\) for \(j \geq J\). Let \(\omega_{h, \infty} := \bar{\omega}_{h, \infty} \setminus \{0\}\), \(\omega_h := \{x_j\}_{j=0}^J\), \(\omega_h := \bar{\omega}_{h} \setminus \{0, X\}\) and \(h_{j+1/2} := \frac{h_j + h_{j+1}}{2}\).

We define the backward, modified forward and central difference quotients as well as two mesh averaging operators in \(x\)

\[
\begin{align*}
\overline{\partial}_x W_j := \frac{W_j - W_{j-1}}{h_j}, \quad \hat{\partial}_x W_j := \frac{W_{j+1} - W_j}{h_{j+1/2}}, \quad \hat{\circ} \partial_x W_j := \frac{W_{j+1} - W_j}{2h_{j+1/2}}, \\
\overline{\partial}_x W_j := \frac{W_{j+1} + W_j}{2}, \quad \hat{s}_x W_j := \frac{h_j W_j + h_{j+1} W_{j+1}}{2h_{j+1/2}}.
\end{align*}
\]
We define two mesh counterparts of the inner product in the complex space $L^2(0, X)$:

$$(U, W)_{\omega_h} := \sum_{j=1}^{J-1} U_j W_j^* h_{j+1/2}, \quad (U, W)_{\overline{\omega}_h} := (U, W)_{\omega_h} + U_j W_j^* \frac{h}{2}$$

and the associated mesh norms $\| \cdot \|_{\omega_h}$ and $\| \cdot \|_{\overline{\omega}_h}$ (of course, for mesh functions respectively defined on $\omega_h$ or defined on $\overline{\omega}_h$ and equal zero at $x_0 = 0$). Hereafter $z^*$, Re $z$ and Im $z$ denote the complex conjugate, the real and imaginary parts of $z \in \mathbb{C}$. The above averaging operators are related by an identity

$$(\hat{s}_x W, U)_{\omega_h} = \sum_{j=1}^{J} W_j (\overline{s}_x U_j^*) h_j - \frac{1}{2} (W_1 U_0^* h_1 + W_J U_J^* h_J). \quad (2.12)$$

We also introduce a non-uniform mesh $\overline{\omega}_\delta$ in $y$ on $[0, Y]$ with nodes $0 = y_0 < \ldots < y_K = Y$ and steps $\delta_k := y_k - y_{k-1}$. Let $\omega_\delta := \overline{\omega}_\delta \setminus \{0, Y\}$. We define the backward and modified forward difference quotients together with two mesh averaging operators in $y$

$$\overline{\delta}_y U_k := \frac{U_k - U_{k-1}}{\delta_k}, \quad \hat{\delta}_y U_k := \frac{U_{k+1} - U_k}{\delta_{k+1/2}}, \quad \overline{s}_y U_k := \frac{U_{k-1} + U_k}{2}, \quad \hat{s}_y U_k := \frac{\delta_k U_k + \delta_{k+1/2} U_{k+1}}{2\delta_{k+1/2}},$$

where $\delta_{k+1/2} := \frac{\delta_k + \delta_{k+1}}{2}$. Let $H(\overline{\omega}_\delta)$ be the space of functions $U: \overline{\omega}_\delta \to \mathbb{C}$ such that $U|_{k=0,K} = 0$, equipped with the inner product

$$(U, W)_{\omega_\delta} := \sum_{k=1}^{K-1} U_k W_k^* \delta_{k+1/2}$$

and the associated norm $\| \cdot \|_{\omega_\delta}$.

We define the product 2D meshes $\overline{\omega}_{h,\infty} := \overline{\omega}_{h,\infty} \times \overline{\omega}_\delta$ on $\overline{\Omega}$ and $\overline{\omega}_h := \overline{\omega}_h \times \overline{\omega}_\delta$ on $\overline{\Omega}_X$ as well as their interiors $\omega_{h,\infty} := \omega_{h,\infty} \times \omega_\delta$ and $\omega_h := \omega_h \times \omega_\delta$. Let $I_h := \{(0, y_k), 1 \leq k \leq K-1\} \cup \{(x_j, 0), (x_j, Y), 0 \leq j \leq J\}$ be a part of the boundary of $\overline{\omega}_h$.

Let $A_{-j,k} := A(x_{j-1/2}, y_{k-1/2})$, for all the coefficients $A = \rho, B_{pq}, V$, with $x_{j-1/2} := \frac{x_{j-1} + x_j}{2}$ and $y_{k-1/2} := \frac{y_{k-1} + y_k}{2}$. We exploit the 2D mesh Hamiltonian operator

$$\mathcal{H}_{0h} W := -\frac{\hbar^2}{2} \left[ \hat{\delta}_x \left( B_{11h} \overline{\delta}_x W \right) + \hat{\delta}_x \overline{\delta}_y \left( B_{21h} \overline{\delta}_x \overline{\delta}_y W \right) + \overline{\delta}_y \left( B_{12h} \overline{\delta}_x \overline{\delta}_y W \right) + \overline{\delta}_y \left( B_{22h} \overline{\delta}_x \overline{\delta}_y W \right) \right],$$

where the coefficients are given by formulas $B_{11h} = \hat{s}_y B_{11} - \hat{s}_x B_{12}, B_{21h} = \hat{s}_x B_{22} - \hat{s}_y B_{21}, B_{12h} = B_{21h}$. We also set $\rho_h = \hat{s}_x \rho \hat{s}_y, V_h = \hat{s}_x V \hat{s}_y$ and $\tilde{V}_h = \hat{s}_x \tilde{V} \hat{s}_y$. Actually this finite-difference discretization is a simplification of the bilinear finite element method for the rectangular mesh $\overline{\omega}_h$ (conserving, in particular, its $L^2(\Omega)$ and $H^1(\Omega)$ optimal error bounds), see [31]. Some other operators $\mathcal{H}_{0h}$ could be also exploited.

We define also the backward difference quotient and averaging in time

$$\overline{\delta}_t \Phi := \frac{\Phi^m - \Phi^{m-1}}{\tau_m}, \quad \overline{s}_t \Phi := \frac{\Phi^{m-1} + \Phi^m}{2}.$$

The following Crank–Nicolson-type scheme was studied in [9]

$$i \hbar \rho_h \overline{\delta}_t \Psi^m = (\mathcal{H}_{0h} + V_h) \overline{s}_t \Psi^m \quad \text{on} \quad \omega_h, \quad (2.13)$$

$$\Psi^m|_{t=0} = 0, \quad (2.14)$$

$$\left\{ \frac{\hbar^2}{2} B_{11h} \overline{\delta}_x \overline{s}_t \Psi + \frac{h}{2} \left[ i \hbar \rho_h \overline{\delta}_t \Psi + \left( \frac{\hbar^2}{2} B_{22h} \overline{\delta}_y \overline{\delta}_y - V_h \right) \overline{s}_t \Psi \right] \right\}^m_{j=0} = \frac{\hbar^2}{2} B_{11h} S^m \Psi^m_j, \quad (2.15)$$

$$\Psi^0 = \Phi_0^m \quad \text{on} \quad \overline{\omega}_h, \quad (2.16)$$
for any $m \geq 1$. Here the boundary condition (2.15) is the general approximate TBC posed on $\omega$, with a linear operator $S^m$ acting in the space of functions defined on $\omega \times \{ t \}_{j=1}^m$, and $\Psi^m = \{ \Psi^m_j \}$. Also $\Psi^0_{h,j} = \psi^0(x_j, y_k)$ (for definiteness) and thus $\Psi^0_{h,j} = 0$; we assume also that $\Psi^m_{h,j} = 0$ and the conjunction condition $\Psi^0_{h,j} = 0$ is valid.

Recall that the left-hand side in the approximate TBC (2.15) has the form of the well-known 2D second order approximation to $h^2/2 B_1 \omega D_x$ in the Neumann boundary condition (exploiting an 8-point stencil in all the directions $x$, $y$ and $t$).

We write down the following Strang-type splitting in potential for the Crank–Nicolson scheme (2.13)–(2.16)

\[
\begin{align*}
&\frac{i \hbar}{2} \left( \frac{\tilde{\Psi}^m - \tilde{\Psi}^{m-1}}{\tau_m} \right) = \Delta V_h \frac{\tilde{\Psi}^m + \tilde{\Psi}^{m-1}}{2} \quad \text{on } (\omega_h \cup x_j) \times \omega, \quad (2.17) \\
&\frac{i \hbar}{2} \left( \frac{\tilde{\Psi}^m - \tilde{\Psi}^m}{\tau_m} \right) = \left( \frac{\hbar_{1h} + \hbar_{h}}{2} \right) \frac{\tilde{\Psi}^m + \tilde{\Psi}^m}{2} + F^m \quad \text{on } \omega_h, \quad (2.18) \\
&\frac{i \hbar}{2} \left( \frac{\tilde{\Psi}^m - \tilde{\Psi}^m}{\tau_m} \right) = \Delta V_h \frac{\tilde{\Psi}^m + \tilde{\Psi}^m}{2} \quad \text{on } (\omega_h \cup x_j) \times \omega, \quad (2.19) \\
&\frac{\hbar}{2} \left( \frac{\tilde{\Psi}^m - \tilde{\Psi}^m}{\tau_m} \right) = \left( \hbar_{1h} + \hbar_{h} \right) \frac{\tilde{\Psi}^m + \tilde{\Psi}^m}{2} \quad \text{on } (\omega_h \cup x_j) \times \omega, \quad (2.20)
\end{align*}
\]

for any $m \geq 1$, where $\Delta V_h := V_h - \hbar_{h}$. We have added the perturbation $F^m$ into (2.18) and (2.21) in order to study stability of the scheme below in more detail (we suppose that $F^m$ is given on $\omega_h$ and $F^m(\omega_h) = 0$).

Obviously equations (2.17) and (2.19) are reduced to the explicit expressions

\[
\tilde{\Psi}^m = \hat{\epsilon}^m \tilde{\Psi}^{m-1}, \quad \Psi^m = \hat{\epsilon}^m \tilde{\Psi}^m, \quad \text{with } \hat{\epsilon}^m := \frac{1 - i \frac{\tau_m}{4 \hbar \rho_h} \Delta V_h}{1 + i \frac{\tau_m}{4 \hbar \rho_h} \Delta V_h}, \quad \text{on } (\omega_h \cup x_j) \times \omega.
\]

The main finite-difference equation (2.18) is similar to the original one (2.13) simplified by substituting $\hbar_{h}$ for $V_h$. Here $\tilde{\Psi}$ and $\Psi$ are auxiliary unknown functions and $\Psi$ is the main unknown one. We have got the approximate TBC (2.21) by substituting respectively

\[
\frac{\tilde{\Psi}^m + \tilde{\Psi}^m}{2}, \quad \frac{\tilde{\Psi}^m - \tilde{\Psi}^m}{\tau_m}, \quad \tilde{\Psi}^m
\]

for $\tilde{\Psi}, \tilde{\Psi}^m, \Psi$ and $\Psi^m$ in the approximate TBC (2.15); but notice that since $\Delta V_h(\omega) = 0$, actually

\[
\Psi^m_{j} = \Psi^m_{j-1}, \quad \Psi^m_{j} = \tilde{\Psi}^m_{j}, \quad \text{on } \omega \text{ for } m \geq 1.
\]

Clearly the constructed splitting in potential scheme can be also considered as the Crank–Nicolson-type discretization in time and the same approximation in space for the above splitting in potential differential problem (2.5)–(2.11). 

Also note that inserting formulas (2.23) into equation (2.18) (for $F = 0$) and excluding the auxiliary functions leads to the following equation for $\Psi$

$$i\hbar \rho_h \frac{(E^m)^{-1} \Psi^m - E^m \Psi^{m-1}}{\tau_m} = \left(\mathcal{H}_{0h} + \tilde{V}_h\right) \frac{E^m \Psi^{m-1} + (E^m)^{-1} \Psi^m}{2}$$

(2.25)

or, in another form,

$$\left[i\hbar \rho_h - \frac{\tau_m}{2} \left(\mathcal{H}_{0h} + \tilde{V}_h\right)\right] (E^m)^{-1} \Psi^m = \left[i\hbar \rho_h + \frac{\tau_m}{2} \left(\mathcal{H}_{0h} + \tilde{V}_h\right)\right] E^m \Psi^{m-1}.$$

(2.26)

Equation (2.25) can be considered as a non-standard discretization for the Schrödinger equation (2.1) whereas equation (2.26) can be viewed as a specific symmetric approximate factorization [28] with respect to the potential of the Crank–Nicolson equation (2.13).

We note that $E^{-1} = E^*$ and write down $E = E_R - 2\tau i E_I$ with real $E_R$ and $E_I$. Then

$$\frac{E^* \Psi - \Psi^*}{\tau} = E_R \frac{\partial I}{\partial t} \Psi + 4i E_I \frac{\partial I}{\partial t} \Psi, \quad \frac{E^* \Psi + \Psi^*}{2} = E_R \Phi + i \tau^2 E_I \frac{\partial I}{\partial t} \Psi.$$

Consequently we can rewrite equation (2.25) as follows

$$i\hbar \rho_h E_R \frac{\partial I}{\partial t} \Psi = \mathcal{H}_{0h} \left(E_R \Phi + i \tau^2 E_I \frac{\partial I}{\partial t} \Psi\right) + \left(E_R \tilde{V}_h + 4i \hbar \rho_h E_I \right) \Phi + i \tau^2 \tilde{V}_h \frac{\partial I}{\partial t} \Psi.$$

After some calculations, this formulation implies that the approximation error of the discrete equation (2.25) differs from the original one (2.13) by a term of the order $O \left(\tau^2_{\max}\right)$ (in particular, note that $E_R = 1 + O(\tau^2_{\max})$ and $4\hbar \rho_h E_I = \Delta V_h + O(\tau^2_{\max})$) as $\tau_{\max} \to 0$, where $\tau_{\max} := \sup_{m \geq 1} \tau_m$.

Since the Cauchy problems (2.5) and (2.8) do not need necessarily a discretization in time, to cover both formulas (2.11) and (2.23), below we also admit an expression

$$E^m = \exp \left\{-i \frac{\tau_m}{2\hbar \rho_h} \Delta V_h\right\}$$

(2.27)

in (2.23). Obviously in both cases $E^{-1} = E^*$ and $|E| = 1$.

We introduce two mesh counterparts of the inner product in the complex space $L^2(\Omega_N)$:

$$(U, W)_{\omega_h} := \sum_{j=1}^{J-1} \sum_{k=1}^{K-1} U_{jk} W_{jk}^* h_{j+1/2} \delta_{k+1/2}, \quad (U, W)_{\tau_h} := (U, W)_{\omega_h} + \sum_{k=1}^{K-1} U_{jk} W_{jk}^* \frac{h}{2} \delta_{k+1/2}$$

and the associated mesh norms $\| \cdot \|_{\omega_h}$ and $\| \cdot \|_{\tau_h}$.

**Proposition 2.1.** Let the operator $S$ satisfy an inequality [9]

$$\text{Im} \sum_{m=1}^{M} (S^m \Phi^m, \bar{\Phi}^m)_{\omega_h} \tau_m \geq 0 \text{ for any } M \geq 1,$$

(2.28)

for any function $\Phi: \bar{\Omega} \times \bar{\Omega}^* \to \mathbb{C}$ such that $\Phi^0 = 0$ and $\Phi_{|k=0,K} = 0$, where $\Phi^m = \{\Phi^1, \ldots, \Phi^m\}$. Then, for a solution of the splitting in potential scheme (2.17)–(2.22), the following stability bound holds

$$\max_{0 \leq m \leq M} \| \sqrt{\rho_h} \Psi^m \|_{\tau_h} \leq \| \sqrt{\rho_h} \Psi^0_h \|_{\tau_h} + \frac{2}{\hbar} \max_{m=1}^{M} \| \frac{E^m}{\sqrt{\rho_h}} \|_{\tau_h} \tau_m \text{ for any } M \geq 1.$$

(2.29)
Proof. We take the $(\cdot, \cdot)_{\omega h}$-inner-product of equation (2.18) with a function $W: \mathfrak{x}_h \to \mathbb{C}$ such that $W|_{\Gamma_h} = 0$. Then we sum the result by parts in $x$ and $y$ (using assumptions (2.4) and (2.10)), apply identity (2.12) and a similar identity with respect to $y$, exploit the approximate TBC (2.21) and obtain an identity

$$
\begin{align*}
\frac{\hbar}{2} \sum_{j=1}^K \sum_{k=1} B_{11,-} \left( \frac{\partial_x \tilde{\psi}^m + \tilde{\psi}^m}{2} \right) \partial_x \tilde{\psi}^m + B_{12,-} \left( \frac{\partial_x \tilde{\psi}^m + \tilde{\psi}^m}{2} \right) \partial_y \tilde{\psi}^m \\
+ \sum_{j} B_{21,-} \left( \frac{\partial_y \tilde{\psi}^m + \tilde{\psi}^m}{2} \right) \partial_x \tilde{\psi}^m + \sum_{j} B_{22,-} \left( \frac{\partial_y \tilde{\psi}^m + \tilde{\psi}^m}{2} \right) \partial_y \tilde{\psi}^m & \right) j_k \delta_k \\
+ \left( \frac{\tilde{\psi}^m + \tilde{\psi}^m}{2}, W \right) & \tag{2.30}
\end{align*}
$$

for any $m \geq 1$, see [9] for more details.

The sesquilinear form on the right-hand side containing the five terms with coefficients $\tilde{B}_{pq}$ and $\tilde{V}_h$ is Hermitian-symmetric. Thus choosing $W = \frac{\tilde{\psi}^m + \tilde{\psi}^m}{2}$ and separating the imaginary part of the result, we get

$$
\frac{\hbar}{2\tau_m} \left( \rho_h \tilde{\psi}^m, \tilde{\psi}^m \right)_{\omega_h} - \left( \rho_h \tilde{\psi}^m, \tilde{\psi}^m \right)_{\omega_h} = \text{Im} \left( \frac{\tilde{\psi}^m + \tilde{\psi}^m}{2}, \tilde{\psi}^m \right)_{\omega_h} - \frac{\hbar^2}{2} B_{11} \text{Im} \left( S^m \tilde{\psi}^m, \tilde{\psi}^m \right)_{\omega_h}.
$$

Owing to (2.20), (2.23) and (2.27) we have the pointwise equalities

$$
\tilde{\psi}^m = |\psi^m|, \quad |\psi^m| = \tilde{\psi}^m \quad \text{on} \quad \mathfrak{x}_h.
$$

Also taking into account equalities (2.24), we further derive

$$
\frac{\hbar}{2\tau_m} \left( \rho_h |\psi^m|^2 \right)_{\omega_h} - \left( \rho_h |\psi^m|^2 \right)_{\omega_h} = \text{Im} \left( \frac{|\psi^m|^2}{2}, \tilde{\psi}^m \right)_{\omega_h} - \frac{\hbar^2}{2} B_{11} \text{Im} \left( S^m \tilde{\psi}^m, \tilde{\psi}^m \right)_{\omega_h}.
$$

Multiplying both sides by $\frac{2\tau_m}{h}$ and summing up the result over $m = 1, \ldots, M$, we obtain

$$
\left( \sqrt{\rho_h} \psi^M \right)_{\omega_h}^2 + h B_{11} \sum_{m=1}^M \text{Im} \left( S^m \psi^m, \tilde{\psi}^m \right)_{\omega_h} \tau_m = \left( \sqrt{\rho_h} |\psi^M|^2 \right)_{\omega_h} + \frac{h}{2} B_{11} \text{Im} \left( S^m \psi^m, \tilde{\psi}^m \right)_{\omega_h}.
$$

Applying inequality (2.28) and then equalities (2.31), we get

$$
\left( \sqrt{\rho_h} |\psi^M| \right)_{\omega_h}^2 \leq \left( \sqrt{\rho_h} |\psi^M| \right)_{\omega_h}^2 + \frac{h}{2} \sum_{m=1}^M \text{Im} \left( \rho_h \tilde{\psi}^m \right)_{\omega_h} \tau_m \left( \max_{1 \leq m \leq M} \left| \sqrt{\rho_h} \tilde{\psi}^m \right|_{\omega_h} + \max_{1 \leq m \leq M} \left| \sqrt{\rho_h} |\psi^M|^2 \right|_{\omega_h} \right)
$$

$$
\leq \left( \sqrt{\rho_h} |\psi^M| \right)_{\omega_h}^2 + \frac{h}{2} \sum_{m=1}^M \left( \frac{F^m}{\rho_h} \right)_{\omega_h} \tau_m \max_{0 \leq m \leq M} \left| \sqrt{\rho_h} |\psi^M|^2 \right|_{\omega_h}.
$$

This directly implies bound (2.29). \hspace{1cm} \Box

**Corollary 2.2.** Let condition (2.28) be valid. Then the splitting in potential scheme (2.17)–(2.22) is uniquely solvable.

In particular, for $F = 0$ its solution satisfies an equality

$$
\max_{m \geq 0} \left| \sqrt{\rho_h} \psi^m \right|_{\omega_h} = \left| \sqrt{\rho_h} \psi^0 \right|_{\omega_h}.
$$

(2.33)
Proof. The unique solvability follows from a priori bound (2.29), and equality (2.33) also is clear from (2.29) for $F = 0$.

Remark 2.3. We emphasize that actually both the Crank–Nicolson scheme and the splitting in potential scheme can be similarly considered and studied not only for the strip geometry but for much more general unbounded domains $\Omega$ composed of rectangles with sides parallel to coordinate axes and having one or more separated semi-infinite strip outlets at infinity.

3. The splitting in potential Crank–Nicolson scheme on the infinite space mesh and the discrete TBC

To construct the discrete TBC, it is required to consider the splitting in potential Crank–Nicolson scheme on the infinite space mesh for the original problem (2.1)–(2.4) on the semi-infinite strip

\begin{align}
\frac{i\hbar\phi_h^m - \phi_h^{m-1}}{\tau_m/2} &= \Delta V_h \frac{\psi_h^m + \psi_h^{m-1}}{2} \quad \text{on} \quad \omega_h, \infty, \\
\frac{i\hbar\phi_h^m - \phi_h^m}{\tau_m} &= \left(\mathcal{H}_{0,\hbar} + \mathcal{V}_h\right) \frac{\psi_h^m + \psi_h^{m-1}}{2} + F^m \quad \text{on} \quad \omega_h, \infty, \\
\frac{i\hbar\phi_h^m - \phi_h^m}{\tau_m/2} &= \Delta V_h \frac{\psi_h^m + \psi_h^{m-1}}{2} \quad \text{on} \quad \omega_h, \infty, \\
\psi_h^m|_{\Gamma_{h,\infty}} &= 0, \quad \psi_h^m|_{\Gamma_{h,\infty}} = 0, \quad \psi_h^m|_{\Gamma_{h,\infty}} = 0, \\
\psi_h^0 &= \psi_h^0 \quad \text{on} \quad \omega_h, \infty,
\end{align}

for any $m \geq 1$, where $\Gamma_{h,\infty} := \omega_h \setminus \omega_h, \infty$. The perturbation $F^m$ is given on $\omega_h, \infty$ after setting $F^m|_{\Gamma_{h,\infty}} = 0$; it is added to the right-hand side of the main equation (3.2) once again to study stability in more detail.

Obviously once again equations (3.1) and (3.3) are reduced to explicit expressions (2.23) which are valid now on $\omega_h, \infty$. We continue to admit expression (2.27) in (2.23).

Let $H_h$ be a Hilbert space of mesh functions $W: \omega_h, \infty \rightarrow \mathbb{C}$ such that $W|_{\Gamma_{h,\infty}} = 0$ and $\sum_{j=1}^\infty \|W_j\|_{\omega_j}^2 < \infty$, equipped with the inner product

$$(U, W)_{H_h} := \sum_{j=1}^\infty \sum_{k=1}^{K-1} U_{jk} W_{jk}^* h_{j+1/2}^\sigma h_{j+1/2}^\delta.$$ 

Proposition 3.1. Let $F^m, \psi_h^0 \in H_h$ for any $m \geq 1$. Then there exists a unique solution to the splitting in potential scheme (3.1)–(3.5) such that $\psi^m \in H_h$ for any $m \geq 0$, and the following stability bound holds

\begin{align}
\max_{0 \leq m \leq M} \|\sqrt{\rho_h} \psi^m\|_{H_h} &\leq \|\sqrt{\rho_h} \psi_h^0\|_{H_h} + \frac{2}{\hbar} \sum_{m=1}^M \left\|F^m\right\|_{H_h} + \frac{\tau_m}{\sqrt{\rho_h}} \quad \text{for any} \quad M \geq 1. 
\end{align}

Moreover, in the particular case $F = 0$, the mass conservation law holds

\begin{align}
\|\sqrt{\rho_h} \psi^m\|_{H_h}^2 &= \|\sqrt{\rho_h} \psi_h^0\|_{H_h}^2 \quad \text{for any} \quad m \geq 1. 
\end{align}

Proof. Given $\psi^m, F^m \in H_h$, there exists a unique solution $\psi^m \in H_h$ to equation (3.2). The much more general result was established in the proof of the corresponding Proposition 3 in [36]. Since expressions (2.23) are valid now on $\omega_h, \infty$, this implies existence of a unique solution to the splitting scheme (3.1)–(3.5) such that $\psi^m \in H_h$ for any $m \geq 0$. 

We set $\mathcal{H}_{0h} W := \mathcal{H}_{0h} W$ on $\omega_{h,\infty}$ and $\mathcal{H}_{0h} W := 0$ on $\Gamma_{h,\infty}$. The operator $\mathcal{H}_{0h}$ is bounded and self-adjoint in $H_{0h}$ since

$$\begin{align*}
\left(\mathcal{H}_{0h} U, W \right)_{H_{0h}} &= \frac{\hbar^2}{2} \sum_{j=1}^{\infty} \sum_{k=1}^{K} \left\{ B_{11, j} \bar{\sigma}_y \left[ (\partial_x U) \bar{\sigma}_x W^* + B_{12, j} \left( \bar{\sigma}_y U \right) \bar{\sigma}_x \bar{\sigma}_y W^* \right] + B_{21, j} \bar{\sigma}_y U \bar{\sigma}_x W^* + B_{22, j} \left[ (\partial_y U) \bar{\sigma}_y W^* \right] \right\} j_k h_{\delta k} \, h_{\sigma k} \, \delta_{\delta k},
\end{align*}$$

for any $U, W \in H_{0h}$, see [9] for details.

From equation (3.2) an identity

$$i\hbar \left( \mathcal{H}_{0h} \frac{\tilde{\psi}^m - \tilde{\psi}^m}{\tau_m} , W \right)_{H_{0h}} = \left( \mathcal{H}_{0h} \frac{\tilde{\psi}^m + \tilde{\psi}^m}{2} , W \right)_{H_{0h}}$$

follows, for any $m \geq 1$ and $W \in H_{0h}$. Acting in the spirit of the proof of Proposition 2.1, i.e. choosing $W = \frac{\tilde{\psi}^m + \tilde{\psi}^m}{2}$, separating the imaginary part of the result and applying the pointwise equalities (2.31) that are valid now on $\omega_{h,\infty}$, we get

$$\frac{\hbar}{2\tau_m} \left( \| \sqrt{\rho_h} \psi^m \|^2_{H_{0h}} - \| \sqrt{\rho_h} \psi^{m-1} \|^2_{H_{0h}} \right) = \text{Im} \left( \frac{F^m}{2} \frac{\tilde{\psi}^m + \tilde{\psi}^m}{2} \right).$$

Multiplying both sides by $\frac{2\tau_m}{\hbar}$ and summing up the result over $m = 1, \ldots, M$, we obtain

$$\| \sqrt{\rho_h} \psi^M \|^2_{H_{0h}} = \| \sqrt{\rho_h} \psi^0 \|^2_{H_{0h}} + \frac{2}{\hbar} \sum_{m=1}^{M} \text{Im} \left( \frac{F^m}{2} \frac{\tilde{\psi}^m + \tilde{\psi}^m}{2} \right).$$

(3.8)

The rest of the proof in fact repeats one for Proposition 2.1.

**Corollary 3.2.** Let $F^m = 0$ and $\psi^0 = 0$ on $\omega_{h,\infty} \setminus \omega_h$, for any $m \geq 1$. If the solution to the splitting in potential scheme (3.1)–(3.5) is such that $\psi^m \in H_{0h}$, for any $m \geq 0$, and satisfies an equation

$$\frac{\tau_m}{\hbar} \left| \begin{array}{c}
\partial_x \left( \frac{\tilde{\psi}^m + \tilde{\psi}^m}{2} \right) \\
\partial_y \left( \frac{\tilde{\psi}^m + \tilde{\psi}^m}{2} \right)
\end{array} \right|_{j = j} = S^m \psi^m_j \text{ on } \omega_{h}, \text{ for any } m \geq 1,$$

(3.9)

with some operator $S^m = S^m_{\text{ref}}$, then the following equality holds, for any $M \geq 1$

$$\hbar B_{1\infty} \text{Im} \sum_{m=1}^{M} (S^m_{\text{ref}} \psi^m_j, \psi^m_j)_{\omega_{h,\infty}} \tau_m = \left\| \psi^M \right\|^2_{\omega_{h,\infty} \setminus \omega_h} := \frac{\hbar}{2} \left\| \psi^M \right\|^2_{\omega_{h,\infty} \setminus \omega_h} + \sum_{j=J+1}^{\infty} \left\| \psi^M_j \right\|^2_{\omega_{h,\infty} \setminus \omega_h} \hbar \geq 0.$$

**Proof.** Similarly to [9], equation (3.9) is equivalent to the approximate TBC (2.22) provided that equation (3.2) is valid for $j = J$ with $F^J_{j = J} = 0$. Thus the solution to the splitting scheme (3.1)–(3.5) on the infinite mesh $\omega_{h,\infty}$ is the solution to the splitting scheme (2.17)–(2.22) on the finite mesh $\omega_h$, too. Then equality (3.2) is obtained by subtracting (3.22) from (3.8).

Equality (3.2) clarifies the energy sense of inequality (2.28) for $S^m = S^m_{\text{ref}}$ since

$$\left\| W \right\|^2_{H_{0h}} = \left\| W \right\|^2_{\omega_{h}} + \left\| W \right\|^2_{\omega_{h,\infty} \setminus \omega_h} \text{ for any } W \in H_{0h}.$$

By definition, the operator $S^m_{\text{ref}}$ that has just appeared implicitly corresponds to the discrete TBC. Let us describe it explicitly.
Let \( \omega_{h,j,0,\infty} := \{x_j\}_{j=0}^\infty \). Then \( \Delta V_h = 0 \) on \( \omega_{h,J-1,\infty} \times \omega_h \) and clearly
\[
\tilde{\psi}^m = \psi^{m-1}, \quad \psi^m = \tilde{\psi}^m \text{ on } \omega_{h,J-1,\infty} \times \omega_h, \quad \text{for any } m \geq 1.
\]
Therefore, if \( \psi_h^m = 0 \) on \( \omega_{h,J-1,\infty} \times \omega_h \) and \( F^m = 0 \) on \( \omega_{h,J,\infty} \times \omega_h \) for any \( m \geq 1 \), the splitting in potential scheme (3.1)–(3.5) is reduced on \( \omega_{h,J-1,\infty} \times \omega_h \) to the following auxiliary problem
\[
\begin{align*}
\text{(3.10)} & \quad \text{for any } m \geq 1. \\
H_{0h,\infty} W := -\frac{\hbar^2}{2} \left( B_{1\infty} \hat{\partial}_x \bar{\psi}_x W + B_{2\infty} \hat{\partial}_y \bar{\psi}_y W \right) \quad \text{on } \omega_{h,\infty} \setminus \omega_h \\
H_{0h,\infty} W := -\frac{\hbar^2}{2} \left( B_{1\infty} \hat{\partial}_x \bar{\psi}_x W + B_{2\infty} \hat{\partial}_y \bar{\psi}_y W \right) \quad \text{on } \omega_{h,\infty} \setminus \omega_h \\
H_{0h,\infty} W := -\frac{\hbar^2}{2} \left( B_{1\infty} \hat{\partial}_x \bar{\psi}_x W + B_{2\infty} \hat{\partial}_y \bar{\psi}_y W \right) \quad \text{on } \omega_{h,\infty} \setminus \omega_h
\end{align*}
\]
with constant coefficients. Moreover, equation (3.9) takes the simplified form
\[
\left( \partial^\omega_{x} \bar{\psi}_j \psi^m \right)_{j=J} = S^m \psi_j^m \quad \text{on } \omega_h, \quad \text{for any } m \geq 1.
\]
also involving the above transforms $F$ and $F^{-1}$ in $y$. Expressions for the kernel sequences $R_l$, $1 \leq l \leq K - 1$, can be found in [9], and we do not reproduce them here (see also [12, 13] for practically more convenient recurrence relations).

**Proposition 3.3.** The operator $S_{\text{ref}}$ satisfies inequality (2.28), see [9].

Thus for the solution of the splitting in potential scheme (2.17)–(2.22) with the discrete TBC (i.e. with $S = S_{\text{ref}}$), the stability bound (2.29) holds.

If the matrix $B$ is diagonal and $y$-independent together with $\rho$ as well as the mesh $\mathcal{J}_\delta$ is uniform, the splitting in potential scheme (2.17)–(2.22) with the discrete TBC can be effectively implemented. Indeed, then (omitting $F$ for simplicity) we can apply $F$ to the main equation (2.18) and the discrete TBC (2.21) with $S = S_{\text{ref}}$, take into account the boundary condition $\Psi^m|_{I_h} = 0$ (2.21) and formula (3.14) and obtain a collection of 1D disjoint problems (with tridiagonal matrices):

\[
\frac{i\hbar \rho_h}{\tau} \tilde{\psi}^{m(l)} = -\frac{\hbar^2}{2} \hat{\partial}_x \left( B_{11h} \tilde{\psi}^{m(l)} + \tilde{\psi}^{m(l)} \right) + \tilde{V}_l \frac{\tilde{\psi}^{m(l)} + \tilde{\psi}^{m(l)}}{2} \text{ on } \omega_h, \quad (3.15)
\]

\[
\tilde{\psi}^{m(l)} \bigg|_{j=0} = 0, \quad (3.16)
\]

\[
\left\{ \frac{\hbar^2}{2} B_{11\infty} \tilde{\psi}^{m(l)} + \tilde{\psi}^{m(l)} \right\} - \frac{\hbar}{2} \left[ i\hbar \rho_{\infty} \frac{\tilde{\psi}^{m(l)} - \tilde{\psi}^{m(l)}}{\tau} - \tilde{V}_l \frac{\tilde{\psi}^{m(l)} + \tilde{\psi}^{m(l)}}{2} \right] \bigg|_{j=J} = \frac{\hbar^2}{2} B_{1\infty} \frac{1}{2h} \left( R_l + \tilde{\Psi}_{lJ}^{(l)} \right)^m, \quad (3.17)
\]

with $1 \leq l \leq K - 1$, for any $m \geq 1$, where

\[
\tilde{V}_l := \frac{\hbar^2}{2} B_{2\infty} \lambda_{l\delta} + \tilde{V}, \quad \tilde{\Psi}_{lJ}^{(l)} = \left\{ \tilde{\psi}_{lJ}^{(l)}, \ldots, \tilde{\psi}_{lJ}^{(l)} \right\}.
\]

Given $\Psi^{m-1}$, the direct algorithm for computing $\Psi^m$ comprises five steps.

1. $\tilde{\psi}^m$ is computed on $(\omega_h \cup x, j) \times \omega_\delta$ according to (2.23).
2. $\left\{ \tilde{\psi}^m_{lJ}^{(l)} \right\}_{l=1}^{K-1}$ is computed by applying $F$ for any $1 \leq j \leq J$.
3. $\left\{ \tilde{\psi}^{m(l)}_{lJ} \right\}_{l=1}^{K-1}$ is computed by solving problem (3.15)–(3.17) for any $1 \leq l \leq K - 1$.
4. $\left\{ \tilde{\psi}^{m(l)}_{lJ} \right\}_{l=1}^{K-1}$ is computed by applying $F^{-1}$ for any $1 \leq j \leq J$.
5. $\Psi^m$ is computed on $(\omega_h \cup x, j) \times \omega_\delta$ according to (2.23).

Steps 1 and 5 require $O(JK)$ arithmetic operations, steps 2 and 4 require $O(JK \log_2 K)$ operations using FFT provided that $K = 2^p$ with the integer $p$, and step 3 requires $O((J + m)K)$ operations. The total amount of operations is $O((J \log_2 K + m)K)$ for computing the solution on the time level $m$ and $O((J \log_2 K + M)KM)$ for computing the solution on $M$ time levels $m = 1, \ldots, M$.

Notice that the algorithm essentially enlarges possibilities of the corresponding one in [34, 36] and also is highly parallelizable.

### 4. Numerical experiments

We have implemented the above algorithm. For numerical experiments, similarly to [35], we take $\rho(x, y) \equiv 1$, $H_0 = -\Delta$ (the minus 2D Laplace operator), $h = 1$ and a simple rectangular potential-barrier

\[
V(x, y) = \begin{cases} 
Q & \text{for } (x, y) \in (a, b) \times (c, d), \\
0 & \text{otherwise},
\end{cases} \quad Q > 0.
\]
On the other hand, from the numerical point of view, this barrier is not so simple since it is discontinuous and thus the corresponding exact solution is not smooth. Below we take the fixed \((a, b) = (1.6, 1.7)\) and \((c, d)\) of three different lengths in Examples A, B and C.

Let the initial function be the Gaussian wave packet

\[ \psi_0(x, y) = \psi_G(x, y) \equiv \exp\left\{i\sqrt{2}k(x - x^{(0)}) - \frac{(x - x^{(0)})^2 + (y - y^{(0)})^2}{4\alpha}\right\} \]  

on \(\mathbb{R}^2\).

We choose the parameters \(k = 30\) and \(\alpha = \frac{1}{120}\).

We solve the initial boundary value problem in the infinite strip \(\mathbb{R} \times (0, Y)\), choose the computational domain \(\bar{\Omega} \times [0, T]\) such that \((a, b)\) and \((c, d)\) are small enough outside \(\bar{\Omega}\). Namely, below \(X = 3\) and \(Y = 2.8\) together with \((x^{(0)}, y^{(0)}) = (1, \frac{Y}{2})\) as well as \(T = t_M = 0.027\). We use the uniform meshes in \(x, y\) and \(t\) with steps respectively \(h = \frac{X}{J}\), \(\delta = \frac{Y}{K}\) and \(\tau = \frac{T}{M}\).

We accordingly modify the splitting in potential scheme (2.17)–(2.22) replacing \(\omega_h \cup x_J\) by \(\bar{\omega}_h\) in (2.17) and (2.19), the boundary conditions (2.20) by

\[ \tilde{\psi}^m|_{k=0, K} = 0, \quad \bar{\omega}^m|_{k=0, K} = 0, \quad \bar{\psi}^m|_{k=0, K} = 0 \quad \text{on} \quad \bar{\omega}_h \]

together with the left discrete TBC at \(j = 0\) similar to the right one (2.21) for \(S = S_{\text{ref}}\). On Figure 1 the modulus and the real part of \(\psi_G\) are shown on the computational domain. The normalized barrier (with \(Q = 1\)) is situated there as well, for \((c, d) = (0.7, 2.1)\) (see Example B below).

**Example A.** We first take \((c, d) = (0, Y)\) and \(Q = 1500\) (previously the same example was in fact treated in [35] by a method from [34, 36]). In this case, the wave packet is divided into two similar reflected and transmitted parts moving in opposite directions with respect to the barrier. A little bit surprisingly, the solution is almost the same as in the case \((c, d) = \left(\frac{Y}{4}, \frac{3Y}{4}\right)\) in Example B (that is why the corresponding graphs of the solution are given below). Namely, for the fine mesh with \((J, K, M) = (9600, 512, 4800)\), norms of differences between the pseudo-exact solution for \((c, d) = (0, Y)\) computed by the Crank–Nicolson scheme and one for \((c, d) = \left(\frac{Y}{4}, \frac{3Y}{4}\right)\) computed by the splitting in potential scheme are

\[ E_C \approx 1.81 \times 10^{-3}, \quad E_{L^2} \approx 5.02 \times 10^{-4}, \]
i.e., they are actually small. In this section, we exploit the splitting method with the simplest choice $\tilde{V} = 0$ unless the contrary is explicitly stated. Hereafter $E_C$ and $E_{L^2}$ denote differences/errors in the mesh norms that are uniform in time as well as $C$ (i.e. uniform) and $L^2$ in space.

Notice also that the norms of differences between the pseudo-exact solutions on the fine mesh and on the mesh with $(J, K, M) = (1200, 64, 600)$ are

$$E_C \approx 2.70 \times 10^{-2}, \quad E_{L^2} \approx 1.65 \times 10^{-2},$$

for the Crank–Nicolson scheme, and

$$E_C \approx 2.54 \times 10^{-2}, \quad E_{L^2} \approx 1.60 \times 10^{-2},$$

for the splitting scheme (see also Fig. 2 below for more detail), i.e., they are small enough and close to each other.

**Example B.** Next we consider the barrier with $(c, d) = (\frac{3}{4}, \frac{3}{4}) = (0.7, 2.1)$ (that is one-half in length of the first one), for three values of the barrier height $Q$, in order to get qualitatively varying behavior of solutions (compare with [35]).

First, once again we take the barrier height $Q = 1500$. We exploit the mesh with $(J, K, M) = (1200, 64, 600)$ so that $h = 2.5 \times 10^{-3}$, $\delta = 4.375 \times 10^{-2}$ and $\tau = 4.5 \times 10^{-5}$. Though $J/K \approx 19$ is large, we qualify that such choice is reasonable. In particular, for comparison we exploit the above mentioned pseudo-exact solution on the fine mesh with $(J, K, M) = (9600, 512, 4800)$ that all three are 8 times larger and imply the steps $h = 3.125 \times 10^{-4}$, $\delta \approx 5.469 \times 10^{-3}$ and $\tau = 5.625 \times 10^{-6}$. Figure 2 demonstrates the behavior of the absolute and relative errors in $C$ and $L^2$ space mesh norms in dependence with time.

The modulus and the real part of the numerical solution $\Psi^m$ are given on Figure 3, for the time moments $t_m = m\tau$, $m = 180, 300, 420$ and 600. In this case, the wave packet is divided into two rather similar reflected and transmitted parts moving in opposite directions with respect to the barrier.

We continue to study the error behavior in more detail in Table 1. It contains errors of the solutions to the splitting method for increasing $J$, $K$ and $M$ respectively (for sufficiently large values of two other numbers). The associated ratios $R_C$ and $R_{L^2}$ of the sequential errors are also put there. They are rather close to 4 excluding the last rows that means almost the second order of convergence with respect to each of $J$, $K$ and $M$, both in $C$.
**Figure 3.** Example B ($Q = 1500$). The modulus and the real part of the numerical solution $\Psi^m$ for $(J, K, M) = (1200, 64, 600)$.

**Table 1.** Example B ($Q = 1500$). Errors, ratios of errors and ratios of runtimes in dependence with $J$ (for $K = 256$ and $M = 2400$), $K$ (for $J = 4800$ and $M = 2400$) or $M$ (for $J = 4800$ and $K = 256$).

</table>

and $L^2$ mesh norms. The deterioration of $R_C$ and $R_{L^2}$ in the last rows is explained by more essential influence of the errors due to the chosen discretization in other directions.

The last columns in the tables contain also the respective ratios of runtimes. One can see that they all are close to 2 when any of $J$, $K$ or $M$ increases twice.

In Table 2 we put $C$ and $L^2$ errors for some selected values of $J$, $K$ and $M$. They all decrease monotonically as $J$, $K$ or $M$ increase. We also compare there the numerical solutions of the splitting method with $\tilde{V} = 0$ and $V(x) = Q\chi(x)$, where $\chi(x)$ is the characteristic function of the interval $(a, b)$; two last columns of the table contain percentages

$$P_C := \left( \frac{E_C|_{\tilde{V} = 0}}{E_C|_{\tilde{V} = Q\chi}} - 1 \right) \times 100\%, \quad P_{L^2} := \left( \frac{E_{L^2}|_{\tilde{V} = 0}}{E_{L^2}|_{\tilde{V} = Q\chi}} - 1 \right) \times 100\%.$$

One can see that the second choice $\tilde{V} = Q\chi$ also works but the first one $\tilde{V} = 0$ mostly leads to better results.

In addition, for the fine mesh with $(J, K, M) = (9600, 512, 4800)$ the norms of differences between the solutions for these two different $\tilde{V}$ are

$$E_C \approx 3.32 \times 10^{-5}, \quad E_{L^2} \approx 1.04 \times 10^{-5},$$

$i.e.$, they are very small.

Second, we take a less barrier height $Q = 1000$. This situation is simpler from the numerical point of view. The numerical results are demonstrated on Figure 4 for the same time moments and the mesh. Now the wave packet goes through the barrier with an essentially less reflection.

Third, let $Q = 4000$ be rather large. On Figure 5 the numerical solution is represented for the same time moments and the mesh. Here the main part of the wave is reflected from the barrier and then moves in the opposite direction along the $x$ axis.

To check the approximate solution in this case, we compute how the numerical solution changes when any of $J$, $K$ or $M$ increases twice, see Table 3, where the corresponding absolute and relative errors in $C$ and $L^2$ norms are given. The relative errors $E_{C,rel}$ and $E_{L^2,rel}$ are defined as the maximal in time relative $C$ and $L^2$ mesh errors in space (in joint nodes). One can see that all the errors are small enough.

We emphasize that on all Figures 3–5, the last two graphs exhibit complete absence of the spurious reflections from the artificial left and right boundaries due to exploiting of the discrete TBCs there.

**Example C.** We also treat the case of a very short barrier with $(c, d) = \left( \frac{1}{2}, \frac{1}{2}, \frac{1}{10}, \frac{1}{5} \right) = (1.3125, 1.4875)$ and once again having the height $Q = 1500$; this barrier looks like a column. The numerical solution $\Psi^m$ is represented on Figure 6, for the time moments $t_m = m\tau$, $m = 180, 240, 300$ and 360, together with the normalized barrier. We use the mesh with $(J, K, M) = (1200, 512, 600)$, $i.e.$ for the same $J$ and $M$ as on the above figures but for notably larger $K$. Now in contrast to the previous examples, the transmitted part of the wave packet is separated into two pieces.

To check the approximate solution in this case, we compute how the numerical solution changes when $J$, $K$ or $M$ increases twice, see Table 4, where the corresponding absolute and relative errors are given. One can see that all of them are small enough once again.

We call attention to the essentially more complicated behavior of the real part of the solution compared to its modulus in all Examples A–C. Comparing $C$ and $L^2$ errors, one can see that though $C$ errors are mainly larger, their behavior is rather similar that is not so obvious a priori taking into account the oscillatory type of the solutions in space and time.

In general, the above practical error analysis indicates the good error properties of the splitting in potential scheme.
Finally, note that clearly both the rectangular form of the barrier and the specific choice of the initial function are inessential to apply efficiently the splitting method.

Acknowledgements. The paper was initiated during the visit of A. Zlotnik in summer 2011 to the the Département de Physique Théorique et Appliquée, CEA/DAM/DIF Ile de France (Arpajon), which he thanks for hospitality. The study is carried out by him within The National Research University Higher School of Economics‘ Academic Fund Program in 2012-2013, research Grant No. 11-01-0051. Both A. Zlotnik and I. Zlotnik are supported by the Ministry of Education and Science of the Russian Federation (Contract 14.B37.21.0864) and the Russian Foundation for Basic Research, Project 14-01-90009-Bel.
