STEPHEN WAINGER

On Vinogradov’s estimate of trigonometric sums and the Goldbach-Vinogradov theorem

<http://www.numdam.org/item?id=MSMF_1971__25__173_0>
ON VINOGRA DOV'S ESTI MATE OF TRIGONOMETRIC SUMS
AND THE GOLDBACH-VINOGRADOV THEOREM

by

Stephen WAINGER

--- :

The purpose of this lecture is to give an expository account of the principle
ideas involved in Vinogradov's estimate for

\[ S_n(\theta) = \sum_{p \leq n} e^{2\pi i p \theta} \]

(in the above summation and throughout p is a prime).

However, before we begin to estimate \( S_n(\theta) \), we indicate why the estimates for
for \( S_n(\theta) \) are so important for the proof of the Goldbach-Vinogradov theorem.

**THEOREM.** (Goldbach-Vinogradov). - Every sufficiently large odd integer is the sum
of three primes.

We define \( r(n) \) to be the number of ways to write \( n \) as a sum of three primes.
Then the first step of the proof is to observe

\[ r(n) = \int_0^1 e^{-2\pi \sin \theta} \left[ S_n(\theta) \right]^3 d\theta \]

To see 1), observe

\[ [S_n(\theta)]^3 = \sum_{p_1 \leq n} \sum_{p_2 \leq n} \sum_{p_3 \leq n} e^{2\pi i (p_1 + p_2 + p_3) \theta} \]

so interchanging the order of summation and integration, we observe that the right
hand side of 1), is

\[ \sum_{p_1 \leq n} \sum_{p_2 \leq n} \sum_{p_3 \leq n} \int_0^1 e^{-2\pi i (n - (p_1 + p_2 + p_3)) \theta} \] 

The above integral is 1 if \( n = p_1 + p_2 + p_3 \) and 0 otherwise. So the triple sum
above just counts the number of ways to write \( n \) as \( p_1 + p_2 + p_3 \). This is \( r(n) \),
and the proof of 1) is complete.

The idea of (essentially) Hardy and Littlewood is that
\[ r(n) = \int_{V_n} e^{-2\pi i n \theta} \left[ S_n(\theta) \right]^3 \, d\theta \]

\[ + \int_{V_n} e^{-2\pi i n \theta} \left[ S_n(\theta) \right]^3 \, d\theta = M_n + E_n. \]

\( V_n \) is the union of some very small disjoint intervals which we shall describe later. What is important for us now is that for every \( \theta \) in \( V_n \),

\[ \theta = \frac{a}{q} + \frac{e}{q^2} \quad \text{with} \quad (a, q) = 1, \quad |e| \leq 1 \]

and what is very important

2) \[ (\log n)^u \leq q \leq \frac{n}{(\log n)^u} \]

where \( u \) is some fixed large integer like 100.

Now one may show that

3) \[ M_n > \frac{cn^2}{(\log n)^3} \]

for \( n > N_0 \) and \( n \) odd. (We give some indication of this at the end of our lecture).

The main difficulty in the proof is to prove

4) \[ E_n = o\left(\frac{n^2}{(\log n)^3}\right). \]

Formulas 3) and 4) of course give the Goldbach-Vinogradov Theorem.

The method of Hardy and Littlewood also dictates the general approach of estimating \( E_n \). Namely

5) \[ |E_n| \leq \sup_{\theta \in V_n} |S_n(\theta)| \int_0^1 |S_n(\theta)|^2 \, d\theta. \]

By Pavseval's equality the integral in 5) is \( \pi(n) \) (the number of primes equal to or less than \( n \)). So using the simple estimate

\[ \pi(n) \leq \frac{cn}{\log n}, \quad \text{we have} \]

6) \[ E_n \leq \frac{cn}{\log n} \sup_{\theta \in V_n} |S_n(\theta)|. \]

Notice then to prove 4), we need to show

7) \[ |S_n(\theta)| = o\left(\frac{n}{\log n}\right). \]

Of course trivially
On Vinogradov's estimate 175

\[ |S_n(\theta)| \leq k \frac{n}{\log n}, \]

so we need only a very modest improvement of the trivial estimate, but this small improvement was very difficult. Vinogradov's method proves the following:

**THEOREM.** If \( \theta \) is in \( V_n \), then

\[ |S_n(\theta)| \leq c n (\log n)^{9/2} \left\{ \left( \frac{1}{q} + \frac{\varepsilon}{n} \right)^{1/2} + e^{-c \sqrt{\log n}} \right\}, \]

for \( \theta = \frac{a}{q} + \frac{\varepsilon}{q} \) with \( (a, q) = 1 \), \( 1 \leq a < q \), \( |\varepsilon| \leq 1 \).

Recall that for \( \theta \in V_n \)

\[ (\log n)^{3/2} \leq q \leq \frac{n}{(\log n)^{1/4}}. \]

Thus Vinogradov's estimate for \( |S_n(\theta)| \) gives 7) and the Goldbach-Vinogradov Theorem.

We begin by isolating one of Vinogradov's basic ideas. Namely in a double sum

\[ \sum_{n} \sum_{m} a_n b_m e^{2\pi i m \theta}, \]

there must be a lot of cancellation for most \( \theta \)'s, even if the \( a_n \) and \( b_m \) are quite irregular (like say \( a_n = \) number of divisors of \( n \) and \( b_m = \mu(m) \) where \( \mu \) is the Möbius function). To fix ideas consider

\[ s = \sum_{n=1}^{q} a_n \sum_{m=1}^{q} b_m e^{2\pi i m \frac{a}{q}}, \]

with \( (a, q) = 1 \). If we neglect the cancellation due to \( \exp(2\pi i m \frac{a}{q}) \),

we may trivially use Schwarz's inequality to obtain

\[ |s| \leq \sqrt{q} \sum_{n=1}^{q} |a_n| \sum_{m=1}^{q} |b_m| \leq q A B \]

where

\[ A = \left( \sum_{n=1}^{q} |a_n|^2 \right)^{1/2} \]

and

\[ B = \left( \sum_{m=1}^{q} |b_m|^2 \right)^{1/2}. \]

However, this estimate may be improved. Namely

\[ |s| \leq \sqrt{q} A B. \]

We now prove (10) (à la Vinogradov). Using Schwarz's inequality on the outer sum in (9), we see
Now since \((a,q) = 1\), one sees that the inner sum (which is the sum of a geometric progression) is \(q\) if \(m_1 = m_2\) and \(0\) otherwise. So we have

\[|s|^2 \leq q A^2 b^2,\]

which is (10).

To prove 8) of course we must also consider irrational \(\theta\)'s but this same slightly tricky use of Schwarz's inequality can still be used to obtain cancellation in that case.

To prove 8) we must use the well known Möbius function \(\mu\). We recall

\[\mu(1) = 1,\]
\[\mu(p_1, \ldots, p_r) = (-1)^r \quad \text{if} \quad p_i \neq p_j\]

and

\[\mu(n) = 0 \quad \text{if} \quad p^2 \text{ divides } n\]

for some prime \(p\).

We recall without proof the fundamental property of \(\mu\) that we need:

\[\text{II) } \sum_{d \mid a} \mu(d) = \begin{cases} 1 & \text{if } a = 1 \\ 0 & \text{if } a > 1 \end{cases}\]

Let \(R = \prod_{p < \sqrt{n}} p\). Then

\[S_n(\theta) = O(\sqrt{n}) + \sum_{\sqrt{n} \leq p \leq n} e^{2\pi i p \theta}\]

\[= O(\sqrt{n}) + \sum_{\sqrt{n} < m \leq n} e^{2\pi i m \theta}
\quad \text{if} \quad (R, m) = 1\]

\[= O(\sqrt{n}) + \sum_{1 \leq m \leq n} e^{2\pi i m \theta}
\quad \text{if} \quad (R, m) = 1\]

\[= O(\sqrt{n}) + \sum_{1 \leq m \leq n} e^{2\pi i m \theta} \sum_{d \mid (R, m)} \mu(d) e^{2\pi i d \theta}\]

\[= O(\sqrt{n}) + \sum_{1 \leq m \leq n} e^{2\pi i m \theta} \sum_{d \mid (R, m)} \mu(d) e^{2\pi i d \theta}\]
by II). 
\[(x,y) = \text{greatest common divisor of } x \text{ and } y\]. Interchanging the order of summation, one sees
\[
S_n(\theta) = O(\sqrt{n}) + \sum_{d \mid R} \mu(d) \sum_{d \mid m} \frac{1}{n} e^{2\pi i d \theta}.
\]

Now setting \( m = dr \), we have
\[
\text{II2)} \quad S_n(\theta) = O(\sqrt{n}) + \sum_{d \mid R} \mu(d) \sum_{d \mid n} \frac{1}{n} e^{2\pi i d r \theta}.
\]

Now at first glance things may appear very nice because the inner sum above is a geometric progression. However \( \mu(d) \) is not zero for more than \( O(n) \) values of \( d \), so we are very far from the proof. What we must do is replace the double sum in II2) by another double sum with shorter ranges of summation. However, we are willing to pay a price. Namely we do not need to have such regular coefficients as \( a_r = 1 \) (\( a_r \) is the coefficient of \( e^{2\pi i d r \theta} \) in the sum II2) if we use the idea of the proof of IO).

There are several methods of "shortening" the double sum at the price of introducing rough coefficients. We shall outline here the method given in Prachar Primzahlverteilung, where the complete details may be found.

Note: When we use the words relatively easy the reader should not try to stop and fill in the gaps as they are only really easy for people who are quite familiar with certain special methods of number theory. For complete details one should consult Prachar Primzahlverteilung.

Interchanging the order of summation in II2), we have
\[
\text{III)} \quad S_n(\theta) = O(\sqrt{n}) + \sum_{1 \leq r \leq n} \sum_{d \mid R} \mu(d) e^{2\pi i d r \theta} = L_n + F_n
\]

where
\[
L_n = \sum_{1 \leq r \leq \sqrt{\log n}} \sum_{d \mid R} \mu(d) e^{2\pi i d r \theta}
\]

and
\[
F_n = O(\sqrt{n}) + \sum_{r \leq n} \sum_{d \mid R} \mu(d) e^{2\pi i d r \theta}.
\]

Now \( F_n \) is relatively easy to dispose of because in this double sum above
\[
d \leq \frac{n}{r} \leq \frac{n}{\sqrt{\log n}}.
\]

This range of summation on \( d \) is sufficiently small that one may interchange the order of summation in \( F_n \) and use the fact that the sum on \( r \) is a geometric
progression. Thus we must consider $L_n$. Instead of considering $L_n$, we consider

$$G_n = \sum_{1 \leq r \leq \sqrt{\log n}} \sum_{d \mid r, 1 \leq d \leq n/r} u(d) e^{2\pi i dr}$$

d has at least one prime factor $\geq e^{2/\log n}$

Thus $G_n$ differs from $L_n$ in that now we are not summing over any $d$'s all of whose prime factors are less than $e^{2/\log n}$. A well known theorem of Rankin implies that there are so few such $d$'s that

$$\sum_{1 \leq r \leq \sqrt{\log n}} \sum_{d \mid r, 1 \leq d \leq n/r} 1 = O(n e^{-c/\log n}).$$

d has all prime factors $\leq e^{2/\log n}$

Thus it suffices to consider $G_n$. In $G_n$ we now write $d$ as $p^j$ where $p$ is a prime $e^{2/\log n} < p \leq \sqrt{n}$ (since $p \mid d$, $d \mid R$ and $R = \prod_{p \leq \sqrt{n}} p$).

Define

$$H_n = \sum_{1 \leq r \leq \sqrt{\log n}} \sum_{e^{2/\log n} \leq p \leq \sqrt{n}, j \mid R, 1 \leq j \leq n/p} u(j) e^{2\pi i jpr}$$

$H_n$ is not equal to $G_n$ because we have not taken into account the number of ways $d$ may be written as $p^j$. However, it is not too difficult to see that it suffices to consider $H_n$.

Note that in $H_n$ all the sums are much shorter than $n$,

$$j \leq \frac{n}{e^{2/\log n}} \leq \frac{n}{e^{2/\log n}} \quad \text{(since } p > e^{2/\log n})$$

But $H_n$ is a triple sum instead of a double sum.

Now to change this to a double sum we set $Z = pr$, and we have

$$H_n = \sum_{e^{2/\log n} \leq Z \leq \sqrt{n}, e^{2/\log n}} d_1(Z) \sum_{j \mid R, 1 \leq j \leq n/Z} u(j) e^{2\pi i jZ}$$

where $d_1(Z)$ is the number of ways of writing $Z = pr$. $d_1(Z)$ is of course very irregular; but $M(d_1(Z)) \leq d(Z)$ (the number of divisors of $Z$), and very good estimates for $\sum_{Z=1}^M |d(Z)|^2$ are known

$$\sum_{Z=1}^M |d(Z)|^2 = O(M (\log M)^3)$$

Notice in the last expression for $H_n$ both sums are much shorter than $n$. 

On Vinogradov's estimate

(\( j \leq \frac{n}{\sqrt{2 \log n}} \) since \( j \leq n/Z \) and \( Z \geq e^{2/\log n} \)). Thus we have achieved our objective: we have a double sum with shortened ranges of summation and of course have paid the stated price. If we now break the \( Z \)-sum in \( H_n \) into a most \( \log n \) dyadic blocks and use Schwarz's inequality as in the proof of 10), we may obtain 8).

At this point you basically understand the idea of the proof of 4). However, we shall proceed a little farther for completeness. (Note that the trivial estimate for \( H_n \) is

\[
|H_n| \leq n \sum_{\substack{Z \leq \sqrt{n} \log n \atop 1}} d(Z) / Z
\]

and this last quantity is \( > n \log n \)).

We divide \( H_n \) into dyadic blocks \( K(u) \) where

\[
K(u) = \sum_{u \leq Z < u'} d_1(Z) \cdot \sum_{j \in [R \frac{n}{Z}]} (j) e^{2\pi ijZ\theta}
\]

with \( u' \leq 2u \). We must consider at most \( \log n \) such blocks \( K(u) \). (A factor of \( \log n \) at this point makes little difference since one may just choose \( u \) a little larger in 5) to obtain 7).

Then

\[
|K(u)|^2 \leq \sum_{u \leq Z < u'} |d(Z)|^2 \sum_{u \leq Z < u'} \sum_{j \in [R \frac{n}{Z}]} \sum_{1 \leq j \leq n \atop j \in [Z]} \mu(j) e^{2\pi ijZ\theta} |^2
\]

\[
\leq c u(\log u)^3 \sum_{u \leq Z < u'} \sum_{j \in [R \frac{n}{Z}]} \sum_{1 \leq j \leq n \atop j \in [Z]} \mu(j) e^{2\pi ijZ\theta} \]

\[
= c u(\log u)^3 \sum_{1 \leq j \leq n \atop u \leq Z < u'} \sum_{1 \leq j \leq n \atop u \leq Z < u'} \min(u, \frac{1}{\sin(j_1-j_2)\theta}).
\]

If one now observes that for any integer \( k \), the fractional parts of the numbers 
\[ m\theta \]
are of the form

\[ \frac{s}{q} + \lambda_k + \frac{t}{2q} \]
with \( \lambda \) arbitrary and \( |e| \leq 1 \) and with each \( s \) arising from only one value of \( m \), the completion of the proof of 8) is then a matter of arithmetic.

To make the above observation note that

\[
m \theta = \lambda q \theta + (m - \lambda q) \theta = \lambda \theta + j \theta \quad \text{with} \quad -\frac{q}{2} < j < \frac{q}{2}.
\]

Hence we must just observe that

\[
j_1 \frac{a}{q} \not\equiv j_2 \frac{a}{q} \pmod{1} \quad \text{for} \quad j_1 \neq j_2.
\]

If \( j_1 a - j_2 a = q s \) for \( s \) an integer, the \( q|a(j_1 - j_2) \). But \( (a,q) = 1 \) and \( |j_1 - j_2| < q \) so this is impossible.

As our main objective was to indicate the proof of 8) (and hence 4), we shall give only a short summary of 3).

First we shall give the definition of \( u_n \)

\[
U_n = \bigcup_{q \leq (\log n)^a, \ (a,q) = 1, \ 0 < a < q} J_{a,q}
\]

\[
J_{a,q} = \{ \theta | \theta - \frac{a}{q} \leq \frac{(\log n)^a}{n} \}
\]

One sees easily that the intervals \( J_{a,q} \) are disjoint for \( n \) large.

Then \( V_n = [0,1] - U_n \). The theorem of Dirichlet on approximations of irrationals by rationals implies that each \( \theta \in V_n \) has the form

\[
\theta = \frac{a}{q} + \frac{e}{q} \frac{(\log n)^a}{n} = \frac{a}{q} + \frac{e'}{q}
\]

with \( |e'| |e| \leq 1 \), \( (\log n)^a \leq q \leq \frac{n}{(\log n)^a} \), and \( (a,q) = 1 \) as required above.

To prove 3) we need information on \( \pi(n,q;a) = \) the number of primes less than or equal to \( n \) which are congruent to \( a \) modulo \( q \).

The main tool for the estimate 3) is the following.

**THEOREM.** If \( (a,q) = 1 \)

\[
\pi(n,q,a) = \frac{1}{\phi(q)} \sum_{\nu=1}^{\lfloor \log n \rfloor} \frac{\nu}{\log \nu} + O(\sqrt{n} e^{-c/\sqrt{\log n}})
\]

uniformly for \( 1 \leq q \leq (\log n)^a \), where \( \phi(q) \) is the number of integers relatively prime to \( q \). Here \( c > 0 \).
On Vinogradov’s estimate

We shall not go into the proof of this difficult theorem [See Prachar]. (The original proof of the Goldbach-Vinogradov Theorem had much extra complication because the uniformity \( q \) was not as large as in the above theorem).

The first step in the above proof is the following.

**LEMMA.** For \( 0 \leq a < q \), \((a,q) = 1\), and \( 1 \leq q \leq (\log n)^{1/4} \),

\[ S_n(a_q) = \frac{u(q)}{\phi(q)} \int_1^n \frac{dt}{\log t} + O\left( n e^{-c \sqrt{\log n}} \right). \]

To prove (15) observe

\[ S_n(a_q) = \frac{1}{\phi(q)} \sum_{p \leq n} e^{2\pi i ap/q} = \frac{1}{\phi(q)} \sum_{p \mid q} e^{2\pi i ap} + \frac{1}{\phi(q)} \sum_{p \mid q} e^{2\pi i ap} \]

\[ = \frac{1}{\phi(q)} \sum_{\substack{p \mid m \leq n \cr m \mid q}} e^{2\pi i \frac{mp}{q}} \pi(n,q,m) + O(\log q). \]

Now one finishes the proof of (15) essentially by using (14). The next step is the following.

**LEMMA.** Let \( q \leq (\log n)^{1/4} \), \((a,q) = 1\), \( 0 \leq a < q \) and \( 0 \leq \beta \leq \frac{1}{2} \).

Then

\[ S_n(\frac{a+\beta}{q}) = \frac{u(q)}{\phi(q)} \sum_{1 \leq j \leq M} \frac{e^{2\pi i j \beta}}{\log j} + O\left( N(N|\beta| + 1)e^{-c \sqrt{\log n}} \right) \]

To prove (16) observe

\[ S_n(\frac{a+\beta}{q}) = \sum_{j=1}^n e^{2\pi i j \beta} [S_n(\frac{a}{q}) - S_{n-1}(\frac{a}{q})]. \]

One then sums by parts, uses (15) and completes the proof by another summation by parts.

The remainder of the proof of (3) is now relatively straightforward. One needs to substitute (16) into the integral for \( U_n \) and keep tract of the error terms.
