FUNCTIONAL INEQUALITIES FOR DISCRETE GRADIENTS
AND APPLICATION TO THE GEOMETRIC DISTRIBUTION

Aldéric Joulin¹ and Nicolas Privault¹

Abstract. We present several functional inequalities for finite difference gradients, such as a Cheeger inequality, Poincaré and (modified) logarithmic Sobolev inequalities, associated deviation estimates, and an exponential integrability property. In the particular case of the geometric distribution on \( \mathbb{N} \) we use an integration by parts formula to compute the optimal isoperimetric and Poincaré constants, and to obtain an improvement of our general logarithmic Sobolev inequality. By a limiting procedure we recover the corresponding inequalities for the exponential distribution. These results have applications to interacting spin systems under a geometric reference measure.

Mathematics Subject Classification. 60E07, 60E15, 60K35.

1. INTRODUCTION

Isoperimetry consists in finding sets of minimal surface among sets of a given volume, i.e. to search for optimal constants \( c \) in inequalities of the form

\[
 c I(\mu(A)) \leq \mu_s(A),
\]

where \( \mu_s \) and \( \mu \) are respectively surface and volume measures and \( I \) is a non-negative function on \([0, 1]\). Isoperimetric constants are linked, via co-area formulas, to functional inequalities such as Poincaré or logarithmic Sobolev inequalities. Discrete isoperimetry has been studied in various contexts, such as reversible Markov chains [10], [15], graph theory [1,18], statistical mechanics, cf. e.g. [9].

In this paper we consider the general discrete setting of a probability space \((E, \mathcal{E}, \mu)\), and a finite difference gradient \( d^+ \) defined as \( d^+ f = f \circ \tau - f \), where \( \tau : E \to E \) is an absolutely continuous mapping. Typically \( E = \mathbb{N} \) and \( d^+ f(k) = f(k+1) - f(k) \), in this case \( d^+ \) can be used to express the surface measure of a set as the expectation of a discrete gradient norm. However, \( E \) can be a more general, even uncountable, space. The abstract case of a metric space has been considered in [2, 5] for a gradient having the derivation property.

In this paper we consider the general discrete setting of a probability space \((E, \mathcal{E}, \mu)\), and a finite difference gradient \( d^+ \) defined as \( d^+ f = f \circ \tau - f \), where \( \tau : E \to E \) is an absolutely continuous mapping. Typically \( E = \mathbb{N} \) and \( d^+ f(k) = f(k+1) - f(k) \), in this case \( d^+ \) can be used to express the surface measure of a set as the expectation of a discrete gradient norm. However, \( E \) can be a more general, even uncountable, space. The abstract case of a metric space has been considered in [2, 5] for a gradient having the derivation property.

In Section 2 we recall a discrete generalization of Cheeger’s inequality [7], i.e. a lower bound on the spectral gap \( \lambda_\mu \) in terms of the isoperimetry constant \( h_\mu \), cf. [1,18]. When \( \mu \) is the geometric distribution \( \pi \) on \( \mathbb{N} \) with

© EDP Sciences, SMAI 2004
parameter $p \in (0,1)$ we show in Section 3.1 that $h_\pi = (1-p)/p$ and $\lambda_\pi = (1-\sqrt{p})/p$. The lower bound for $\lambda_\pi$ obtained from Cheeger’s inequality turns out to be optimal for the geometric distribution.

A measure $\mu$ is said to satisfy a logarithmic Sobolev inequality [12] with gradient $d$ and constant $C > 0$ when

$$\text{Ent}_\mu[f^2] \leq C\mathbb{E}_\mu[|df|^2], \quad (1.2)$$

where $\text{Ent}_\mu[f] = \mathbb{E}_\mu[f \log f] - \mathbb{E}_\mu[f] \log \mathbb{E}_\mu[f]$ denotes the entropy of $f$ under $\mu$. If the gradient $df$ has the derivation property, $(1.2)$ is equivalent to the following modified logarithmic Sobolev inequality

$$\text{Ent}_\mu[e^f] \leq \frac{C}{4}\mathbb{E}_\mu[|df|^2e^f]. \quad (1.3)$$

Such modified inequalities have been established for Poisson and Bernoulli measures on $\mathbb{N}$ in [3], using the finite difference gradient $d^+$. On the other hand, modified logarithmic Sobolev inequalities for the exponential distribution have been obtained in [2] under the additional hypothesis that $f$ is $c$-Lipschitz, i.e. $|df| \leq c$, when $d$ has the derivation property.

In Section 3.2 we adapt the method of [2] to the geometric distribution, which can be viewed as a discrete analog of the exponential distribution, since the inter-jump times of the Poisson (resp. binomial) process have exponential (resp. geometric) distributions. For this we use an integration by parts formula and replace the analog of the exponential distribution, since the inter-jump times of the Poisson (resp. binomial) process have been obtained in [2] under the additional hypothesis that $f$ is $c$-Lipschitz, i.e. $|df| \leq c$, when $d$ has the derivation property.

In Section 3.2 we adapt the method of [2] to the geometric distribution, which can be viewed as a discrete analog of the exponential distribution, since the inter-jump times of the Poisson (resp. binomial) process have exponential (resp. geometric) distributions. For this we use an integration by parts formula and replace the analog of the exponential distribution, since the inter-jump times of the Poisson (resp. binomial) process have been obtained in [2] under the additional hypothesis that $f$ is $c$-Lipschitz, i.e. $|df| \leq c$, when $d$ has the derivation property.

In Section 3.3, using the Herbst method we obtain a deviation result for the geometric distribution, which differs from the deviation inequality recently obtained in [13] from the covariance representation method for infinitely divisible distributions. Although the integral part $[X]$ of an exponential random variable with parameter $\lambda$ has a geometric law of parameter $e^{-\lambda}$, it does not seem possible to apply existing results on the exponential distribution [2] in our setting. For example, when $f : \mathbb{N} \to \mathbb{R}$ is Lipschitz, $f([X])$ is not the composition of a Lipschitz function with $X$. However, exponential random variables can be approximated in distribution by geometric random variables, and in this way we recover the functional inequalities proved in [2] for the exponential distribution.

In Section 4 we obtain a more general result, stating that any distribution $\mu$ that satisfies a Poincaré inequality with constant $\lambda_\mu$ for a finite difference gradient also satisfies a logarithmic Sobolev inequality of modified type for all function $f$ such that $|d^+f| \leq c$, which implies deviation bounds. In Section 4.2 we present an exponential integrability criterion.

Let us mention that the results of this paper can be applied to an interacting spin system under a geometric reference measure, for which a logarithmic Sobolev inequality and a deviation inequality can be proved, extending the results established in [9] under Poisson reference measures.

2. Notation and preliminaries

Given a probability space $(E, \mathcal{E}, \mu)$, let $\tau : E \to E$ denote a map absolutely continuous with respect to $\mu$. We denote by $d^+$ the finite difference gradient operator defined as

$$d^+f = f \circ \tau - f = \tau f - f,$$

where $f \circ \tau$ will be denoted by $\tau f$ for shortness of notation. If $x \in \mathbb{R}$ is such that $\mu(f \geq x) \geq 1/2$ and $\mu(f \leq x) \geq 1/2$, we say that $x$ is a median of $f$ under $\mu$, and write $m(f) = x$. We recall that for every median of $f$ we have

$$\mathbb{E}_\mu[|f - m(f)|] = \inf_{a \in \mathbb{R}} \mathbb{E}_\mu[|f - a|].$$
We will need the co-area formula

\[
\mathbb{E}_\mu [ |d^+ f|] = \int_{-\infty}^{+\infty} \mathbb{E}_\mu [ |d^+ 1_{\{f>t\}|} ] \ dt,
\]

which follows easily from the relations

\[
(b-a)^\pm = \int_{-\infty}^{\infty} (1_{\{a>t\}} - 1_{\{b>t\}})^\pm dt, \quad a, b \in \mathbb{R}.
\]

If \(E = \mathbb{N}\) then it is natural to consider the shift operator \(\tau f(k) = f(k+1), k \in \mathbb{N}\), and the associated gradient

\[
d^+ f(k) = f(k+1) - f(k), \quad k \in \mathbb{N}.
\]

(2.2)

Note that given \(A \subset \mathbb{N}\) we have

\[
\{ |d^+ 1_A| > 0 \} = \{ |d^+ 1_{A^c}| \geq 1 \} = \{ k \in A : k+1 \in A^c \} \cup \{ k \in A^c : k+1 \in A \},
\]

i.e. \(\{ |d^+ 1_A| > 0 \}\) represents a frontier \(\partial A\) of \(A\), and \(\mathbb{E}_\mu [ |d^+ 1_A| ]\) represents the measure of \(\partial A\). Throughout this paper, \(\mu\) denotes an arbitrary probability measure on \(E\), while \(\pi\) denotes the geometric distribution with parameter \(p \in (0,1)\) on \(E = \mathbb{N}\).

Let \(h_\mu\) denote the optimal constant in the inequality

\[
h_\mu \mathbb{E}_\mu [ |f - m(f)| ] \leq \mathbb{E}_\mu [ |d^+ f| ],
\]

i.e.

\[
h_\mu = \inf_{f \neq \text{const}} \frac{\mathbb{E}_\mu [ |d^+ f| ]}{\mathbb{E}_\mu [ |f - m(f)| ]}.
\]

Propositions 2.1 and 2.2 below are classical results in the settings of connected graphs and Markov chains under reversibility or ergodicity assumptions, see e.g. [1,15,18] and the references therein. The gradient used in our setting is different, but the proofs are similar and omitted here.

**Proposition 2.1.** We have

\[
h_\mu = \inf_{0 < \mu(A) \leq \frac{1}{2}} \frac{\mathbb{E}_\mu [ |d^+ 1_A| ]}{\mu(A)}.
\]

(4.4)

Let \(\lambda_\mu\) denote the optimal constant in the Poincaré inequality

\[
\lambda_\mu \text{Var}_\mu [f] \leq \mathbb{E}_\mu [ |d^+ f|^2 ],
\]

under \(\mu\), i.e.

\[
\lambda_\mu = \inf_{f \neq \text{const}} \frac{\mathbb{E}_\mu [ |d^+ f|^2 ]}{\text{Var}_\mu [f]}.
\]

The next result is a discrete generalization of Cheeger’s inequality [7], i.e. a lower bound on the spectral gap \(\lambda_\mu\) in terms of the isoperimetry constant \(h_\mu\), which shows that the strict positivity of \(h_\mu\) implies a Poincaré inequality.

**Proposition 2.2.** We have

\[
\left( \sqrt{1 + h_\mu} - 1 \right)^2 \leq \lambda_\mu \leq 2h_\mu.
\]

(6.6)

Note that (6.6) also yields an upper bound on \(h_\mu\) in terms of \(\lambda_\mu\):

\[
h_\mu \leq \lambda_\mu + 2 \sqrt{\lambda_\mu}.
\]

(7.7)
3. The geometric distribution

3.1. Optimal isoperimetric and Poincaré constants

We take \( E = \mathbb{N} \) and the gradient
\[
d^+ f(k) = f(k + 1) - f(k), \quad k \in \mathbb{N}.
\]
Under \( \pi \) the Laplacian \( \mathcal{L} = -d^+ d^- + \pi d^+ \) is given by
\[
-d^+ d^- f(k) = f(k + 1) - f(k) + \frac{1}{p} 1_{\{k \geq 1\}} (f(k - 1) - f(k)),
\]
i.e. \( \mathcal{L} = d^+ + \frac{1}{p} d^- \) with
\[
d^- f(k) = 1_{\{k \geq 1\}} (f(k - 1) - f(k)), \quad k \in \mathbb{N}.
\]
Poincaré inequalities for general discrete distributions have been proved in [4, 6, 8, 17]. Theorem 1.3 in [4] shows in particular that a discrete distribution \( \mu \) on \( \mathbb{N} \) satisfies (2.5) if and only if
\[
\mu(\{n\}) \geq c \mu([0, n]) (1 - \mu([0, n])), \quad n \geq 0,
\]
for some constant \( c > 0 \). It is easily seen that the geometric distribution \( \pi \) with parameter \( p \in (0, 1) \) given by:
\[
\pi(\{k\}) = p^k (1 - p), \quad k \in \mathbb{N},
\]
does satisfy this hypothesis. In this section we prove an isoperimetric inequality for the geometric distribution, which will imply a Poincaré inequality from Cheeger’s inequality (2.6). The proof relies as in [2] on an integration by parts formula under \( \pi \), stated here in the form of the next lemma, whose proof is immediate.

Lemma 3.1. Let \( f : \mathbb{N} \to \mathbb{R} \). We have
\[
\mathbb{E}_\pi[f] = f(0) + \frac{p}{1-p} \mathbb{E}_\pi[d^+ f]. \tag{3.1}
\]
In the next proposition we obtain the value of the optimal isoperimetric constant under the geometric distribution.

Proposition 3.2. Under the geometric distribution \( \pi \) we have
\[
h_\pi = \frac{1 - p}{p}. \tag{3.2}
\]
Proof. From the integration by parts formula (3.1) we have
\[
\mathbb{E}_\pi[|f - m(f)|] \leq \mathbb{E}_\pi[|f - f(0)|] = \frac{p}{1-p} \mathbb{E}_\pi[|d^+ f - f(0)|] \leq \frac{p}{1-p} \mathbb{E}_\pi[|d^+ f|],
\]
which shows \( h_\pi \geq (1 - p)/p \). On the other hand, letting \( f_n = 1_{[n+1, \infty)} \), \( n \in \mathbb{N} \), we have for any \( n \in \mathbb{N} \) such that \( \pi([n + 1, \infty)) \leq 1/2 \):
\[
h_\pi \leq \frac{\mathbb{E}_\pi[|d^+ f|]}{\mathbb{E}_\pi[|f - m(f)|]} = \frac{\pi(\{n\})}{\pi([n + 1, \infty))} = \frac{1-p}{p}. \tag*{□}
\]
In particular, the isoperimetric inequality becomes an inequality for functions of the form \( f_n = 1_{[n+1, \infty)} \), with \( n \geq -\log 2/\log p \).
Proposition 3.3. Under the geometric distribution $\pi$ we have

$$\lambda_\pi = \frac{(1 - \sqrt{p})^2}{p}. \quad (3.3)$$

Proof. Using Cheeger’s inequality (2.6) and Relation (3.2) we get 

$$\frac{(1 - \sqrt{p})^2}{p} \leq \lambda_\pi.$$ 

and taking the limit as $a \to 1/\sqrt{p}$ we get

$$\lambda_\pi \leq \frac{(1 - \sqrt{p})^2}{p}.$$ \hfill \Box

Here, the lower bound on $\lambda_\pi$ obtained from Cheeger’s inequality coincides with the optimal Poincaré constant.

Remark 3.4. The lower bound of $\lambda_\pi$ can be directly obtained from the integration by parts formula (3.1) under $\pi$.

Proof. Letting $g = f - f(0)$ we have $g(0) = 0$ and from (3.1) applied to $g^2$ we obtain:

$$\|g\|_2^2 = \frac{p}{1 - p} \mathbb{E}_\pi [d^+(g^2)]$$

$$= \frac{p}{1 - p} \mathbb{E}_\pi [gd^+g + \tau gd^+g]$$

$$\leq \frac{p}{1 - p} \left(\|g\|_2\|d^+g\|_2 + \|\tau d^+g\|_2\right)$$

$$= \frac{p}{1 - p} \left(\|g\|_2\|d^+f\|_2 + \frac{1}{\sqrt{p}}\|g\|_2\|d^+f\|_2\right)$$

$$= \frac{\sqrt{p}}{1 - \sqrt{p}}\|g\|_2\|d^+f\|_2,$$

hence

$$\|g\|_2 \leq \frac{\sqrt{p}}{1 - \sqrt{p}}\|d^+f\|_2,$$

and

$$\frac{(1 - \sqrt{p})^2}{p} \mathbb{E}[f] = \frac{(1 - \sqrt{p})^2}{p} \mathbb{E}[g] \leq \frac{(1 - \sqrt{p})^2}{p} \|g\|_2^2 \leq \mathbb{E}[d^+f]^2.$$ \hfill \Box

Using an approximation in distribution of exponential random variables by geometric random variables, we recover the Poincaré inequality of Lemma 2.1 in [2] for the exponential distribution with its optimal constant, cf. [11].

Proposition 3.5. Let $Y$ be an exponentially distributed random variable with parameter $-\log p$. We have

$$\mathbb{Var}[f(Y)] \leq \frac{4}{(\log p)^2} \mathbb{E}[|f'(Y)|^2]$$

for all Lipschitz function $f$ on $\mathbb{R}$.
Lemma 3.6. Let $X_\varepsilon$ be a geometric random variable with parameter $p^\varepsilon$. We have

$$\text{Var}[f(\varepsilon X_\varepsilon)] \leq \frac{\varepsilon^2 p^\varepsilon}{(1 - \sqrt{p^\varepsilon})^2} E\left[\left(\frac{f(\varepsilon X_\varepsilon + \varepsilon) - f(\varepsilon X_\varepsilon)}{\varepsilon}\right)^2\right].$$

It remains to let $\varepsilon$ go to 0 and to use the convergence of $\varepsilon X_\varepsilon$ in distribution to the exponential random variable $Y$ with parameter $-\log p$. \hfill \Box

Proof. From the integration by parts formula (3.1) we have

$$E[ f'(Y) - m(f(Y)) ] \leq \frac{1}{\log p} E \| f'(Y) \|.$$

The above constants $h = -\log p$ and $\lambda = (\log p)^2/4$ also satisfy the classical Cheeger inequality $\lambda \geq h^2/4$ which holds in the continuous case, cf. [7].

3.2. Modified logarithmic Sobolev inequality

In this section we obtain a modified logarithmic Sobolev inequality for the geometric distribution $\pi$ on $E = \mathbb{N}$, with $d^+ f(k) = f(k+1) - f(k), k \in \mathbb{N}$.

Lemma 3.6. Let $c < -\log p$ and let $f : \mathbb{N} \to \mathbb{R}$ be such that $d^+ f \leq c$ and $f(0) = 0$. We have

$$E_{\pi} [f^2 e^f] \leq \frac{p e^c}{(1 - p e^c)^2} E_{\pi} [e^f | d^+ f]^2]. \tag{3.4}$$

Proof. From the integration by parts formula (3.1) we have

$$E_{\pi} [f^2 e^f] = \frac{p}{1 - p} E_{\pi} [d^+ (f^2 e^f)]$$

$$= \frac{p}{1 - p} E_{\pi} [e^f \left( e^{d^+ f} \left( |d^+ f|^2 + 2f d^+ f \right) + f^2 (e^{d^+ f} - 1) \right)]$$

$$\leq \frac{p e^c}{1 - p} E_{\pi} [e^f \left( |d^+ f|^2 + 2f |d^+ f| \right)] + \frac{p (e^c - 1)}{1 - p} E_{\pi} [f^2 e^f],$$

hence

$$E_{\pi} [f^2 e^f] \leq \frac{p e^c}{1 - p e^c} E_{\pi} [e^f \left( |d^+ f|^2 + 2f |d^+ f| \right)]$$

$$\leq \frac{p e^c}{1 - p e^c} E_{\pi} [d^+ f]^2 e^f + 2 \frac{p e^c}{1 - p e^c} E_{\pi} \left[ f^2 e^f \right]^{1/2} E_{\pi} \left[ e^f |d^+ f|^2 \right]^{1/2},$$

which implies (3.4). \hfill \Box

Theorem 3.7. Let $0 < c < -\log p$ and let $f : \mathbb{N} \to \mathbb{R}$ such that $|d^+ f| \leq c$. We have

$$\text{Ent}_{\pi} [e^f] \leq \frac{p e^c}{(1 - p)(1 - \sqrt{p e^c})} E_{\pi} [d^+ f]^2 e^f]. \tag{3.5}$$

Proof. From the inequality $-u \ln u \leq 1 - u, u > 0$, we have:

$$\text{Ent}_{\pi} [e^f] = E_{\pi} [f e^f] - E_{\pi} [e^f] \ln E_{\pi} [e^f] \leq E_{\pi} [f e^f - e^f + 1]. \tag{3.6}$$
Let again $g = f - f(0),$ and let $h(v) = ve^v - e^v + 1.$ We have $h \circ g(0) = 0,$ and applying (3.1) to $h \circ g$ we get:

$$
\Ent_\pi [e^g] \leq \mathbb{E}_\pi [h \circ g] = \frac{p}{1-p} \mathbb{E}_\pi [d^+(h \circ g)] = \frac{p}{1-p} \mathbb{E}_\pi [h \circ (g + d^+ g) - h \circ g] \leq \frac{p}{1-p} \mathbb{E}_\pi [(|d^+ g|^2 + |g||d^+ g|) e^{g-d^+ g}],
$$

where the inequality

$$
h(a+b) - h(a) \leq (b^2 + |ab|)e^{a+b}, \quad a, b \in \mathbb{R},
$$

follows from the mean value theorem. From Lemma 3.6 and the Schwarz inequality we obtain:

$$
\Ent_\pi [e^f] = e^{f(0)} \Ent_\pi [e^g] \leq \frac{pe^{f(0)}}{1-p} \mathbb{E}_\pi \left[(|d^+ g|^2 + |g||d^+ g|) e^{g-d^+ g}\right] \leq \frac{pe^{f(0)}}{1-p} \left(\mathbb{E}_\pi [2e^g] + \mathbb{E}_\pi [g^2e^g]^{1/2} \mathbb{E}_\pi [e^{g-d^+ g}^{1/2}]\right) \leq \frac{pe^{f(0)}}{1-p} \left(1 + \frac{\sqrt{pe^{f(0)}}}{\sqrt{pe^{f(0)}}}\right) \mathbb{E}_\pi [(d^+ f)^2] e^g = \frac{pe^c}{(1-p)(1-\sqrt{pe^c})} \mathbb{E}_\pi [(d^+ f)^2].
$$

\hfill \Box

In higher dimensions we consider the multi-dimensional gradient defined as

$$
d^+_i f(k) = f(k + e_i) - f(k), \quad i = 1, \ldots, n,
$$

where $f$ is a function on $\mathbb{N}^n,$ $k = (k_1, \ldots, k_n) \in \mathbb{N}^n,$ $(e_1, \ldots, e_n)$ is the canonical basis of $\mathbb{R}^n,$ and the gradient norm

$$
||d^+_i f(k)||^2 = \sum_{i=1}^n |d^+_i f(k)|^2 = \sum_{i=1}^n |f(k+e_i) - f(k)|^2.
$$

From the tensorization property of entropy, (3.5) still holds with respect to $\pi^\otimes n$ in any finite dimension $n$:

$$
\Ent_{\pi^\otimes n} [e^f] \leq \frac{pe^c}{(1-p)(1-\sqrt{pe^c})} \mathbb{E}_{\pi^\otimes n} [(d^+ f)^2],
$$

provided $|d^+_i f| \leq c, i = 1, \ldots, n$ (we may also take $(1-p)^{-1}(1-\sqrt{pe^c})^{-1}$ as logarithmic Sobolev constant). Using an approximation in law of the exponential distribution by renormalized geometric random variables, we recover the logarithmic Sobolev inequality of Proposition 2.2 in [2].

**Proposition 3.8.** Let $Y$ be an exponentially distributed random variable with parameter $-\log p.$ We have

$$
\mathbb{E}_{\pi^\otimes n} [e^f(Y)] \leq \frac{2}{(\log p)(\log(p) + c)} \mathbb{E}_{\pi^\otimes n} [e^{f(Y)} | f'(Y)|^2],
$$

for every $c$-Lipschitz function $f$ on $\mathbb{R}.$
Proof. We apply (3.5) to $X_{\varepsilon}$, and get for every $c$-Lipschitz function $f$:

$$\text{Ent}_\pi \left[ e^{f(X_{\varepsilon})} \right] \leq \frac{2e^{p\sigma_c}}{(1-p)(1-\sqrt{p\sigma_c})} \mathbb{E}_\pi \left[ e^{f(X_{\varepsilon})} \left( \frac{f(\varepsilon X_{\varepsilon}) + \varepsilon - f(\varepsilon X_{\varepsilon})}{\varepsilon} \right)^2 \right].$$

It remains to let $\varepsilon$ go to 0. \hfill \Box

3.3. Deviation inequality

In this section we prove a deviation inequality for functions of several variables under $\pi^\otimes n$ using the Herbst method and the above modified logarithmic Sobolev inequality.

**Corollary 3.9.** Let $0 < c < -\log p$ and let $f$ such that $|d_i^+ f| \leq \beta$, $i = 1, \ldots, n$, and $\|d^+ f\|_2^2 \leq \alpha^2$ for some $\alpha, \beta > 0$. Then for all $r > 0$,

$$\pi^\otimes n (f - \mathbb{E}_x [f] \geq r) \leq \exp \left( -\min \left( \frac{\alpha^2 r^2}{4\alpha^2 \beta^2}, \frac{\beta c}{\alpha^2 a_{p,c}} \right) \right),$$

where

$$a_{p,c} = \frac{p\sigma_c}{(1-p)(1-\sqrt{p\sigma_c})}$$

denotes the logarithmic Sobolev constant in (3.5).

**Proof.** Assume that $|d_i^+ f| \leq \varepsilon$, $i = 1, \ldots, n$. For $0 < t \leq 1$, let

$$H(t) = \frac{1}{t} \log \mathbb{E}_x [e^{t f}]$$

with $H(0^+) = \mathbb{E}_x [f]$. In order for $H(t)$ to be finite we may first assume that $f$ is bounded, and then remove this assumption via a limiting argument once (3.9) is obtained. From (3.5) we have:

$$H'(t) = \frac{1}{t^2} \frac{\text{Ent}_{\pi^\otimes n} [e^{t f}]}{\mathbb{E}_x [e^{t f}]} \leq \alpha^2 a_{p,c},$$

so that

$$H(t) \leq \mathbb{E}_x [f] + ta^2 a_{p,c},$$

hence

$$\mathbb{E}_x [e^{t f}] \leq \exp \left( t\mathbb{E}_x [f] + t^2 \alpha^2 a_{p,c} \right), \quad 0 < t \leq 1.$$  

(3.10)

Finally, using Chebychev’s inequality we obtain from (3.10):

$$\pi^\otimes n (f - \mathbb{E}_x [f] \geq r) \leq \inf_{t \in (0,1]} e^{-rt} \mathbb{E}_x [\exp(t(f - \mathbb{E}_x [f]))]$$

$$\leq \exp \left( \inf_{t \in (0,1]} (-tr + t^2 \alpha^2 a_{p,c}) \right)$$

$$= \exp \left( -\min \left( \frac{r^2}{4\alpha^2 a_{p,c}}, r - \alpha^2 a_{p,c} \right) \right), \quad r > 0,$$

where we used the fact (see e.g. Cor. 2.11 in [16]) that the above minimum is attained at $t = \min(1, \frac{r}{2\alpha^2 a_{p,c}})$. Assume now that $f$ satisfies $|d_i^+ f| \leq \beta$, $i = 1, \ldots, n$, for some $\beta > 0$. Then $c f / \beta$ satisfies the above hypothesis and we get

$$\pi^\otimes n (f - \mathbb{E}_x [f] \geq r) \leq \exp \left( -\min \left( \frac{c^2 r^2}{4\alpha^2 \beta^2}, \frac{rc}{\beta} - \alpha^2 a_{p,c} \right) \right).$$
Corollary 3.9 implies in particular $\mathbb{E}_\pi[e^{\phi f}] < \infty$ for all $\alpha < c/\beta$ and $|d^+f| < c$. The condition $c < -\log p$ in Corollary 3.9 is necessary, since $f(k) = ck$ is not exponentially integrable under the geometric distribution $\pi$ when $c \geq -\log p$. When $n = 1$, $\alpha = \beta$ and $r \geq 2c/\alpha_{p,c}$, we have

$$\pi(f - \mathbb{E}_\pi[f] \geq r) \leq \exp\left(-\frac{rc}{\beta} + c^2 \alpha_{p,c}\right) \leq \exp\left(-\frac{rc}{2\beta}\right),$$

(3.11)

and if $r \leq 2c/\alpha_{p,c}$:

$$\pi(f - \mathbb{E}_\pi[f] \geq r) \leq \exp\left(-\frac{r^2}{4\alpha_{p,c}\beta^2}\right).$$

These bounds can be compared to the result of [13]:

$$\pi(f - \mathbb{E}_\pi[f] \geq r) \leq \left(1 + (1-p)\frac{r}{\beta}\right) \exp\left(-\left(\frac{r}{\beta} + \frac{p}{1-p}\right) \log \frac{p + p(1-p)r/\beta}{p + (1-p)r/\beta}\right),$$

$r > 0$, and to the exact deviation

$$\pi(X - \mathbb{E}_\pi[X] \geq r) = \exp\left(\left[r + \frac{1}{1-p}\right] - 1\right) \log p$$

for $X$ a geometric random variable with parameter $p$, where $[x]$ denotes the integral part of $x \in \mathbb{R}$. Applying the inequality (3.9) to $-f$, we obtain the concentration inequality

$$\pi^\otimes n(||f - \mathbb{E}_\pi[f]| \geq r) \leq 2 \exp\left(-\min\left(\frac{r^2}{4c}\alpha_{p,c}\beta^2\right)\right).$$

(3.12)

Consider the negative binomial distribution $\nu$ with parameters $n \geq 1$ and $p \in (0,1)$, defined as

$$\nu(\{k\}) = \binom{n + k - 1}{n - 1} (1-p)^n p^k, \quad k \in \mathbb{N}.$$  

Negative binomial random variables can be constructed as sums of $n$ independent and identically distributed geometric variables with parameter $p$. Therefore, if we apply (3.9) to

$$f(k_1, \ldots, k_n) = \phi(k_1 + \cdots + k_n), \quad (k_1, \ldots, k_n) \in \mathbb{N}^n,$$

we obtain the modified logarithmic Sobolev inequality

$$\text{Ent}_{\nu} [e^\phi] \leq n \alpha_{p,c} \mathbb{E}_{\nu} [d^+\phi^2 e^\phi],$$

and the deviation inequality

$$\nu(\phi - \mathbb{E}_\nu[\phi] \geq r) \leq \exp\left(-\min\left(\frac{r^2}{4n\alpha_{p,c}\beta^2}\right)\right),$$

where $\phi : \mathbb{N} \to \mathbb{R}$ satisfies $|d^+\phi| \leq \beta$, for the negative binomial distribution $\mu$. Similar results can be obtained for the tensor product of negative binomial laws with parameters $n_1, \ldots, n_d$, namely by replacing $\alpha_{p,c}$ with $(n_1 + \cdots + n_d)\alpha_{p,c}$ in (3.5) and (3.9).

Geometric and negative binomial random variables can be constructed as hitting times of the binomial process, thus they can be viewed as random variables on Bernoulli space. However, applying to them the Poincaré and logarithmic Sobolev inequalities on Bernoulli space (see e.g. [14]) yields results that are weaker than the above inequalities.
4. THE ABSTRACT CASE

In this section, we turn again to the general case of a probability space \((E, \mathcal{E}, \mu)\) with an absolutely continuous mapping \(\tau : E \to E\). We show that modified logarithmic Sobolev and deviation inequalities hold for every measure \(\mu\) on \(E\) which satisfies a Poincaré inequality

\[
\lambda_\mu \text{Var}_\mu[f] \leq \mathbb{E}_\mu \left[ |d^+ f|^2 \right]
\]

(4.1)

with respect to \(d^+, \) i.e. for every measure \(\mu\) such that \(\lambda_\mu > 0\). The application of the general results of this section to the geometric distribution using the spectral gap value (3.3) of \(\lambda_x\) allow to recover the inequalities of Section 3.2. However, explicit calculations show that the results are recovered with worse constants for all \(p \in (0, e^{-c})\), especially as \(p\) approaches \(e^{-c}\).

4.1. Logarithmic Sobolev inequality and deviation inequality

Before turning to the main result of this section, we need the two following propositions whose proofs are adapted from [2], replacing the chain rule of derivation by the mean value theorem, and postponed to the end of this section. The next proposition is a generalization of Lemma 3.6.

**Proposition 4.1.** Let \(c > 0\). For any \(f\) on \(E\) such that \(|d^+ f| \leq c\) with \(c^2 e^c \leq 4\lambda_\mu\) and \(\mathbb{E}_\mu[f] = 0\),

\[
\mathbb{E}_\mu\left[ f^2 e^f \right] \leq \alpha_{\mu,c} \mathbb{E}_\mu \left[ |d^+ f|^2 e^f \right],
\]

(4.2)

where \(\alpha_{\mu,c} = e^{c(2+\sqrt{\lambda_\mu}+c)^2}/\lambda_\mu(2\sqrt{\lambda_\mu-c^2/2})^2\).

The next statement is a modification of Proposition 3.4 in [2].

**Proposition 4.2.** For any \(f : E \to \mathbb{R}\) such that \(\mathbb{E}_\mu[f] = 0\) and \(|d^+ f| \leq c\) we have

\[
\mathbb{E}_\mu\left[ f^2 + \tau f^2 \right] \leq e^{c(1+\sqrt{\lambda_\mu})} \mathbb{E}_\mu\left[ (f^2 + \tau f^2) e^{-|f|} \right].
\]

(4.3)

The following is a modified logarithmic Sobolev inequality which holds whenever \(\lambda_\mu > 0\).

**Theorem 4.3.** Assume that \(f : E \to \mathbb{R}\) satisfies \(|d^+ f| \leq c\) with \(c^2 e^c \leq 4\lambda_\mu\),

\[
\text{Ent}_\mu\left[ e^f \right] \leq \frac{1}{2} e^{c(1+\sqrt{\lambda_\mu})} \mathbb{E}_\mu\left[ (\alpha_{\mu,c} |d^+ f|^2 + 2e^{2c} \alpha_{\mu,c} |d^+ f|^2 + 2e^{2c} \|d^+ f\|_{L_2(\mu)}^2) e^f \right].
\]

(4.4)

**Proof.** It suffices to suppose \(\mathbb{E}_\mu[f] = 0\). From the inequality \(x \log x \geq x - 1, \) \(x > 0\), we have

\[
\text{Ent}_\mu\left[ e^f \right] \leq \mathbb{E}_\mu\left[ f e^f - e^f + 1 \right] = \mathbb{E}_\mu\left[ \int_{0}^{1} t f^2 e^f \, dt \right],
\]

hence

\[
\text{Ent}_\mu\left[ e^f \right] \leq \int_{0}^{1} t \varphi(t) \, dt,
\]

where \(\varphi(t) = \mathbb{E}_\mu\left[ (f^2 + \tau f^2) e^{tf} \right], 0 \leq t \leq 1,\) is a convex function which satisfies \(\varphi(t) \leq \max(\varphi(0), \varphi(1)), \) \(0 \leq t \leq 1.\) Moreover, by Proposition 4.2 we have

\[
\varphi(0) \leq e^{c(1+\sqrt{\lambda_\mu})} \varphi(1),
\]
Corollary 4.4. provided

Hence

\[ \text{Ent}_\mu [e^f] \leq \int_0^1 te^{(1+\sqrt{\frac{1}{\alpha}})} \varphi(t) dt = \frac{1}{2} e^{(1+\sqrt{\frac{1}{\alpha}})} E_\mu \left[ (f^2 + \tau f^2) e^f \right]. \]

Since \( |d^+(\tau f - E_\mu[\tau f])| = |d^+\tau f| \leq c \), Proposition 4.1 applied to \( \tau f - E_\mu[\tau f] \) implies:

\[
\begin{align*}
E_\mu \left[ \tau f^2 e^f \right] &\leq e^c E_\mu \left[ \tau f^2 e^f \right] \\
&\leq 2e^{c+\xi E_\mu[\tau f]} E_\mu \left[ (\tau f - E_\mu[\tau f])^2 e^{f - E_\mu[\tau f]} \right] + 2e^c (E_\mu[\tau f])^2 E_\mu \left[ e^{f} \right] \\
&\leq 2e^c \alpha_{\mu,c} E_\mu \left[ |d^+\tau f|^2 e^{f} \right] + 2e^{2c} (E_\mu[\tau f])^2 E_\mu \left[ e^{f} \right] \\
&= 2e^{2c} \alpha_{\mu,c} E_\mu \left[ |d^+\tau f|^2 e^{f} \right] + 2e^{2c} (E_\mu[d^+f])^2 E_\mu \left[ e^{f} \right].
\end{align*}
\]

Hence

\[
\text{Ent}_\mu [e^f] \leq \frac{1}{2} e^{c(1+\sqrt{\frac{1}{\alpha}})} E_\mu \left[ (f^2 + \tau f^2) e^f \right] \\
\leq \frac{1}{2} e^{c(1+\sqrt{\frac{1}{\alpha}})} E_\mu \left[ (\alpha_{\mu,c}|d^+f|^2 + 2e^{2\alpha_{\mu,c}}|d^+\tau f|^2 + 2e^{2\alpha_{\mu,c}}|d^+f|^2) e^f \right].
\]

We also have

\[
\text{Ent}_\mu [e^f] \leq \frac{1}{2} e^{c(1+\sqrt{\frac{1}{\alpha}})} (\alpha_{\mu,c} + 2e^{2c}) |d^+f|_\infty E_\mu [e^f], \quad |d^+f| \leq c.
\]

By tensorization, Theorem 4.3 implies in higher dimensions

\[
\text{Ent}_{\mu^{\otimes n}} [e^f] \leq \frac{1}{2} e^{c(1+\sqrt{\frac{1}{\alpha}})} E_{\mu^{\otimes n}} \left[ (\alpha_{\mu,c} |d^+f|_\infty^2 + 2e^{2\alpha_{\mu,c}} |d^+\tau f|_\infty^2 + 2e^{2\alpha_{\mu,c}} |d^+f|_\infty^2 L_{2}(E^n \otimes \mathbb{R}^n)) e^f \right] \\
\leq m_{\mu,c} |d^+f|_\infty^2 L_{2}(E^n \otimes \mathbb{R}^n) E_{\mu^{\otimes n}} [e^f],
\]

where

\[
m_{\mu,c} = \frac{1}{2} e^{c(1+\sqrt{\frac{1}{\alpha}})} (\alpha_{\mu,c} + 2e^{2c})
\]

and

\[
d^+ f(x_1, \ldots, x_n) = \tau_i f(x_1, \ldots, x_n) - f(x_1, \ldots, x_n),
\]

\[
= f(x_1, \ldots, x_{i-1}, \tau_i(x_i), x_{i+1}, \ldots, x_n) - f(x_1, \ldots, x_n),
\]

provided \( |d^+_i f| \leq c, i = 1, \ldots, n \). As in Section 3.2 we obtain as a corollary a deviation inequality for the product measure \( \mu^{\otimes n} \) on \( E^n \):

**Corollary 4.4.** Assume that \( \mu \) satisfies a Poincaré inequality (4.1). Let \( c > 0 \) such that \( c^2 e^c \leq 4\lambda_\mu \), and let \( f \) such that \( |d^+_i f| \leq \beta, i = 1, \ldots, d \), and \( ||d^+ f||^2 \leq \alpha^2 \), for some \( \alpha, \beta > 0 \). Then for all \( r > 0 \),

\[
\mu^{\otimes n} \left( f - \mathbb{E}_{\mu^{\otimes n}}[f] \geq r \right) \leq \exp \left( - \min \left( \frac{c^2 r^2}{4m_{\mu,c} \alpha^2 / \beta^2}, \frac{rc}{\beta} - \alpha^2 m_{\mu,c} \right) \right).
\]

Next we provide the proofs of Propositions 4.1 and 4.2.
Proof of Proposition 4.1. Set $a^2 = \mathbb{E}_\mu [f^2/e^f]$ and $b^2 = \mathbb{E}_\mu [d^+ f^2/e^f]$. Since $\mathbb{E}_\mu[f] = 0$, the Poincaré inequality (4.1) implies

$$
\lambda^2 \mathbb{E}_\mu [f e^{f/2}]^2 \leq \mathbb{E}_\mu [d^+ f^2] \mathbb{E}_\mu \left[ d^+ \left( e^{f/2} \right)^2 \right] \\
\leq \frac{1}{4} \mathbb{E}_\mu [d^+ f^2] \mathbb{E}_\mu \left[ d^+ f^2 e^{f+|d^+f|} \right] \\
\leq \frac{1}{4} e^c e^2 b^2. \tag{4.6}
$$

Applying again the Poincaré inequality to $f e^{f/2}$ and using the mean value theorem we have

$$
\lambda \mathbb{E} \left[ |f| e^{f/2} \right] \leq \mathbb{E} \left[ |d^+ f| \left( 1 + \frac{|f| + |d^+ f|}{2} \right)^2 e^{f+|d^+ f|} \right] \\
\leq e^c \mathbb{E} \left[ |d^+ f| \left( 1 + \frac{|f| + c}{2} \right)^2 e^f \right] \\
\leq \left( 1 + \frac{c}{2} \right)^2 e^c b^2 + \frac{c^2 e^c b^2}{4} + \left( 1 + \frac{c}{2} \right) e^c \mathbb{E}_\mu [d^+ f^2 |f| e^f] \\
\leq \left( 1 + \frac{c}{2} \right)^2 e^c b^2 + \frac{c^2 e^c b^2}{4} + \left( 1 + \frac{c}{2} \right) e^c abc \\
\leq e^c \left( \left( 1 + \frac{c}{2} \right) b + \frac{ac}{2} \right)^2.
$$

Hence

$$a^2 = \mathbb{E}_\mu [f e^{f/2}]^2 + \text{Var} \left[ f e^{f/2} \right] \leq e^c e^2 b^2 + e^c \left( \left( 1 + \frac{c}{2} \right) b + \frac{ac}{2} \right)^2,$$

which leads to

$$a \leq \frac{e^{c/2} (2 + c) \sqrt{\lambda} + c}{\sqrt{\lambda} \mu (2 \sqrt{\lambda} - ce^{c/2})},$$

from which the conclusion follows. \(\square\)

With $\lambda = (1 - \sqrt{p})^2/\rho$, the condition $c^2 e^c \leq 4 \lambda$ implies $c < -\log p$, $p \in (0,1)$, hence Theorem 4.3 and Corollary 4.4 are weaker than Theorem 3.7 and Corollary 3.9 respectively, when $\mu = \pi$ is the geometric distribution.

Proof of Proposition 4.2. We have from the Poincaré inequality (4.1):

$$
\lambda \mathbb{E}_\mu \left[ f^4 \right] = \lambda \mathbb{E}_\mu \left[ f^2 \right] + \lambda \mathbb{E}_\mu \left( \mathbb{E}_\mu \left[ f^2 \right]^2 \right) \\
\leq \mathbb{E}_\mu \left[ d^+ f^2 \right] + \lambda \mathbb{E}_\mu \left( \mathbb{E}_\mu \left[ f^2 \right]^2 \right) \\
= \mathbb{E}_\mu \left[ d^+ f^2 \right] + \lambda \mathbb{E}_\mu \left( \mathbb{E}_\mu \left[ f^2 \right]^2 \right) \\
\leq 2 e^2 \mathbb{E}_\mu \left[ f^2 + \tau f^2 \right] + \mathbb{E}_\mu \left[ d^+ f^2 \right] \mathbb{E}_\mu \left[ f^2 \right] \\
\leq 3 e^2 \mathbb{E}_\mu \left[ f^2 \right] + 2 e^2 \mathbb{E}_\mu \left[ \tau f^2 \right].
$$

Hence for all $u > 0$,

$$\mathbb{E}_\mu \left[ |f|^3 \right] \leq \frac{u}{2} \mathbb{E}_\mu \left[ f^2 \right] + \frac{1}{2u} \mathbb{E}_\mu \left[ f^4 \right] \leq c_1 \mathbb{E}_\mu \left[ f^2 \right] + c_2 \mathbb{E}_\mu \left[ \tau f^2 \right] \tag{4.7}$$
with $c_1 = \frac{3e^2}{2u\lambda_\mu} + \frac{u}{2}$ and $c_2 = \frac{e^2}{u\lambda_\mu}$. Let us consider the probability measure

$$dp = \frac{c_1 f^2 + c_2 \tau f^2}{c_1 E_\mu [f^2] + c_2 E_\mu [\tau f^2]} d\mu.$$  

By Jensen’s inequality,

$$E_\mu \left[ (c_1 f^2 + c_2 \tau f^2) e^{-1/f} \right] = E_\mu [e^{-1/f}] E_\mu [c_1 f^2 + c_2 \tau f^2] \geq e^{-E_\mu [1/f]} E_\mu [c_1 f^2 + c_2 \tau f^2].$$

From the inequality $ab \leq a^3 + |b - a|(a^2 + b^2)$, $a, b \geq 0$, we have

$$|f| \tau f^2 \leq |f|^3 + c (f^2 + \tau f^2),$$

hence

$$E_\mu [|f|] E_\mu [c_1 f^2 + c_2 \tau f^2] \leq E_\mu [c_1 |f|^3 + c_2 |f| \tau f^2] \leq E_\mu [(c_1 + c_2) |f|^3 + c_2 |f|^2 (f^2 + \tau f^2)] \leq (c_1 + c_2) E_\mu [c_1 f^2 + c_2 \tau f^2] + c_2 E_\mu [f^2 + \tau f^2].$$

where we used the fact that $c_2 \leq c_1$. Therefore,

$$E_\mu [|f|] \leq c_1 + c_2 + c = \frac{5c^2 + uw^2\lambda_\mu}{2u\lambda_\mu} + c.$$

Optimizing in $u$ we obtain for $u = c\sqrt{\frac{5}{\lambda_\mu}}$:

$$E_\mu [|f|] \leq c \left(1 + \sqrt{\frac{5}{\lambda_\mu}}\right).$$

As in [2] and references therein, we can obtain the following bound.

**Proposition 4.5.** Let $A, B$ be disjoint subsets of $E$. We have

$$\mu(A) \mu(B) \leq 3 \exp \left(-\sqrt{\lambda_\mu e^{-\gamma_1/2}d(A, B)}\right),$$

(4.8)

with $\gamma_1^2 e^{\gamma_1} = 2\lambda_\mu$.

**Proof.** From the Poincaré inequality on $(E^2, \mu\otimes\mu)$ we have:

$$\lambda_\mu E_{\mu \otimes \mu} [f^2] \leq E_{\mu \otimes \mu} [d_1^+ f^2 + d_2^+ f^2],$$

provided $E_{\mu \otimes \mu} [f] = 0$. Applying this inequality to $f(x, y) = \sinh(tg(x, y)/2)$, $0 \leq t < \gamma_1$ with $g(x, y) = h(x) - h(y)$ and $|dh| \leq 1$, and using the bound

$$|\sinh(x + y) - \sinh(x)| \leq |y| e^{\gamma_1} \cosh x, \quad x, y \in \mathbb{R},$$

we get

$$\mu(A) \mu(B) \leq 3 \exp \left(-\sqrt{\lambda_\mu e^{-\gamma_1/2}d(A, B)}\right).$$
we have:

\[ \lambda_\mu E_{\mu \otimes 2}[\cosh^2(tg/2)] - \lambda_\mu = \lambda_\mu E_{\mu \otimes 2}[\sinh^2(tg/2)] \]

\[ \leq \frac{t^2}{4} E_{\mu \otimes 2} \left[ \left( |d_1^+ g|^2 e^{i|d_1^+ g|} + |d_2^+ g|^2 e^{i|d_2^+ g|} \cosh^2(tg/2) \right) \right] \]

\[ \leq \frac{t^2}{2} e^{\gamma_1} E_{\mu \otimes 2} \left[ \cosh^2(tg/2) \right]. \]

Hence

\[ E_{\mu \otimes 2}[\cosh^2(tg/2)] = \frac{1}{2} (E_{\mu \otimes 2}[e^{tg}] + 1) \leq \frac{2\lambda_\mu}{2\lambda_\mu - t^2 e^{\gamma_1}}. \]

and for all \( t < \gamma_1 \), if \( h(x) = d(x, B) \) then

\[ e^{td(A, B)} \mu(A) \mu(B) \leq E_{\mu \otimes 2}[1_{A \times B} e^{tg}] \leq E_{\mu \otimes 2}[e^{tg}] \leq \frac{2\lambda_\mu + t^2 e^{\gamma_1}}{2\lambda_\mu - t^2 e^{\gamma_1}} \]

and it remains to take \( t = \sqrt{\lambda_\mu} e^{-\gamma_1/2} \).

\[ \square \]

**4.2. Exponential integrability**

The Herbst method used in the preceding sections relies on exponential integrability. Following [2], we obtain a bound of the Laplace transform with respect to any measure \( \mu \) on \( E \), provided it follows a Poincaré inequality (4.1).

**Proposition 4.6.** Let \( f : E \to \mathbb{R} \) be such that \( E_{\mu}[f] = 0 \), with \( |d^+ f| \leq \beta \) for some \( \beta > 0 \), and let \( c \) such that \( e^c e^c \leq 4\lambda_\mu \). Then, for every \( 0 \leq t < c/\beta \) we have

\[ E_{\mu}[e^{tf}] \leq \frac{2\sqrt{\lambda_\mu}}{2\sqrt{\lambda_\mu} - t\beta e^{c/2}}. \]  

(4.9)

**Proof.** We adapt the proof of Proposition 4.1 in [2]. It is sufficient to assume \( \beta = 1 \). We have

\[ |d^+ e^{tf}(x)| = |e^{\pi f(x)} - e^{\pi f(x)}| \]

\[ = t \left| \int_{f(x)} \frac{f'(\tau(x))}{\sqrt{f(x)}} d\tau(x) \right| \]

\[ \leq t \left| e^{\pi f(x)} + |d^+ f(x)| |d^+ f(x)| \right| \]

\[ \leq t \left| e^{\pi f(x)} + |d^+ f(x)| |d^+ f(x)| \right| \]

and applying (4.1) to \( e^{tf} \) we get, with \( u(t) = E_{\mu}[e^{tf}] \):

\[ \lambda_\mu (u(t) - u(t/2)^2) \leq e^c \frac{t^2}{4} u(t), \]

i.e.

\[ u(t) \leq \frac{4\lambda_\mu}{4\lambda_\mu - t^2 e^c} u(t/2)^2. \]
Applying the same inequality for \( t/2 \) and iterating, we have

\[
u(t) \leq \prod_{k=0}^{\infty} \left( \frac{4\lambda_{\mu}}{4\lambda_{\mu} - e^{c}t^2/4k} \right)^{2^k} \leq \frac{4\lambda_{\mu}}{4\lambda_{\mu} - e^{c}t^2} V(t),
\]

with

\[
V(t) = \prod_{k=1}^{\infty} \left( \frac{4\lambda_{\mu}}{4\lambda_{\mu} - e^{c}t^2/4k} \right)^{2^k},
\]

where the product converges whenever \( t < c \). It can be shown as in [2] that \( \sqrt{V} \) is convex. Moreover \( V(0) = 1 \) and \( V \left( 2\sqrt{\frac{\lambda_{\mu}}{e^{c}2}} \right) \leq 4 \), hence

\[
\sqrt{V(t)} \leq 2\sqrt{\frac{\lambda_{\mu} + te^{c}/2}{2\sqrt{\lambda_{\mu}}}}.
\]

It is easily checked that the assumption of Corollary 4.4 is consistent with that of Proposition 4.6.

Acknowledgements. We thank Djalil Chafai and Christian Houdré for useful discussions.
