## by Enrico BOMBIERI

I. Let $C / k, k=\mathbb{F}_{q}$, be a projective non-singular curve of genus $g$, over a finite field $k$ of characteristic $p$, with $q$ elements. Let $k_{r}=\mathbb{F}{ }_{q}$ and let $\nu_{r}(C)$ be the number of $k_{r}$-rational points of the curve $C$. It is well-known that

$$
\begin{equation*}
v_{r}(c)=q^{r}-\sum_{1}^{2 g} w_{i}^{r}+1 \tag{1}
\end{equation*}
$$

where the $\omega_{i}$ are algebraic integers independent of $r$, such that
(2)
(3)

$$
\begin{array}{ll}
w_{i} w_{2 g-i}=q & \text { (functional equation) } \\
\left|w_{i}\right|=q^{\frac{1}{2}} & \text { (Riemann hypothesis). }
\end{array}
$$

Of these results, (1) and (2) are easy consequences of the Riemann-Roch theorem on C , while (3) lies deeper. The first general proof of (3) was obtained by Weil [3], as a consequence of the inequality

$$
\begin{equation*}
\left|v_{r}(c)-\left(q^{r}+1\right)\right| \leq 2 g q^{r / 2} \tag{4}
\end{equation*}
$$

Until recently, all existing proofs of (3) followed Weil's method, either using the Jacobian variety of $C$ or the Riemann-Roch theorem on $C \times C$. In this talk I want to explain a new approach to (3) invented by S. A. Stepanov [2]. Stepanov himself proved (3) in special cases, e.g. if $C$ was a Kummer or on Artin-Schreier covering of $\mathbb{P}^{1}$, and a proof in the general case has been also obtained by W. Schmidt. The case in which $g=2$ has been investigated carefully by

Stark [1], who showed that in certain cases (e.g. q = 13) one can get bounds for $\nu_{r}(C)$ slightly better than those obtainable by (4).

Stepanov's idea is quite simple. One looks for a rational function $f$ on $C$, not identically 0 , such that
(i) f vanishes at every k-rational point of $C$, of order $\mathbf{z} \mathrm{m}$, except possibly at a fixed set of $m_{o}$ rational points of $C$.

It is now clear that

$$
m\left(v_{1}(c)-m_{0}\right) \leq \# \text { zeros of } f=\# \text { poles of } f
$$

therefore

$$
v_{1}(c) \leq m_{0}+\frac{1}{m}(\# \text { poles of } f) .
$$

If we are able to construct $f$ with not too many poles, then we may get an useful bound for $v_{1}(C)$, essentially of the same strength as (4).

The construction of $f$ given by Stepanov, and also by Schmidt in the general case, is complicated, and in order to prove that $f$ vanishes of order $\geq m$ they consider derivatives or hyperderivatives of $f$, of order up to $m-1$. In the final choice, $m$ is about $q^{\frac{1}{2}}$. The argument I will give here, though based on the same idea, does not use derivations and is extremely simple.
II. As Serre pointed out to me, it is more convenient to give $C$ over the algebraic closure $\bar{k}$ of $k$, to give a Frobenius morphism $\varphi: C \rightarrow C$
of order q , and ask for

$$
v_{r}=\# \text { fixed points of } \varphi^{r} .
$$

We begin with

THEOREM 1.- Assume $q=p^{\alpha}$, where $\alpha$ is even. Then if $q>(g+1)^{4}$ we have

$$
\begin{equation*}
v_{1}<q+(2 g+1) q^{\frac{1}{2}}+1 \tag{5}
\end{equation*}
$$

For the proof, we may assume that $\varphi$ has a fixed point $x_{0}$, otherwise there is nothing to prove. Now define
$R_{m}=$ vector space of rational functions on $C / k$, such that $(f) \geq-m x{ }_{0}$.
The following facts are either obvious or trivial consequences of the RiemannRoch theorem on $C$.
(i) $\quad \operatorname{dim} R_{m} \leq m+1$
(ii) $\quad \operatorname{dim} R_{m} \geq m+1-g$,
with equality if $m>2 g-2$
(iii) $\quad \operatorname{dim} R_{m+1} \leq \operatorname{dim} R_{m}+1$.

Next, we note that since $\varphi\left(x_{0}\right)=x_{0}$, we have
(iv) $\quad R_{m} \circ \varphi \subset R_{m q}$,
(v) every element $f \circ \varphi$ of $R_{m} \circ \varphi$ is a $q-t h$ power, and we have

$$
(f \circ \varphi)=q \varphi((f))
$$

If $A$, $B$ are vector subspaces of $R_{m}, R_{n}$ we denote by $A B$ the vector subspace of $R_{m+n}$ generated by elements $f h, f \in A, h \in B$; also we denote by $R_{l}^{\left(p^{\mu}\right)}$ the subspace of $R_{\ell p^{\mu}}$ consisting of functions $f^{p^{\mu}}, f \in R_{\ell} \cdot$ Note that
(vi)

$$
\begin{aligned}
\operatorname{dim} \mathrm{R}_{\ell}\left(\mathrm{p}^{\mu}\right) & =\operatorname{dim} \mathrm{R}_{\ell} \\
\operatorname{dim} R_{m} \circ \varphi & =\operatorname{dim} R_{m}
\end{aligned}
$$

The following simple result is the key lemma in the proof.
Lemma.- If $\ell p^{\mu}<q$, the natural homomorphism

$$
R_{\ell}^{\left(p^{\mu}\right)} \otimes \otimes_{\bar{k}}\left(R_{m} \circ \varphi\right) \rightarrow R_{\ell}^{\left(p^{\mu}\right)}\left(R_{m} \circ \varphi\right)
$$

is an isomorphism.

COROLLARY.- If $\ell^{\mu}<q$ then

$$
\begin{equation*}
\operatorname{dim} R_{\ell}^{\left(p^{\mu}\right)}\left(R_{m} \circ \varphi\right)=\left(\operatorname{dim} R_{\ell}\right)\left(\operatorname{dim} R_{m}\right) \tag{6}
\end{equation*}
$$

Proof of Corollary. Obvious from (vi).

Proof of Lemma. Let ord $f$ denote the order of a function $f$ at $x_{o}$, so that

$$
\text { ord } f \geq-m \quad \text { for } f \in R_{m}
$$

By (iii), there is a basis $s_{1}, s_{2}, \ldots, s_{r}$ of $R_{m}$ such that

$$
\text { ord } s_{i}<\text { ord } s_{i+1} \quad \text { for } i=1,2, \ldots, r-1 .
$$

Now in order to prove the Lemma we have to show that if $\sigma_{i} \in R_{\ell}$ and if

$$
\sum_{i=1}^{r} \sigma_{i}^{p^{\mu}}\left(s_{i} \circ \varphi\right) \equiv 0
$$

then the $\sigma_{i}$ are also identically 0 . But assume

$$
\sum_{i=p}^{r} \sigma_{i}^{\mu} \cdot\left(s_{i} \circ \varphi\right) \equiv 0, \quad \sigma_{\rho} \not \equiv 0
$$

We find

$$
\begin{aligned}
\operatorname{ord}\left(\sigma_{\rho}^{p^{\mu}}\left(s_{\rho} \circ \varphi\right)\right) & =\operatorname{ord}\left(-\sum_{\rho+1}^{r} \sigma_{i}^{p^{\mu}}\left(s_{i} \circ \varphi\right)\right) \\
& \geq \min _{i>\rho} \operatorname{ord}\left(\sigma_{i}^{p^{\mu}}\left(s_{i} \circ \varphi\right)\right) \\
& \geq-\ell p^{\mu}+q \text { ord } s_{\rho+1}
\end{aligned}
$$

because $\operatorname{ord}\left(\sigma_{i}^{p^{\mu}}\right)=p^{\mu} \operatorname{ord}\left(\sigma_{i}\right) \geq-\ell p^{\mu} \quad$ and $\quad \operatorname{ord}\left(s_{i} \circ \varphi\right)=q \operatorname{ord}\left(s_{i}\right)$, while ord $\left(s_{i}\right)$ is strictly increasing with $i$, by our choice of the basis of $R_{m}$. Hence

$$
\begin{aligned}
p^{\mu} \text { ord } \sigma_{\rho} & \geq-\ell p^{\mu}+q\left(\text { ord } s_{\rho+1}-\text { ord } s_{\rho}\right) \\
& z-\ell p^{\mu}+q>0
\end{aligned}
$$

and $\sigma_{p}$ vanishes at $x_{0}$. But $\sigma_{\rho} \in R_{\ell}$, hence $\sigma_{\rho}$ has no poles outside $x_{0}$. Hence $\sigma_{\rho}$ has no poles and at least one zero, hence $\sigma_{\rho} \equiv 0$, a contradiction.

## Q.E.D.

Proof of Theorem 1. Assume $\ell p^{\mu}<q$. By the lemma, the map

$$
\Sigma \sigma_{i}^{p^{\mu}}\left(s_{i} \circ \varphi\right) \mapsto \Sigma \sigma_{i}^{p^{\mu}} s_{i}
$$

is well-defined and gives a homomorphism

$$
\delta: R_{\ell}^{\left(\mathrm{p}^{\mu}\right)}\left(\mathrm{R}_{\mathrm{m}} \circ \varphi\right) \rightarrow \mathrm{R}_{\ell}^{\left(\mathrm{p}^{\mu}\right)_{R_{m}} \subseteq \mathrm{R}_{\ell \mathrm{p}^{\mu}+\mathrm{m}} . . . . . .}
$$

By the Corollary of the lemma and by the Riemann-Roch theorem we have

$$
\begin{aligned}
& \operatorname{dim} \operatorname{ker}(\delta) \geq\left(\operatorname{dim} R_{\ell}\right)\left(\operatorname{dim} R_{m}\right)-\operatorname{dim} R \\
& \ell \mathrm{p}^{\mu}+\mathrm{m} \\
& \geq(\ell+1-g)(\mathrm{m}+1-\mathrm{g})-\left(\ell \mathrm{p}^{\mu}+\mathrm{m}+1-\mathrm{g}\right)
\end{aligned}
$$

if $\ell, \mathrm{m} \geq \mathrm{g}$.
Every element $f \in \operatorname{ker}(\delta)$ vanishes of order $\geq p^{\mu}$ at every fixed point of $\varphi$, except possibly at $x_{0}$. In fact, if

$$
\mathbf{f}=\Sigma \sigma_{i}^{p^{\mu}}\left(s_{i} \circ \varphi\right) \not \equiv 0
$$

we have

$$
\begin{aligned}
f(x) & =\Sigma \sigma_{i}^{p^{\mu}}(x) s_{i}(\varphi(x)) \\
& =\Sigma \sigma_{i}^{p^{\mu}}(x) s_{i}(x) \\
& =(\delta f)(x)=0
\end{aligned}
$$

hence $f$ vanishes at every fixed point of $\varphi$, except at $x_{o}$, But since every element in $R_{l}^{\left(p^{\mu}\right)}\left(R_{m} \circ \varphi\right)$ is a $p^{\mu-t h}$ power, $f$ is a $p^{\mu}$-th power.

We conclude that $f$ has at least

$$
\mathrm{p}^{\mu}\left(\nu_{1}-1\right) \text { zeros. }
$$

But $f \in R_{\ell}^{\left(p^{\mu}\right)}\left(R_{m} \circ \varphi\right) \subseteq R_{\ell p^{\mu}+m q}$, hence $f$ has at most

$$
\ell \mathrm{p}^{\mu}+\mathrm{mq} \text { poles. }
$$

We conclude that if

$$
\ell \mathrm{p}^{\mu}<\mathrm{q} \quad, \quad \ell, \mathrm{~m} \geq \mathrm{g} \quad, \quad \operatorname{dim} \operatorname{ker}(\delta)>0,
$$

i.e. if

$$
(\ell+1-g)(m+1-g)>\ell p^{\mu}+m+1-g
$$

then

$$
\begin{equation*}
v_{1} \leq \ell+m q / p^{\mu}+1 \tag{7}
\end{equation*}
$$

If $q=p^{\alpha}, \alpha$ even,$q>(g+1)^{4}$ we may choose

$$
\mu=\alpha / 2 \quad, \quad \mathrm{~m}=\mathrm{p}^{\mu}+2 \mathrm{~g} \quad, \quad \ell=\left[\frac{\mathrm{g}}{\mathrm{~g}+1} \mathrm{p}^{\mu}\right]+\mathrm{g}+1
$$

and we get the conclusion of Theorem 1 .
Q.E.D.
III. The argument given before does not give a lower bound for $\nu_{1}$, while this is needed if we want to deduce the Riemann hypothesis (3). For example, if $\quad \nu_{r}=q^{r}-\omega_{1}^{r}-\omega_{2}^{r}+1$ and $\omega_{1}=q, \omega_{2}=1$ then (2) is verified, $v_{r}$ is always 0 but (3) is false.

For the Riemann hypothesis, we note that we may assume that $q$ is an even power of p , by making a base field extension for $C$. Also, by a well-known approximation argument, it is sufficient to prove

$$
v_{1}=q+O\left(q^{\frac{1}{2}}\right)
$$

To prove this, we argue as follows.

The function field $\bar{k}(C)$ of the curve $C / \bar{k}$ contains a purely transcendental subfield $\bar{k}(t)$ such that $\bar{k}(C)$ is a separable extension of $\bar{k}(t)$. Hence there is a normal extension of $\bar{k}(t)$ which is also normal over $\bar{k}(C)$; geometrically, we have a situation

$$
C^{\prime} \rightarrow C \rightarrow \mathbb{P}^{1}
$$

where $C^{\prime} \rightarrow \mathbb{P}^{1}$ is Galois, with Galois group $G$, and $C^{\prime} \rightarrow C$ is also a Galois covering, corresponding to a subgroup $H$ of $G$. We may assume that $G$ acts on $C^{\prime}$ over $k$, by making a finite base field extension. If $x$ is a point of $\mathbb{P}^{1}$ rational over $k$ and unramified in $C^{\prime} \rightarrow \mathbb{P}^{1}$, and if $y$ is a point of C' lying over $x$, we have

$$
\varphi(\mathrm{y})=\eta \cdot \mathrm{y}
$$

for some $\eta \in G$, called the Frobenius substitution of $G$ at the point $y$. Let $\nu_{1}\left(C^{\prime}, \eta\right)$ be the number of such points of $C^{\prime}$ with Frobenius substitution $\eta$. Arguing as before, but using

$$
\delta_{\eta}: \mathrm{R}_{\ell}^{\left(\mathrm{p}^{\mu}\right)}\left(\mathrm{R}_{\mathrm{m}} \circ \varphi\right) \rightarrow \mathrm{R}_{\ell}^{\left(\mathrm{p}^{\mu}\right)}\left(\mathrm{R}_{\mathrm{m}} \circ \eta\right)
$$

instead of $\delta$, we obtain easily

$$
\begin{equation*}
v_{1}\left(c^{\prime}, \eta\right) \leq q+\left(2 g^{\prime}+1\right) q^{\frac{1}{2}}+1, \tag{8}
\end{equation*}
$$

where $\mathrm{g}^{\prime}=$ genus of $\mathrm{C}^{\prime}$. On the other hand

$$
\begin{equation*}
\sum_{\eta \in G} v_{1}\left(c^{\prime}, \eta\right)=|G| v_{1}\left(\mathbb{P}^{1}\right)+0(1) \tag{9}
\end{equation*}
$$

(the $O(1)$ takes care of the branch points of $C^{\prime} \rightarrow \mathbb{P}^{1}$ ). Since

$$
v_{1}\left(\mathbb{P}^{1}\right)=q+1
$$

comparison of (8) and (9) gives

$$
\begin{equation*}
v_{1}\left(c^{\prime}, \eta\right)=q+O\left(q^{\frac{1}{2}}\right) \tag{10}
\end{equation*}
$$

for every $\eta \in G$. We have also

$$
\sum_{\eta \in H} v_{1}\left(c^{\prime}, \eta\right)=|H| v_{1}(c)+0(1)
$$

whence by (10) we get

$$
v_{1}(c)=q+o\left(q^{\frac{1}{2}}\right),
$$
