Abstract

We consider the scalar semilinear heat equation $u_t - \Delta u = f(u)$, where $f: [0, \infty) \rightarrow [0, \infty)$ is continuous and non-decreasing but need not be convex. We completely characterise those functions f for which the equation has a local solution bounded in $L^q(\Omega)$ for all non-negative initial data $u_0 \in L^q(\Omega)$, when $\Omega \subset \mathbb{R}^d$ is a bounded domain with Dirichlet boundary conditions. For $q \in (1, \infty)$ this holds if and only if $\limsup_{s \rightarrow \infty} s^{-(1+2q/d)} f(s) < \infty$; and for $q = 1$ if and only if $\int_1^\infty s^{-(1+2/d)} F(s) ds < \infty$, where $F(s) = \sup_{1 \leq t \leq s} f(t)/t$. This shows for the first time that the model nonlinearity $f(u) = u^{1+2q/d}$ is truly the ‘boundary case’ when $q \in (1, \infty)$, but that this is not true for $q = 1$.

The same characterisations hold for the equation posed on the whole space \mathbb{R}^d provided that $\limsup_{s \rightarrow 0} f(s)/s < \infty$.

1. Introduction

This paper concerns local existence of solutions of the scalar semilinear heat equation

$$u_t - \Delta u = f(u), \quad u(0) = u_0 \geq 0, \quad (1)$$

on the whole space \mathbb{R}^d and on smooth bounded domains $\Omega \subset \mathbb{R}^d$ with Dirichlet boundary conditions, when $u_0 \in L^q(\Omega)$, $1 \leq q < \infty$. Throughout and without loss of generality we assume that Ω contains the origin.

We give a complete solution to the classical problem of characterising those functions f for which (1) has a local solution that is bounded in $L^q(\Omega)$ for all non-negative initial data in $L^q(\Omega)$. It is perhaps surprising that such results are not already available in the literature, but they are not; nor do our characterisations follow from what has previously

been proved about (1). Indeed, most previous results focus on the particular nonlinearity $f(u) = u^p$, with more general treatments assuming that f is convex. We impose no such restrictions in this paper, requiring only that $f : [0, \infty) \rightarrow [0, \infty)$ is continuous and non-decreasing.

The main contribution this paper makes is in identifying the correct characterisation for both the case $q > 1$ and $q = 1$. Given the ‘correct’ assumptions on f , the methods of proof for existence/non-existence are not difficult, but still require some care. The non-existence results rely on lower bounds on the heat kernel, and in particular on lower bounds for the action of the heat semigroup on initial conditions equal to the characteristic function of a ball. In a very imprecise way, they show that for $q > 1$ the model equation with $f(u) = u^p$ ‘tells the whole story’, but that this is decidedly not the case when $q = 1$.

Local well-posedness of (1) for smooth data falls within the scope of the standard theory of parabolic equations that goes back half a century [13]. In the early 1980s the well-posedness theory was extended by Weissler [23–25] to include initial data in Lebesgue spaces, with a locally Lipschitz source term f satisfying a Lipschitz bound of the form

$$|f(u) - f(v)| \leq C|u - v|(1 + |u|^{p-1} + |v|^{p-1}), \quad (2)$$

providing sufficient conditions for local existence (and uniqueness).

In particular, in these papers and in much subsequent work, attention was almost exclusively focused on the canonical model with $f(u) = |u|^{p-1}u$ introduced by Fujita [8]. For this particular nonlinearity, given $q \in (1, \infty)$, the pioneering results of Weissler [23–25] along with those of Giga [10] and Brezis and Cazenave [3] identify a critical exponent $p^* = 1 + 2q/d$ such that (1) with $f(u) = |u|^{p-1}u$ is locally well posed in L^q if and only if $p \leq p^*$; for $p > p^*$ one can find initial data in L^q for which there is no local solution. While for $q > 1$ the equation is well behaved when $p = p^*$, for the case $q = 1$ Celik and Zhou [6] showed that for the critical exponent $p^* = 1 + 2/d$ there are L^1 initial data for which there is no solution (resolving a problem posed in [3]).

This theory has been extended in a number of ways. One natural direction was to extend the theory towards weaker classes of data (e.g. measure-valued initial conditions), see Brezis and Friedman [5], for example. Along these lines, Baras and Pierre [2] obtained a necessary and sufficient condition on the initial condition for local existence of solutions when f is convex.

A second direction focuses on finite-time blowup versus global existence. In most of these analyses, the particular form of the Fujita nonlinearity $f(u) = |u|^{p-1}u$ or a related convexity assumption plays a crucial role, see for example [1,4,7–9,12,17]. For example, the homogeneity of u^p facilitates the use of similarity solutions – such scale invariance also makes transparent the role of the critical exponent, while for a general convex f one can use Jensen’s inequality. Note that we do not consider finite-time blowup here, but rather local non-existence, i.e. ‘immediate blowup’ in some sense.

However, most of the above results break down if we only make the assumption that f is monotonic. In this case, in order to describe fully the conditions on f ensuring that an initial condition in L^q gives rise to a local solution we need a better understanding of the delicate balance between the smoothing action of the heat flow and the converse effect of the growing source. In this paper we provide, for every $q \in [1, \infty)$, a precise characterisation of those f for which equation (1) has local solutions bounded in $L^q(\Omega)$ for all non-negative initial data $u_0 \in L^q(\Omega)$. Note that this includes the delicate case $q = 1$.

First we show that for $q \in [1, \infty)$, if

$$\limsup_{s \rightarrow \infty} s^{-(1+2q/d)} f(s) = \infty \quad (3)$$

then there exists a non-negative $u_0 \in L^q(\Omega)$ for which equation (1) has no local solution that is bounded in $L^q(\Omega)$. Since the existence of a finite limit in (3) implies that $f(s) \leq C(1 + s^{1+2q/d})$ for some constant C , monotonicity of solutions along with classical results for (4) yields local existence in this case for $q \in (1, \infty)$. It follows (see Theorem 3.4) that equation (1) has at least one local L^q -bounded solution for every non-negative $u_0 \in L^q(\Omega)$ if and only if

$$\limsup_{s \rightarrow \infty} s^{-(1+2q/d)} < \infty.$$

The ‘moral’ of this is that for $q \in (1, \infty)$, the model problem with $f(s) = s^p$ in some sense tells the whole story, since the critical case lies precisely on the boundary between local existence/non-existence. (This idea has perhaps always been implicit in the discussions in the literature, but has not had a rigorous proof until now.)

The case $q = 1$ is more delicate, and is well known to be significantly more challenging. As remarked above, Celik and Zhou [6] showed that for the canonical equation

$$u_t - \Delta u = u^p \tag{4}$$

with $p = p^* = 1 + 2/d$ there is non-negative initial data in $L^1(\mathbb{R}^d)$ and $L^1(\Omega)$ for which there is no local solution. One might therefore conjecture that for $q = 1$ the condition in (3) can be weakened to

$$\limsup_{s \rightarrow \infty} s^{-(1+2/d)} f(s) > 0$$

(i.e. the limit is finite but strictly positive) and still ensure non-existence for some non-negative $u_0 \in L^1(\Omega)$. In fact significantly more is true: we show that the condition

$$\sum_{k=1}^{\infty} s_k^{-(1+2/d)} f(s_k) = \infty$$

for some sequence such that $s_{k+1} \geq \theta s_k$ (for some $\theta > 1$) is sufficient for such a non-existence result. In particular, if f satisfies this condition there are non-negative data in $L^1(\Omega)$ for which there is no solution with $u(t) \in L^1(\Omega)$ for any $t > 0$.

For any particular f this divergent series condition seems awkward to check in practice, so we show that it is equivalent to the integral condition

$$\int_1^{\infty} s^{-(1+2/d)} F(s) ds = \infty, \quad \text{where } F(s) = \sup_{1 \leq t \leq s} \frac{f(t)}{t}. \tag{5}$$

Remarkably, if the integral in (5) is finite, then a version of an argument due to Sierżega [20] guarantees local existence of an L^1 -bounded solution for every non-negative $u_0 \in L^1(\Omega)$ (in fact the solution is in $L^\infty(\Omega)$ for every $t > 0$). As a consequence we obtain our second main result (Corollary 4.5), namely that equation (1) has at least one local L^1 -bounded solution for every non-negative $u_0 \in L^1(\Omega)$ if and only if

$$\int_1^{\infty} s^{-(1+2/d)} F(s) ds < \infty, \quad \text{where } F(s) = \sup_{1 \leq t \leq s} \frac{f(t)}{t}.$$

Here the ‘moral’ is that the model problem *does not* tell the whole story.

We note here that we do not treat the question of uniqueness in this paper, but concentrate solely on local existence. For this reason we do not require any Lipschitz-type assumptions on f (such as (2)).

The paper is organised as follows. In Section 2 we prove some preliminary lower bounds on solutions of the heat equation for an initial condition that is the characteristic function of a ball; these are the key estimates that we use in our proofs. Section 3 contains the results for $q > 1$, with Section 4 treating $q = 1$. In Section 5 we discuss the problem posed on the whole space and on a bounded domain with Neumann boundary conditions, and we end with a brief recapitulation and discussion of open problems.

2. Lower bounds on solutions of the Dirichlet heat equation

An important ingredient of our arguments is the following simple lemma, which gives a lower bound on the action of the heat equation on the characteristic function of a Euclidean ball. We write $B_r(x)$ for the open ball in \mathbb{R}^d of radius r centred at x , denote by χ_r the characteristic function of $B_r := B_r(0)$, and use ω_d for the volume of the unit ball in \mathbb{R}^d .

The solution of the heat equation on Ω with Dirichlet boundary conditions,

$$u_t - \Delta u = 0, \quad u|_{\partial\Omega} = 0, \quad u(x, 0) = u_0(x) \in L^1(\Omega)$$

can be given in terms of the Dirichlet heat kernel K_Ω by the expression

$$u(x, t) = [S(t)u_0](x) := \int_\Omega K_\Omega(x, y; t)u_0(y) \, dy.$$

The proofs of the results in this section use the following lower bound on K_Ω : if the line segment joining x and y is a distance at least δ from $\partial\Omega$, then the Dirichlet heat kernel $K_\Omega(x, y; t)$ is bounded below by the Gaussian heat kernel on \mathbb{R}^d ,

$$K_\Omega(x, y; t) \geq e^{-d^2\pi^2t/4\delta^2} (4\pi t)^{-d/2} e^{-|x-y|^2/4t} \quad \text{for all } t > 0. \tag{6}$$

(See van den Berg [22], Theorem 2 and Lemmas 8 and 9.)

Lemma 2.1. *There exists an absolute constant $c_d \in (0, 1)$, which depends only on d , such that for any $r, \delta > 0$ for which $B_{r+2\delta} \subset \Omega$,*

$$S(t)\chi_r \geq c_d \left(\frac{r}{r + \sqrt{t}}\right)^d \chi_{r+\sqrt{t}}, \tag{7}$$

for all $0 < t \leq \delta^2$.

Proof. Note that since, by assumption, $B_{r+2\delta} \subset \Omega$, it follows that for every $x \in B_{r+\sqrt{t}}$ we have $\text{dist}(x, \partial\Omega) \geq \delta$ while $0 < t \leq \delta^2$; and so for such x and t the lower bound in (6) implies that

$$\begin{aligned} [S(t)\chi_r](x) &= \int_{B_r(0)} K_\Omega(x, y; t) \, dy \\ &\geq e^{-d^2\pi^2/4} (4\pi t)^{-d/2} \int_{B_r} e^{-|x-y|^2/4t} \, dy. \end{aligned}$$

The latter integral is radially symmetric and decreasing with $|x|$ and so for $|x| \leq r + \sqrt{t}$, choosing any unit vector \mathbf{u} we can write

$$\begin{aligned} [S(t)\chi_r](x) &\geq e^{-d^2\pi^2/4} (4\pi t)^{-d/2} \int_{B_r((r+\sqrt{t})\mathbf{u})} e^{-|z|^2/4t} \, dz \\ &= e^{-d^2\pi^2/4} \pi^{-d/2} \int_{B_{r/2\sqrt{t}}((\frac{1}{2} + \frac{r}{2\sqrt{t}})\mathbf{u})} e^{-|w|^2} \, dw. \end{aligned}$$

Observing that

$$B_{r/2\sqrt{t}}((\frac{1}{2} + \frac{r}{2\sqrt{t}})\mathbf{u}) \subseteq B_{\rho/2\sqrt{t}}((\frac{1}{2} + \frac{\rho}{2\sqrt{t}})\mathbf{u})$$

if $\rho \geq r$, it follows that for $r/\sqrt{t} \geq 1$ we have

$$[S(t)\chi_r](x) \geq e^{-d^2\pi^2/4} \pi^{-d/2} \omega_d \int_{B_{1/2}(\mathbf{u})} e^{-|w|^2} \, dw =: c'_d.$$

On the other hand, if $r/\sqrt{t} \leq 1$ then

$$[S(t)\chi_r](x) \geq e^{-d^2\pi^2/4} \pi^{-d/2} \left(\frac{r}{2\sqrt{t}}\right)^d e^{-9/4} =: c''_d(r/\sqrt{t})^d.$$

So with $c_d = \min(c'_d, c''_d)$

$$[S(t)\chi_r](x) \geq c_d \left(\frac{r}{\max(r, \sqrt{t})} \right)^d \geq c_d \left(\frac{r}{r + \sqrt{t}} \right)^d. \quad \square$$

We will use this result in the form of one of the following two simple corollaries.

Corollary 2.2. *There exists an absolute constant $\alpha_d > 0$, depending only on d , such that for any $r, \delta > 0$ for which $B_{r+2\delta} \subset \Omega$,*

$$\int_{\Omega} S(t)\chi_r \, dx \geq \alpha_d r^d,$$

for all $0 < t \leq \delta^2$.

Proof. Integrating the inequality in (7) over Ω yields

$$\int_{\Omega} S(t)\chi_r \, dx \geq c_d \left(\frac{r}{r + \sqrt{t}} \right)^d \int_{\Omega} \chi_{r+\sqrt{t}} \, dx = c_d \omega_d r^d. \quad \square$$

Corollary 2.3. *There exists an absolute constant $\beta_d > 0$, depending only on d , such that for any $r, \delta > 0$ for which $B_{r+2\delta} \subset \Omega$,*

$$S(t)\chi_r \geq \beta_d \chi_{r+\sqrt{t}},$$

for all $0 < t \leq \min(\delta^2, r^2)$.

3. Initial data in $L^q(\Omega)$, $q \in (1, \infty)$

Given these preliminaries we can prove our first non-existence result. We take the following definition from [18] as our (essentially minimal) definition of a solution of (1). Note that any classical or mild solution is a local integral solution in the sense of this definition [18, pp. 77–78].

Definition 3.1. Given $f : [0, \infty) \rightarrow [0, \infty)$ and $u_0 \geq 0$ we say that u is a *local integral solution* of (1) on $[0, T)$ if $u : \Omega \times [0, T) \rightarrow [0, \infty]$ is measurable, finite almost everywhere, and satisfies

$$u(t) = S(t)u_0 + \int_0^t S(t-s)f(u(s)) \, ds \tag{8}$$

almost everywhere in $\Omega \times [0, T)$.

We will be interested in solutions with non-negative initial data $u_0 \in L^q(\Omega)$ that remain bounded in $L^q(\Omega)$. To this end we make the following definition.

Definition 3.2. We say that u is a *local L^q solution* of (1) if u is a local integral solution on $[0, T)$ for some $T > 0$ and $u \in L^\infty((0, T); L^q(\Omega))$. If every non-negative $u_0 \in L^q(\Omega)$ gives rise to a local L^q solution then we say that (1) has the *local existence property in $L^q(\Omega)$* .

We now show that there are non-negative initial conditions in $L^q(\Omega)$ for which there is no local L^q solution if f satisfies the asymptotic growth condition

$$\limsup_{s \rightarrow \infty} s^{-(1+2q/d)} f(s) = \infty$$

(which is (9), below). This condition is modelled on the stronger condition

$$\limsup_{s \rightarrow \infty} s^{-\gamma} f(s) = \infty \quad \text{for some } \gamma > q(1 + 2/d),$$

which was used by Laister et al. in [15] to construct a non-negative initial condition in $L^q(\Omega)$ for which any local integral solution is not in $L^1_{\text{loc}}(\Omega)$ for any $t > 0$ small (a stronger form of non-existence than we obtain in Theorem 3.3). (A similar condition was used to analyse the problem on the whole space in [14].)

Note that our assumption in Theorem 3.3 does not imply any lower bounds on the function f itself, nor does our result require them; for example, we impose no condition on the behaviour of

$$\liminf_{s \rightarrow \infty} s^{-(1+2q/d)} f(s),$$

as in Weissler [24] (Theorem 5, Corollaries 5.1 and 5.2), nor do we require f to be continuous.

Theorem 3.3. *Let $f : [0, \infty) \rightarrow [0, \infty)$ be non-decreasing. If $q \in [1, \infty)$ and*

$$\limsup_{s \rightarrow \infty} s^{-(1+2q/d)} f(s) = \infty \tag{9}$$

then there exists a non-negative $u_0 \in L^q(\Omega)$ such that

$$u_t - \Delta u = f(u), \quad u|_{\partial\Omega} = 0, \quad u(0) = u_0 \tag{10}$$

has no local L^q solution.

Proof. Set $p = 1 + (2q/d)$. It follows from (9) that we can choose a sequence ϕ_k such that

$$\phi_k \geq k \quad \text{and} \quad f(\phi_k) \geq \phi_k^p e^{k/q}.$$

We now construct an initial condition in $L^q(\Omega)$ that is the sum of characteristic functions on a sequence of balls of decreasing radius. More precisely, set

$$r_k = \varepsilon \phi_k^{-q/d} k^{-2q/d},$$

and choose the initial data

$$u_0(x) = \sum_{k=1}^{\infty} u_k, \quad u_k = \beta_d^{-1} \phi_k \chi_{r_k},$$

where β_d is the constant from Corollary 2.3 and ε is chosen sufficiently small that $B_{3r_k} \subset \Omega$ for every k . Noting that

$$\|u_k\|_{L^q}^q = \omega_d r_k^d \beta_d^{-q} \phi_k^q = \omega_d \left(\varepsilon \phi_k^{-q/d} k^{-2q/d} \right)^d \beta_d^{-q} \phi_k^q = \omega_d \beta_d^{-q} \varepsilon^d k^{-2q},$$

i.e. that $\|u_k\|_{L^q} = \omega_d^{1/d} \beta_d^{-1} \varepsilon^{d/q} k^{-2}$, it follows that

$$\|u_0\|_{L^q} \leq \sum_k \|u_k\|_{L^q} = \omega_d^{1/d} \beta_d^{-1} \varepsilon^{d/q} \sum_k k^{-2} < \infty.$$

Now, if a solution $u(t)$ of (10) exists, then it can be written using the variation of constants formula,

$$u(t) = S(t)u_0 + \int_0^t S(t-s)f(u(s)) \, ds. \tag{11}$$

Since $u \geq 0$ and $f \geq 0$, it is immediate that

$$u(t) \geq S(t)u_0 \geq S(t)u_k, \tag{12}$$

for any choice of k . Choosing and fixing one k for now, we can neglect the first term in (11) and use the lower bound in (12) to obtain

$$u(t) \geq \int_0^t S(t-s)f(S(s)u_k) ds, \tag{13}$$

since f is non-decreasing. To aid readability, and in a slight abuse of notation, we now write $\chi(r)$ for χ_r .

Corollary 2.3 with $\delta = r_k$ implies that

$$S(s)u_k = S(s)[\beta_d^{-1}\phi_k\chi(r_k)] \geq \phi_k\chi(r_k + \sqrt{t}) \geq \phi_k\chi(r_k), \quad 0 \leq s \leq r_k^2,$$

and so

$$f(S(s)u_k) \geq f(\phi_k)\chi(r_k), \quad 0 \leq s \leq r_k^2,$$

since f is non-decreasing. Using Corollary 2.3 again

$$S(t-s)f(S(s)u_k) \geq \beta_d f(\phi_k)\chi(r_k), \quad 0 \leq s \leq t \leq r_k^2.$$

Now, using the lower bound in (13), it follows that for any¹ $t \in [t_k/2, t_k]$, where $t_k = r_k^2$,

$$\begin{aligned} [u(t)](x) &\geq \int_0^t S(t-s)f(S(s)u_0) ds \\ &\geq \int_0^{r_k^2/2} \beta_d f(\phi_k)\chi(r_k) ds \\ &\geq \frac{1}{2}\beta_d r_k^2 f(\phi_k)\chi(r_k). \end{aligned}$$

Thus

$$\begin{aligned} \|u(t)\|_{L^q}^q &\geq \int_{B(r_k)} |u(t)|^q dx \geq c r_k^{2q} f(\phi_k)^q r_k^d \\ &= c r_k^{d+2q} f(\phi_k)^q \\ &\geq c[\varepsilon\phi_k^{-q/d}k^{-2q/d}]^{d+2q} \phi_k^{[1+(2q/d)]q} e^k \\ &= c k^{-2q(1+2q/d)} e^k. \end{aligned}$$

Since the right-hand side tends to infinity as $k \rightarrow \infty$, it follows that u is not an element of $L^\infty((0, T); L^q(\Omega))$ for any $T > 0$. \square

We remarked above that Laister et al. [15] showed that under the stronger condition

$$\limsup_{s \rightarrow \infty} s^{-\gamma} f(s) = \infty, \quad \gamma > q(1 + 2/d)$$

there is non-negative initial data in $L^q(\Omega)$ for which any local solution is not in $L^1_{loc}(\Omega)$ for all small $t > 0$. It is an interesting open question whether such strong blowup still occurs under the weaker condition in Theorem 3.3.

A combination of the blowup result of Theorem 3.3 and classical results for the Fujita equation now give our first characterisation theorem, on local existence in $L^q(\Omega)$ when $q > 1$.

Theorem 3.4. *Let $f : [0, \infty) \rightarrow [0, \infty)$ be non-decreasing and continuous. If $q \in (1, \infty)$ then (10) has the local existence property in $L^q(\Omega)$ if and only if*

$$\limsup_{s \rightarrow \infty} s^{-(1+2q/d)} f(s) < \infty. \tag{14}$$

¹ We prove a lower bound valid for t in an interval since a priori our definition of a local L^q solution requires only that $u(t) \in L^q$ for almost every t .

Proof. It remains only to show that (10) has a local solution bounded in $L^q(\Omega)$ when (14) holds. In this case it follows that there exists a constant C such that

$$f(s) \leq C(1 + s^p), \quad \text{where } p = 1 + 2q/d,$$

and now one can use comparison (see Theorem 1 in Robinson and Sierżęga [19], for example) and standard existence results for the equation

$$u_t - \Delta u = C(1 + u^p)$$

(Corollary 3.2 in Weissler [24]) to guarantee that (10) has the local $L^q(\Omega)$ existence property. \square

One could rephrase the above result in terms of the quantity

$$\gamma^* = \sup\{\gamma \geq 0 : \limsup_{s \rightarrow \infty} s^{-\gamma} f(s) = \infty\}.$$

With $q^* = d(\gamma^* - 1)/2$ equation (10) does not enjoy local existence for all non-negative initial data in L^q for $q < q^*$, but does for $q > q^*$. In this way q^* defines a ‘critical exponent’ for the general class of non-decreasing f we consider here. Provided that $q^* > 1$, local existence/non-existence in the critical space L^{q^*} is determined by the behaviour of

$$\limsup_{s \rightarrow \infty} s^{-\gamma^*} f(s).$$

When $q^* = 1$ the situation is more delicate and somewhat surprising, as we now show.

4. Initial data in $L^1(\Omega)$

4.1. A condition for non-existence of a local L^1 solution

As just remarked, the behaviour of solutions for initial data in $L^1(\Omega)$ is more delicate. Celik and Zhou [6] showed that when $f(s) = s^{1+2/d}$, there is initial data in $L^1(\Omega)$ for which there is no local L^1 solution. This suggests that when $q = 1$ the requirement of Theorem 3.3 can be weakened. Indeed, the requirement that the sum in (15) diverges is clearly weaker than the asymptotic condition,

$$\limsup_{s \rightarrow \infty} s^{-(1+2/d)} f(s) > 0;$$

blowup can even occur for certain f for which the above lim sup is zero, such as $f(s) = s^{1+2/d}/\log(e + s)^\beta$ with $0 < \beta \leq 1$. In particular, algebraic growth $f(s) = s^{1+2/d}$ is not in fact the true ‘boundary’ for L^1 blowup. We examine this example in a little more detail in Section 4.4.

Note that in the statement of the following theorem we do not include the hypothesis that f is continuous; this is not required for this blowup result.

Theorem 4.1. *Suppose that $f : [0, \infty) \rightarrow [0, \infty)$ is non-decreasing and that there exists a sequence $\{s_k\}$ such that*

$$s_{k+1} \geq \theta s_k \quad \text{for some } \theta > 1,$$

and

$$\sum_{k=1}^{\infty} s_k^{-p} f(s_k) = \infty, \tag{15}$$

where $p = 1 + \frac{2}{d}$. Then there exists a non-negative initial condition $u_0 \in L^1(\Omega)$ such that

$$u_t - \Delta u = f(u), \quad u|_{\partial\Omega} = 0, \quad u(x, 0) = u_0, \tag{16}$$

has no local integral solution that remains in $L^1_{\text{loc}}(\Omega)$ for $t > 0$ (so in particular no local L^1 solution exists).

Before we give the proof proper, it is instructive to present a much simplified argument for the ‘ L^1 -like’ initial data $u_0 = \delta_0$, a delta function centred at the origin (such data is L^1 -like so far as $\int \delta_0 = 1$). To further simplify the argument we pose the problem on the whole space \mathbb{R}^d .

Since in this case

$$[S(s)\delta_0](x) = (4\pi s)^{-d/2} e^{-|x|^2/4s}$$

it follows that for each k ,

$$S(s)\delta_0(x) \geq \phi_k \chi_{\sqrt{s}} \quad \text{for } s \leq t_k := c\phi_k^{-2/d}$$

(where $c = e^{-1/2d}/4\pi$).

Now for any $t > 0$, using the fact that $\int_{\mathbb{R}^d} S(t)\chi_r = \omega_d r^d$ and arguing as in the proof of [Theorem 3.3](#),

$$\begin{aligned} \int_{\mathbb{R}^d} u(t; \delta_0) &\geq \int_{\mathbb{R}^d} \int_0^t S(t-s) f(S(s)\delta_0) \, ds \\ &\geq \int_{\mathbb{R}^d} \sum_k \int_{t_{k+1}}^{t_k} S(t-s) f(S(s)\delta_0) \, ds \\ &\geq \sum_k f(\phi_k) \int_{t_{k+1}}^{t_k} \int_{\mathbb{R}^d} S(t-s) \chi_{\sqrt{s}} \, ds \\ &= \omega_d \sum_k f(\phi_k) \int_{t_{k+1}}^{t_k} s^{d/2} \, ds \\ &= c\omega_d \sum_k f(\phi_k) (t_k^{(2+d)/2} - t_{k+1}^{(2+d)/2}) \\ (t_k = c\phi_k^{-2/d}) \quad &\geq c'\omega_d \sum_k f(\phi_k) (\phi_k^{-p} - \phi_{k+1}^{-p}) \\ (\phi_{k+1} \geq \theta\phi_k) \quad &\geq c'(1 - \theta^{-p})\omega_d \sum_k f(\phi_k) \phi_k^{-p} = \infty, \end{aligned}$$

using (15). The proof of [Theorem 4.1](#) will follow very similar lines.

Proof of Theorem 4.1. Define $\phi_k = c_d^{-1} s_k$, and set

$$u_n(x) = \frac{1}{n^2} \alpha_n^d \chi(1/\alpha_n), \quad \text{where } \alpha_n = (n^2 \phi_{\zeta_n})^{1/d},$$

with ζ_n to be chosen later. Let

$$u_0(x) = \sum_{n=n_0}^{\infty} u_n(x),$$

with n_0 chosen such that

$$\frac{1}{\alpha_{n_0}} < \delta_0 := \frac{1}{3} \inf_{x \in \partial\Omega} |x|.$$

Note that $1/\alpha_n \leq \delta_0$ and so $B_{1/\alpha_n + 2\delta_0} \subset \Omega$ for all $n \geq n_0$, and that

$$\|u_0\|_{L^1} \leq \sum_{n=1}^{\infty} \|u_n\|_{L^1} = \omega_d \sum_{n=1}^{\infty} n^{-2} < \infty.$$

Arguing as in the proof of [Theorem 3.3](#), for any choice of n we have

$$\int_{\Omega} u(t; u_0) \, dx \geq \int_{\Omega} \int_0^t S(t-s) f(S(s)u_n) \, ds \, dx.$$

We now consider the action of the heat semigroup on the initial data $v_0 = \psi \alpha^d \chi_{1/\alpha}$. It follows from [Lemma 2.1](#) with $r = 1/\alpha$ and $\delta = \delta_0$ that

$$S(s)v_0 \geq c_d \psi \frac{\alpha^d}{(1 + \alpha^2 s)^{d/2}} \chi_{(1/\alpha) + \sqrt{s}},$$

so $[S(s)v_0](x) \geq c_d \phi_k$ for

$$|x| \leq \frac{1}{\alpha} + \sqrt{s} \quad \text{while} \quad s \leq t_k = \min \left(\delta_0^2, \left(\frac{\psi}{\phi_k} \right)^{2/d} - \frac{1}{\alpha^2} \right),$$

and this range is non-empty provided that $\phi_k \leq \psi \alpha^d$.

Now for any $0 < t < \delta_0^2$, using [Corollary 2.2](#) we have

$$\begin{aligned} \int_{\Omega} \int_0^t S(t-s) f(S(s)v_0) \, ds \, dx &\geq \sum_k \int_{\Omega} \int_{t_{k+1}}^{t_k} S(t-s) f(S(s)v_0) \, ds \, dx \\ &= \sum_k \int_{t_{k+1}}^{t_k} \int_{\Omega} S(t-s) f(S(s)v_0) \, dx \, ds \\ &\geq c' \sum_k f(c_d \phi_k) \int_{t_{k+1}}^{t_k} \int_{\Omega} S(t-s) \chi_{\alpha^{-1} + \sqrt{s}} \, dx \, ds \\ &\geq \alpha_d c' \sum_k f(c_d \phi_k) \int_{t_{k+1}}^{t_k} \left(\frac{1}{\alpha} + \sqrt{s} \right)^d \, ds \\ &\geq c'' \sum_k f(c_d \phi_k) \int_{t_{k+1}}^{t_k} s^{d/2} \, ds, \end{aligned}$$

where the sum in k is taken over those values for which

$$\frac{1}{\alpha^d} \leq \frac{\psi}{\phi_k} \leq \left(t + \frac{1}{\alpha^2} \right)^{d/2}.$$

Let us consider k that satisfy this requirement and the additional constraint that $\phi_{k+1}/\alpha^d \psi \leq 1/2$. For each such k we have

$$\begin{aligned} \int_{t_{k+1}}^{t_k} s^{d/2} \, ds &= \frac{2}{2+d} (t_k^{d/2+1} - t_{k+1}^{d/2+1}) \\ &= \frac{2}{2+d} \left\{ \left[\left(\frac{\psi}{\phi_k} \right)^{2/d} - \frac{1}{\alpha^2} \right]^{d/2+1} - \left[\left(\frac{\psi}{\phi_{k+1}} \right)^{2/d} - \frac{1}{\alpha^2} \right]^{d/2+1} \right\} \\ &= \frac{2}{2+d} \left(\frac{\psi}{\phi_k} \right)^{1+2/d} \left[\left(1 - \left(\frac{\phi_k}{\alpha^d \psi} \right)^{2/d} \right)^{d/2+1} - \frac{\phi_k^{1+2/d}}{\phi_{k+1}^{1+2/d}} \left(1 - \left(\frac{\phi_{k+1}}{\alpha^d \psi} \right)^{2/d} \right)^{d/2+1} \right] \end{aligned}$$

$$\begin{aligned} &\geq \frac{2}{2+d} \left(\frac{\psi}{\phi_k}\right)^{1+2/d} \left(1 - \frac{\phi_k^{1+2/d}}{\phi_{k+1}^{1+2/d}}\right) \left(1 - \left(\frac{\phi_{k+1}}{\alpha^d \psi}\right)^{2/d}\right)^{d/2+1} \\ &\geq \sigma \left(\frac{\psi}{\phi_k}\right)^{1+2/d}, \end{aligned}$$

using the facts that $\phi_{k+1} \geq \theta \phi_k$ and $\phi_{k+1}/\alpha^d \psi \leq 1/2$. So certainly

$$\begin{aligned} \int_{\Omega} \int_0^t S(t-s) f(S(s)v_0) ds &\geq c'' \sigma \sum_k f(c_d \phi_k) \left(\frac{\psi}{\phi_k}\right)^{1+2/d} \\ &= c''' \psi^p \sum_k f(s_k) s_k^{-p}, \end{aligned}$$

where the sum is taken over

$$\left\{ k : \frac{2}{\alpha^d} \leq \frac{\psi}{\phi_{k+1}} < \frac{\psi}{\phi_k} \leq \left(t + \frac{1}{\alpha^2}\right)^{d/2} \right\}. \tag{17}$$

For any fixed t with $0 < t < \delta_0^2$, once n is sufficiently large that $tn^{4/d} \geq 1$ the set in (17) with $\psi = n^{-2}$ and $\alpha = \alpha_n = (n^2 \phi_{\zeta_n})^{1/d}$ certainly contains

$$\{k : 1 \leq \phi_k \quad \text{and} \quad \phi_{k+1} \leq \frac{1}{2} \phi_{\zeta_n}\} = \{k : k_0 \leq k \leq k_n\},$$

where k_0 is the smallest value of k for which $\phi_k \geq 1$ and by choosing ζ_n such that $\phi_{k_n+1} \leq \frac{1}{2} \phi_{\zeta_n}$ we can achieve any desired sequence k_n .

Since $\sum_{k=1}^{\infty} f(s_k) s_k^{-p} = \infty$ (by (15)) we can choose k_n such that

$$n^{-2p} \sum_{k=k_0}^{k_n} f(s_k) s_k^{-p}$$

diverges as $n \rightarrow \infty$. \square

We note that if we assume in addition that $f(s) \geq cs$ for some $c > 0$, then under the conditions in Theorem 4.1 there is in fact no local integral solution of (16). Indeed, suppose that there is a local integral solution $u : \Omega \times [0, T) \rightarrow [0, \infty)$. Then by Definition 3.1, u is finite almost everywhere on $\Omega \times [0, T)$. Since all our estimates are performed within B_{δ_0} , we have in fact shown that there is a ball $B \subset \Omega$ and a time $\delta_0^2 > 0$ such that

$$\int_B u(y, s) dy = \infty \quad \text{for all } s \in (0, \delta_0^2).$$

Now fix $\tau = \min(T, \delta_0^2)$ and choose any $(x, t) \in B \times [\tau/2, \tau]$. Since u satisfies (8),

$$\begin{aligned} u(x, t) &\geq \int_0^t \int_{\Omega} K(x, y; t-s) f(u(y, s)) dy ds \\ &\geq c \int_0^{\tau/4} \int_B K(x, y; t-s) u(y, s) dy ds, \end{aligned}$$

using the assumption that $f(s) \geq cs$. For $s \in [0, \tau/4]$ and $t \in [\tau/2, \tau]$ we have $t - s \in [\tau/4, \tau]$. By the continuity and positivity of K there exists $\kappa > 0$ such that

$$K(x, y; \sigma) \geq \kappa \quad \text{for all } (x, y, \sigma) \in B \times B \times [\tau/4, \tau],$$

whence

$$u(x, t) \geq c\kappa \int_0^{\tau/4} \int_B u(y, s) \, dy \, ds = \infty.$$

Therefore $u = \infty$ on $B \times [\tau/2, \tau]$, contradicting the requirement that u is finite almost everywhere on $\Omega \times [0, T)$.

4.2. An equivalent integral condition for blowup

Since the condition in (15) is potentially awkward to check in practice, we now formulate an equivalent integral condition. Note that when $f(s)/s$ is non-decreasing, the integral condition in (ii) of the lemma below becomes the more conventional

$$\int_1^\infty s^{-(1+p)} f(s) \, ds = \infty.$$

Lemma 4.2. *Suppose that $f : [0, \infty) \rightarrow [0, \infty)$ is non-decreasing and $p > 1$. Then the following two conditions are equivalent.*

(i) *There exists a sequence $\{s_k\}$ such that $s_{k+1} \geq \theta s_k$, $\theta > 1$ and*

$$\sum_{k=1}^\infty s_k^{-p} f(s_k) = \infty.$$

(ii) $\int_1^\infty s^{-p} F(s) \, ds = \infty$, where $F(s) = \sup_{1 \leq t \leq s} \frac{f(t)}{t}$.

Proof. First we show that (i) implies (ii). We can augment the sequence $\{s_k\}$ to a new sequence σ_k so that we still have

$$\sum_{k=0}^\infty \sigma_k^{-p} f(\sigma_k) = \infty$$

but now in addition, choosing $1 < \alpha < p$, we can ensure that

$$1 < \theta \leq \frac{\sigma_{k+1}}{\sigma_k} \leq \theta^\alpha,$$

by including points $\theta^j s_k$ until $s_{k+1} \leq \theta^{j+\alpha} s_k$.

Setting $\sigma_0 = 1$ we can write

$$\begin{aligned} \int_1^\infty s^{-p} F(s) \, ds &= \sum_{k=0}^\infty \int_{\sigma_k}^{\sigma_{k+1}} s^{-p} F(s) \, ds \geq \sum_{k=0}^\infty \int_{\sigma_k}^{\sigma_{k+1}} s^{-p} F(\sigma_k) \, ds \\ &\geq \frac{1}{p-1} \sum_{k=0}^\infty (\sigma_k^{-(p-1)} - \sigma_{k+1}^{-(p-1)}) \frac{f(\sigma_k)}{\sigma_{k+1}} \\ &= \frac{1}{p-1} \sum_{k=0}^\infty \sigma_k^{-p} f(\sigma_k) \left\{ \frac{\sigma_k}{\sigma_{k+1}} - \frac{\sigma_k^p}{\sigma_{k+1}^p} \right\} \\ &\geq \frac{1}{p-1} (\theta^{-\alpha} - \theta^{-p}) \sum_{k=0}^\infty \sigma_k^{-p} f(\sigma_k), \end{aligned}$$

from which (ii) follows.

We now show that (ii) implies (i). Choose $\theta > 1$ and for $k = 0, 1, 2, \dots$ let $\sigma_k = \theta^k$; note that $F(s) \leq F(\sigma_{n+1})$ for all $s \in (\sigma_n, \sigma_{n+1}]$. There exists a sequence $\{k_n\}$ with $k_n \leq n$ and $k_{n+1} \geq k_n$ such that $F(\sigma_{n+1}) = f(\tau_n)/\tau_n$ for some $\tau_n \in (\sigma_{k_n}, \sigma_{k_n+1}]$. Thus

$$F(s) \leq F(\sigma_{n+1}) \leq \frac{f(\sigma_{k_n+1})}{\sigma_{k_n}} \quad \text{for all } s \in (\sigma_n, \sigma_{n+1}].$$

Therefore

$$\int_1^\infty s^{-p} F(s) \, ds = \sum_{n=1}^\infty \int_{\sigma_n}^{\sigma_{n+1}} s^{-p} F(s) \, ds \leq \sum_{n=1}^\infty \frac{f(\sigma_{k_n+1})}{\sigma_{k_n}} \int_{\sigma_n}^{\sigma_{n+1}} s^{-p} \, ds.$$

Now observe that there is an increasing sequence n_j such that

$$k_{n_j} = k_n < k_{n_{j+1}} \quad \text{for } n = n_j, \dots, n_{j+1} - 1,$$

and so

$$\begin{aligned} \sum_{n=1}^\infty \frac{f(\sigma_{k_n+1})}{\sigma_{k_n}} \int_{\sigma_n}^{\sigma_{n+1}} s^{-p} \, ds &= \sum_j \frac{f(\sigma_{k_{n_j}+1})}{\sigma_{k_{n_j}}} \int_{\sigma_{k_{n_j}}}^{\sigma_{k_{n_j}+1}} s^{-p} \, ds \\ &< \sum_j \frac{f(\sigma_{k_{n_j}+1})}{\sigma_{k_{n_j}}} \int_{\sigma_{k_{n_j}}}^\infty s^{-p} \, ds \\ &\leq \frac{1}{p-1} \sum_{n=1}^\infty \frac{f(\sigma_{k_n+1})}{\sigma_{k_n}} \sigma_{k_n}^{1-p} \\ &= \frac{\theta^p}{p-1} \sum_{j=1}^\infty \sigma_{k_{n_j}+1}^{-p} f(\sigma_{k_{n_j}+1}). \end{aligned}$$

Taking $s_j = \sigma_{k_{n_j}+1}$ yields (i). \square

4.3. An integral condition for local existence

We now show that the integral condition in (ii) of Lemma 4.2 is sufficient for the L^1 local existence property. We will use the following theorem from Robinson and Sierżęga [19] (Theorem 1, after Weissler [25]) which guarantees the existence of a solution $u(t)$ of (1) given the existence of a supersolution $v(t)$, i.e. a function satisfying (18). For later use we remark that $\Omega = \mathbb{R}^d$, with $S(t)$ denoting the action of the heat semigroup (defined by convolution with the Gaussian kernel) is an admissible choice in Theorem 4.3 (see discussion in the ‘Final comments’ in [19]).

Theorem 4.3. *Take $u_0 \geq 0$. If $f : [0, \infty) \rightarrow [0, \infty)$ is continuous and non-decreasing and there exists a $v \in L^1((0, T) \times \Omega)$ such that*

$$S(t)u_0 + \int_0^t S(t-s)f(v(s)) \, ds \leq v(t) \quad \text{for all } t \in [0, T] \tag{18}$$

then there exists a local integral solution u of (1) on $[0, T]$ with $u(x, t) \leq v(x, t)$ for all $x \in \Omega$ and $t \in [0, T]$.

This theorem is proved by constructing a sequence of supersolutions $v_n(t)$ defined by setting $v_0(t) = v(t)$ and

$$v_{n+1}(t) = \mathcal{F}(v_n) := S(t)u_0 + \int_0^t S(t-s)f(v_n(s)) \, ds.$$

Such a sequence is monotonically decreasing, is bounded below by $S(t)u_0$, and hence has a pointwise limit $u(t)$ which can be shown to satisfy

$$S(t)u_0 + \int_0^t S(t-s)f(u(s)) \, ds = u(t) \quad \text{for all } t \in [0, T]$$

using the Monotone Convergence Theorem.

Using this result we prove a local existence theorem; the argument is adapted from the proof of Proposition 7.2 in Sierżęga [20]. Note that our standing assumption that Ω is bounded is an important ingredient in the proof, since we require $\chi_\Omega \in L^1(\Omega)$.

Theorem 4.4. *If $f : [0, \infty) \rightarrow [0, \infty)$ is continuous, non-decreasing, and*

$$\int_1^\infty s^{-(1+2/d)} F(s) \, ds < \infty, \quad \text{where} \quad F(s) = \sup_{1 \leq t \leq s} \frac{f(t)}{t} \quad (19)$$

then for every non-negative $u_0 \in L^1(\Omega)$ there exist a $T > 0$ such that (10) has a solution

$$u \in L_{\text{loc}}^\infty((0, T); L^\infty(\Omega)) \cap C^0([0, T]; L^1(\Omega)).$$

In particular, (10) has the local L^1 existence property.

Proof. If $u_0 = 0$ then $v(t) \equiv \chi_\Omega$ is a supersolution, since

$$S(t)u_0 + \int_0^t S(t-s)f(S(s)\chi_\Omega) \, ds \leq \int_0^t S(t-s)\{f(1)\chi_\Omega\} \, ds \leq tf(1)\chi_\Omega \leq \chi_\Omega$$

for all t sufficiently small.

To treat $u_0 \neq 0$, define $\tilde{f}(s) = f(s)$ for $s \in [0, 1]$ and $\tilde{f}(s) = sF(s)$ for $s > 1$. Then $f(s) \leq \tilde{f}(s)$ and $\tilde{f}(s)/s : [1, \infty) \rightarrow [0, \infty)$ is non-decreasing. In particular, any supersolution for the equation

$$u_t - \Delta u = \tilde{f}(u) \quad (20)$$

is also a supersolution for (10), and therefore to show that (10) has a solution it suffices to find a supersolution for (20).

Rewritten in terms of \tilde{f} , the integral condition in (19) becomes

$$\int_1^\infty s^{-(2+2/d)} \tilde{f}(s) \, ds < \infty,$$

and after the substitution $s = \tau^{-d/2}$ we obtain

$$\int_0^1 \tau^{d/2} \tilde{f}(\tau^{-d/2}) \, d\tau < \infty.$$

We now show that for any $A > 1$, $v(t) = AS(t)u_0 + \chi_\Omega$ is a supersolution of (20) on some suitable time interval, i.e. satisfies the condition (18) in Theorem 4.3. In order to do this, first recall the smoothing estimate

$$\|S(t)u_0\|_{L^\infty} \leq t^{-d/2} \|u_0\|_{L^1}$$

(see Lemma 7 in Brezis and Cazenave [3], for example).

We therefore obtain

$$\begin{aligned} S(t)u_0 + \int_0^t S(t-s)\tilde{f}(v(s))\,ds &= S(t)u_0 + \int_0^t S(t-s)\tilde{f}(AS(s)u_0 + 1)\,ds \\ &= S(t)u_0 + \int_0^t S(t-s)\left(\frac{\tilde{f}(AS(s)u_0 + 1)}{AS(s)u_0 + 1}\right)(AS(s)u_0 + 1)\,ds \\ &\leq S(t)u_0 + \int_0^t S(t-s)\left\|\frac{\tilde{f}(AS(s)u_0 + 1)}{AS(s)u_0 + 1}\right\|_{L^\infty}(AS(s)u_0 + 1)\,ds, \end{aligned}$$

where for notational convenience we have written 1 in place of χ_Ω . Since the L^∞ norm is a scalar constant and $S(t-s)$ is linear, it follows that

$$\mathcal{F}(v)(t) \leq S(t)u_0 + \left\{ \int_0^t \left\|\frac{\tilde{f}(AS(s)u_0 + 1)}{AS(s)u_0 + 1}\right\|_{L^\infty} ds \right\} [AS(t)u_0 + \chi_\Omega],$$

as $S(t)\chi_\Omega \leq \chi_\Omega$ for all $t > 0$. Now, using the fact that $\tilde{f}(s)/s$ is non-decreasing for $s \geq 1$,

$$\begin{aligned} \mathcal{F}(v)(t) &\leq S(t)u_0 + \left\{ \int_0^t \frac{\tilde{f}(\|AS(s)u_0 + 1\|_{L^\infty})}{\|AS(s)u_0 + 1\|_{L^\infty}} ds \right\} [AS(t)u_0 + \chi_\Omega] \\ &\leq S(t)u_0 + \left\{ \int_0^t \frac{\tilde{f}(2As^{-d/2}\|u_0\|_{L^1})}{2As^{-d/2}\|u_0\|_{L^1}} ds \right\} [AS(t)u_0 + \chi_\Omega], \end{aligned}$$

for t sufficiently small, since

$$\|AS(s)u_0 + 1\|_{L^\infty} = \|AS(s)u_0\|_{L^\infty} + 1 \leq As^{-d/2}\|u_0\|_{L^1} + 1 \leq 2As^{-d/2}\|u_0\|_{L^1}$$

for s sufficiently small.

Therefore $\mathcal{F}(v)(t)$ is bounded above by

$$\begin{aligned} S(t)u_0 + (2Ac\|u_0\|_{L^1})^{2/d} \left(\int_0^{t(2Ac\|u_0\|_{L^1})^{-2/d}} \tau^{d/2} \tilde{f}(\tau^{-d/2})\,d\tau \right) [AS(t)u_0 + \chi_\Omega] \\ \leq AS(t)u_0 + \chi_\Omega, \end{aligned}$$

provided that t is sufficiently small. Local existence of a solution $u(t)$ with $u(t) \leq v(t) = AS(t)u_0 + \chi_\Omega$ now follows from [Theorem 4.3](#). That $u(t)$ is bounded in $L^1(\Omega)$ now follows from [Theorem 4.3](#). It follows that $u \in L^\infty_{\text{loc}}((0, T); L^\infty(\Omega))$, i.e. is a classical solution. Then from the integral condition on f , $f(u) \in L^1((0, T); L^1(\Omega))$, whence from [\(8\)](#) it follows that $u \in C^0([0, T]; L^1(\Omega))$. \square

We have therefore obtained the following characterisation of those f for which there is local existence in $L^1(\Omega)$.

Corollary 4.5. *If $f : [0, \infty) \rightarrow [0, \infty)$ is continuous and non-decreasing then [\(10\)](#) has the local L^1 existence property if and only if*

$$\int_1^\infty s^{-(1+2/d)} F(s)\,ds < \infty, \quad \text{where} \quad F(s) = \sup_{1 \leq t \leq s} \frac{f(t)}{t}.$$

We note that one can apply the ‘local existence’ part of this characterisation (i.e. [Theorem 4.4](#)) to a nonlinearity g that is not non-decreasing by finding a non-decreasing function $f(s)$ such that $g(s) \leq f(s)$, applying [Theorem 4.4](#) and then deducing local existence by comparison. The following section provides an example of this along with an illustration of the application of [Corollary 4.5](#).

4.4. An example: $f(s) = s^{1+2/d} / [\log(e + s)]^\beta$

We mentioned before the proof of [Theorem 4.1](#) that the family of nonlinearities

$$f(s) = \frac{s^p}{[\log(e + s)]^\beta}, \quad p = 1 + 2/d, \quad \beta \geq 0,$$

provides an interesting set of examples, particularly in the light of the (erroneous) expectation that $f(s) = s^{1+2/d}$ lies on the ‘boundary’ between those functions for which (1) does and does not have the local L^1 existence property.

Strictly, such a function f only falls within the scope of our results when it is non-decreasing, which occurs if and only if $\beta \leq \lambda p$, where $\lambda \simeq 3.15$ is the largest positive root of the equation $e^x = e^2 x$. It follows from [Corollary 4.5](#) that

- (i) if $0 \leq \beta \leq 1$ then (1) does not have the L^1 local existence property;
- (ii) if $1 < \beta \leq \lambda p$ then (1) does have the L^1 local existence property;

and since although when $\beta > \lambda p$ the function $f(s)$ is not monotone, it is bounded above by the monotone $s^p / \log(e + s)^{\lambda p}$, which provides a supersolution and hence (see [Theorem 6.2](#) in [Sierżęga \[20\]](#), for example)

- (iii) if $\beta > \lambda p$ then (1) does have the L^1 local existence property.

Within this family the function $f(s) = s^p / \log(e + s)$ lies on the ‘boundary’. One could refine this with the addition of an arbitrary number of repeated logarithms.

5. Results for the whole space and for Neumann boundary conditions

It is worth remarking that since they rely only on Gaussian lower bounds for the Dirichlet heat kernel, the non-existence results of [Theorems 3.3 and 4.1](#) are valid with essentially the same proofs for the equations posed on the whole space \mathbb{R}^d . They are also valid for Neumann boundary conditions ($\frac{\partial u}{\partial n} = 0$ on $\partial\Omega$), since

$$K_{\Omega_N}(x, y; t) \geq K_{\Omega_D}(x, y; t), \quad x, y \in \Omega, \quad t > 0,$$

where K_N and K_D denote the Neumann and Dirichlet heat kernels, respectively (the proof follows by comparison, or one can use probabilistic methods, see [Corollary 2.5](#) in [van den Berg \[21\]](#), for example).

However, local existence results on the whole space require some additional assumptions. It is easy to see that if $f(0) \neq 0$ then any non-negative initial condition gives rise to a solution that is not in $L^q(\mathbb{R}^d)$ for any $q \in [1, \infty)$. Indeed, since then $u(t) \geq 0$ for all $t \geq 0$ we have

$$u(t) \geq \int_0^t S(t-s) f(u(s)) \, ds \geq \int_0^t S(t-s) f(0) \, ds = t f(0) \notin L^q(\mathbb{R}^d).$$

We also require a ‘bounded derivative at zero’ condition, namely

$$\limsup_{s \rightarrow 0} \frac{f(s)}{s} < \infty. \tag{21}$$

Without this condition we can find a non-negative $u_0 \in L^q(\mathbb{R}^d)$ for which the solution is not bounded in $L^q(\mathbb{R}^d)$ for all $t > 0$.

Indeed, if (21) does not hold then there exist $s_n \rightarrow 0$ such that $s_n \leq n^{-2}$ and $f(s_n) \geq n^2 s_n$. Consider initial data

$$u_0 = \sum_{n=1}^{\infty} c_d^{-1} s_n \chi_{n^{-2/d} s_n^{-q/d}}(x_n)$$

where the x_n are chosen such that $B(x_n, n^{-2/d} s_n^{-q/d})$ are disjoint. Note that $\|u_0\|_{L^q} < \infty$ and that $n^{-2/d} s_n^{-q/d} \geq 1$.

Then

$$S(s)u_0 \geq \sum_{n=1}^{\infty} s_n \chi_{n^{-2/d} s_n^{-q/d}}(x_n)$$

for all $s \leq 1$. So for $t \leq 1$ we have

$$\begin{aligned} u(x, t) &\geq \int_0^t \sum_{n=1}^{\infty} S(t-s) n^2 s_n \chi_{n^{-2/d} s_n^{-q/d}}(x_n) \, ds \\ &\geq \int_0^t \sum_{n=1}^{\infty} c_d n^2 s_n \chi_{n^{-2/d} s_n^{-q/d}}(x_n) \, ds \\ &= t c_d \sum_{n=1}^{\infty} n^2 s_n \chi_{n^{-2/d} s_n^{-q/d}}(x_n) \end{aligned}$$

and so

$$\int_{\mathbb{R}^d} |u(x, t)|^q \, dx \geq \omega_d (t c_d)^q \sum_{n=1}^{\infty} n^{2q} s_n^q n^{-2} s_n^{-q} = \omega_d t c_d \sum_{n=1}^{\infty} n^{2(q-1)} = \infty.$$

Now, for $q > 1$ if we have, with $p = 1 + 2q/d$,

$$\limsup_{s \rightarrow \infty} s^{-p} f(s) < \infty \quad \text{and} \quad \limsup_{s \rightarrow 0} \frac{f(s)}{s} < \infty$$

then

$$f(s) \leq C(s + s^p)$$

for some $C > 0$. For $f(s) = C(s + s^p)$ we can guarantee the local L^q existence property on \mathbb{R}^d as follows. First, results guaranteeing the L^q local existence property on the whole space when $f(s) = 2Cs^p$ can be found in Weissler [23,24] (the analysis there is valid on the whole space), Theorem 1 in Giga [10], or Robinson and Sierżęga [19] (see ‘Final comments’). So given a non-negative $u_0 \in L^q(\mathbb{R}^d)$, let $u(t)$ be the local L^q solution obtained in this way. Now define $v(t) = e^{2Ct} u(t)$. Then

$$\begin{aligned} v_t - \Delta v &= 2Ce^{2Ct} u + e^{2Ct}(u_t - \Delta u) \\ &= 2Ce^{2Ct} u + e^{2Ct} 2Cu^p \\ &= 2C(v + (e^{2Ct})^{1-p} v^p) \\ &\geq C(v + v^p) \end{aligned}$$

provided that $(e^{2Ct})^{1-p} \geq 1/2$. This is legitimate since v is a strong, classical solution for $t > 0$. It then follows easily that v is a supersolution in the integral sense of Theorem 4.3 on some small time interval. The existence of such a supersolution, which is bounded in $L^q(\mathbb{R}^d)$, then implies the existence of a solution bounded in $L^q(\mathbb{R}^d)$ using Theorem 4.3.

For $q = 1$ local existence follows from the arguments in Theorem 4.4, now taking

$$F(s) = \sup_{0 \leq t \leq s} \frac{f(t)}{t}$$

and observing that if $u_0 \geq 0$ and is non-zero then $S(t)u_0 > 0$ for all $t > 0$ (this follows immediately from the expression for $S(t)u_0$ in terms of the Gaussian kernel). (If $u_0 = 0$ then obviously $u(t) = 0$ is a solution since $f(0) = 0$ by the limsup condition at $s = 0$.)

We summarise formally in the following theorem.

Theorem 5.1. *Let $f : [0, \infty) \rightarrow [0, \infty)$ be continuous and non-decreasing and let $\Omega = \mathbb{R}^d$. Then*

(i) *for $q \in (1, \infty)$ equation (1) has the local L^q existence property if and only if*

$$\limsup_{s \rightarrow 0} \frac{f(s)}{s} < \infty \quad \text{and} \quad \limsup_{s \rightarrow \infty} s^{-(1+2q/d)} f(s) < \infty;$$

(ii) *equation (1) has the local L^1 existence property if and only if*

$$\limsup_{s \rightarrow 0} \frac{f(s)}{s} < \infty \quad \text{and} \quad \int_1^\infty s^{-(1+2/d)} F(s) \, ds < \infty,$$

where $F(s) = \sup_{0 \leq t \leq s} \frac{f(t)}{t}$.

6. Concluding remarks

We have completely characterised those non-negative, non-decreasing, continuous functions f for which the equation

$$u_t - \Delta u = f(u), \quad u|_{\partial\Omega} = 0, \quad u(0) = u_0 \in L^q(\Omega), \quad u_0 \geq 0,$$

has at least one local solution that is bounded in $L^q(\Omega)$. For $1 < q < \infty$ this occurs if and only if

$$\limsup_{s \rightarrow \infty} s^{-(1+2q/d)} f(s) < \infty,$$

while for $q = 1$ this occurs if and only if

$$\int_1^\infty s^{-(1+2/d)} \left(\sup_{1 \leq t \leq s} \frac{f(t)}{t} \right) \, ds < \infty. \tag{22}$$

We have also given results for the equations on the whole space \mathbb{R}^d and for the Neumann problem on a bounded domain.

The non-existence parts of our arguments are perhaps the most novel, using lower bounds on the Dirichlet heat kernel due to van den Berg [21,22] to give lower bounds on solutions of the heat equation with characteristic functions as initial data, and hence lower bounds on solutions of the semilinear problem. The L^1 case behaves very differently from the problem in spaces with higher integrability, with the appearance of the upper bound

$$sF(s) = s \sup_{1 \leq t \leq s} [f(t)/t]$$

in both the blowup and existence criteria something of a surprise.

An open question left by our L^q -based analysis is whether we have ‘strong blowup’, $u(t) \notin L^q$ for all $t > 0$, when $q > 1$ and

$$\limsup_{s \rightarrow \infty} s^{-\gamma} f(s) = \infty, \quad \gamma \in [1 + 2q/d, q(1 + 2/d)],$$

or whether there is a true transition from such strong blowup (obtained in [15] for $\gamma > q(1 + 2/d)$) to only the unbounded behaviour $\limsup_{t \rightarrow 0} \|u(t)\|_{L^q}$ (obtained here in Theorem 3.3 when $\gamma = 1 + 2q/d$). A related question is whether it is possible to exclude the existence of local integral solutions for a wider class of f than we do in the discussion at the end of Section 4.1 (we currently require $f(s) \geq Cs$ for some $C > 0$).

The relationship between our results and those of Baras and Pierre [2], who provide a necessary and sufficient condition for local existence for given initial data $u_0 \in L^1_{\text{loc}}(\Omega)$ when $f : [0, \infty) \rightarrow [0, \infty)$ is a convex function with $f(0) = 0$, is unclear. For convex f it should be possible to obtain our necessary and sufficient condition for the L^1 existence property for L^1 data (22) from their condition. However, we think that the straightforward nature of our argument and its wider applicability is a major strength, and we have not attempted this analysis.

It would be interesting to attempt to prove similar characterisation results in other scales of spaces, such as Sobolev spaces or Besov spaces. These would require different techniques, given that our current arguments do not take into account the smoothness of solutions but only their integrability.

Seeking generalisation in a different direction, one could ask whether there is a way of identifying the critical Lebesgue space for the more general class of positive but not necessarily monotone f , or even for general f with sign-changing initial data.

Finally, we note that we have not attempted here to consider the problem of uniqueness. For the nonlinearity $f(u) = |u|^{p-1}u$ Ni and Sacks [17] proved non-uniqueness for the critical value of p (Theorem 3); see also Matos and Terraneo [16] and Haraux and Weissler [11]. It would be interesting to see whether it is possible to obtain an exact characterisation of those f that admit unique solutions, perhaps based on asymptotic conditions generalising (2) in the way that our conditions for local existence generalise the growth rates of the canonical example $f(u) = |u|^{p-1}u$.

Conflict of interest statement

There are no known conflicts of interest associated with this publication.
