Presented by Olivier Pironneau

Abstract

A new symmetric local projection method built on residual bases (RELP) makes linear equal-order finite element pairs stable for the Darcy problem. The derivation is performed inside a Petrov–Galerkin enriching space approach (PGEM) which indicates parameter-free terms to be added to the Galerkin method without compromising consistency. Velocity and pressure spaces are augmented using solutions of residual dependent local Darcy problems obtained after a static condensation procedure. We prove the method achieves error optimality and indicates a way to recover a locally mass conservative velocity field. Numerical experiments validate theory.

Version française abrégée

stabilisation. Cependant, différemment de [4] et [1], la méthode proposée dans ce travail est basée sur des aspects résiduels, et donc, la méthode est naturellement consistante. Cette propriété est obtenue en cherchant la solution dans des espaces d’éléments finis contenant les solutions des problèmes de Darcy locaux, à savoir, les problèmes (11)–(13). On établit l’existence et l’unicité de solution en démontrant une condition du type type inf-sup dans le Lemme 1. Ensuite, on démontre que les erreurs d’approximation sont optimales dans les normes naturelles dans le Théorème 2, en utilisant fortement la propriété de consistance. Le Théorème 2 propose également une façon de reconstruire un champ de vitesse localement conservatif. Les tests numériques (Fig. 1 et Tableau 1) valident la théorie.

1. Introduction

Usually adopted in its mixed form, the Darcy problem is the basic tool in the study of fluid flow simulations in porous media. However, this mixed characterization is unstable when the Darcy problem is solved with equal-order linear interpolation via the Galerkin method [2]. Recently, Bochev and Dohrmann [4] stabilized such a pair for the Stokes problem with the addition to the Galerkin method of a symmetric term based on the difference between the pressure and its local projection onto polynomial spaces of one degree lower than the pressure space. Unlike most stabilized approaches, no parameter needs to be fixed. This comes at the price of relaxing consistency, although such error is shown to be at order of leading errors. A related idea in [3] recovers stability for the Darcy model by controlling the gradient of the pressure fluctuation instead. This version demands a parameter to be fixed and prevents the use of low order interpolation spaces. Moreover, the author noted a sub-optimal convergence in pressure due to controlling the gradient of the pressure fluctuation instead.

1.1. Preliminaries

Let \( \Omega \) denote an open, bounded domain in \( \mathbb{R}^2 \) with polygonal boundary \( \partial \Omega \). We seek the velocity and pressure solution \((u, p)\) to the following mixed form of the Darcy problem:

\[
\sigma \mathbf{u} + \nabla p = \mathbf{0}, \quad \nabla \cdot \mathbf{u} = g \quad \text{in} \quad \Omega, \tag{1}
\]

\[
\mathbf{u} \cdot \mathbf{n} = 0 \quad \text{on} \quad \partial \Omega, \tag{2}
\]

where \( \sigma = \frac{\mu}{\kappa} \in \mathbb{R}^+ \) in \( \Omega \), with \( \mu \) and \( \kappa \) denoting the viscosity and permeability, respectively, and \( g \) is a given source such that \( \int_{\Omega} g = 0 \).

We adopt the usual definitions for the spaces \( L^2(D), L_0^2(D), H(\text{div}, D), \) and \( H_0(\text{div}, D) \) equipped with norms \( \| \cdot \|_{0,D} \) and \( \| \cdot \|_{\text{div}, D} \), respectively, where \( D \) is a bounded set. The symmetric weak formulation of problem (1)–(2) reads: Find \((u, p) \in H_0(\text{div}, \Omega) \times L_0^2(\Omega)\) such that

\[
B((u, p), (v, q)) = (g, q)_D \quad \text{for all} \quad (v, q) \in H_0(\text{div}, \Omega) \times L_0^2(\Omega), \tag{3}
\]

where \( B((u, p), (v, q)) := (\sigma \mathbf{u}, v)_\Omega - (\nabla \cdot v, p)_\Omega - (\nabla \cdot u, q)_\Omega \), and \((\cdot, \cdot)_D\) stands for the inner-product in \( L^2(D) \).

The problem (3) is then well-posed by supposing \( g \in L_0^2(\Omega) \) (cf. [2]).

Next, we introduce a family \( \mathcal{T}_h \) of regular partitions of \( \Omega \) composed of triangles \( K \) with boundary \( \partial K \) consisting of edges \( F \). The set of internal edges of \( \mathcal{T}_h \) is \( \mathcal{E}_h \). The diameters of \( K \) and \( F \) read \( h_K \) and \( h_F \), respectively, and \( h := \max\{h_K : K \in \mathcal{T}_h\} \). Also, for each \( F = K \cap K' \in \mathcal{E}_h \) we choose a fixed unit normal vector \( \mathbf{n}_F \). The standard
outward normal vector at the edge $F$ with respect to the element $K$ is denoted by $n^K_F$, and coincides with $n_F$ in the case $F \subset \partial \Omega$. Moreover, for a scalar function $q$, one denotes its jump as the vectorial quantity $[q] := q|_K n^K_F + q|_{K'} n^{K'}_F$, and its projection by $\Pi_D(q) := \frac{1}{|D|} \int_D q$.

In what follows, $V_1$ stands for the finite element space of continuous, piecewise linear polynomials and we set $V_1 := [V_1]^2 \cap H_0(\text{div}, \Omega)$. Also, $Q_1$ is the space of piecewise linear polynomials which are continuous or discontinuous over $\Omega$ and belong to $L^2_0(\Omega)$. Denoting residuals of the momentum and mass equations, respectively, by $R^M(v_1, q_1) := -\sigma v_1 - \nabla q_1$ and $RC(g, v_1) := g - \nabla \cdot v_1$, for $(v_1, q_1)$ in $V_1 \times Q_1$, we define the following finite-dimensional space:

$$W := \{q \in H^2(T_h) \cap L^2_0(T_h) : \Delta q = \nabla \cdot R^M(v_1, q_1) \text{ in } K, \nabla q \cdot n_F = \Pi_F(R^M(v_1, q_1)) \cdot n_F \text{ on } F \subset \partial K\},$$

and its orthogonal complement in $L^2_0(T_h)$, denoted by $W^\perp$. From its definition one can prove that $W^\perp \cap Q_1 = \{0\}$. Here we use $H^1_0(T_h) := \oplus \sum_{K \in T_h} H^1_0(K)$ and $L^2_0(T_h) := \oplus \sum_{K \in T_h} L^2_0(K)$, and $H^1_0(\text{div}, T_h) := \oplus \sum_{K \in T_h} H^1_0(\text{div}, K)$.

2. The Residual Local Projection method

The symmetric RELP method reads: Find $(u_1, p_1) \in V_1 \times Q_1$ such that

$$B_s((u_1, p_1), (v_1, q_1)) = -\sum_{K \in T_h} (\Pi_K(g), q_1)_K \quad \text{for all } (v_1, q_1) \in V_1 \times Q_1,$$

where

$$B_s((u_1, p_1), (v_1, q_1)) = B((\pi(u_1), p_1), (\pi(v_1), q_1)) - \sum_{F \in \mathcal{E}_h} \frac{1}{h_F} \left(\Pi_F([p_1]), \Pi_F([q_1])\right)_F - \sum_{K \in T_h} \frac{1}{h_K} (N_K(u_1) - p_1 + \Pi_K(p_1), N_K(v_1) - q_1 + \Pi_K(q_1))_K.$$

The global functions $\pi(\cdot)$ and $N(\cdot)$ are defined such that $\pi(v_1)|_K = \pi_K(v_1)$ and $N(v_1)|_K = N_K(v_1)$, with $(\pi_K(u_1), N_K(u_1))$ given by

$$\pi_K(u_1) = \sum_{F \subset \partial K} \Pi_F(u_1 \cdot n^K_F) \varphi^K_F \quad \text{and} \quad N_K(u_1) = \sum_{F \subset \partial K} \Pi_F(u_1 \cdot n^K_F) \eta^K_F.$$

The basis $\varphi^K_F = \frac{h_F}{\sqrt{\pi h_F}}(x - x_F)$, where $x_F$ is the node opposite to the edge $F$, generates the lowest order Raviart–Thomas space and $\eta^K_F$ belongs to $L^2_0(K)$ such that $\nabla \eta^K_F = -\sigma \varphi^K_F$.

Remark 1. Continuity of the normal component of $u_1$ is shared by $\pi(u_1)$, while the tangential is not.

3. Derivation of the method

We start by looking for the solution $(u_h, q_h)$ decomposed into large and small scales, respectively, $(u_1, q_1) \in V_1 \times Q_1$ and $(u_e, q_e) \in H_0(\text{div}, \Omega) \times L^2_0(T_h)$. Then, the Petrov–Galerkin enriched method reads: Find $(u_h, p_h) \in [V_1 + H_0(\text{div}, \Omega)] \times [Q_1 + L^2_0(T_h)]$ such that

$$B((u_h, p_h), (v_h, q_h)) = -(g, q_h)_\Omega,$$

for all $(v_h, q_h) := (\pi(v_1) + \nu v_1, q_1 + q_h) \in [\pi(V_1) \oplus H_0(\text{div}, T_h)] \times \{Q_1 \oplus W^\perp\}$, where $\pi(V_1)$ represents the space generated by applying operator $\pi(\cdot)$ on functions in $V_1$. Now, using $v_h \cdot n_{\partial K} = 0$ and $p_e|_K \in L^2_0(K)$, the problem above is equivalent to the following system:

$$B((u_1, p_1), (\pi(v_1), q_1)) + \sum_{K \in T_h} \left[(\sigma u_e, \pi(v_1))_K - (\nabla \cdot u_e, q_1)_K\right] = -(g, q_1)_\Omega,$$

$$((\sigma u_e + \nabla p_e, v_b)_K + (\sigma u_1 + \nabla p_1, v_b)_K - (\nabla \cdot u_e, q_b)_K - (\nabla \cdot u_1, q_b)_K = -(g, q_b)_K.$$

Next, denoting from now on $R^M = R^M(u_1, p_1)$ and $R^C = R^C(g, u_1)$, the weak problem (8) is equivalent to
\[ \sigma u_e + \nabla p_e = R^M, \quad \nabla \cdot u_e - R^C \in W \oplus P_0(K) \quad \text{in each } K, \] (9)

where \( P_0(K) \) denotes the piecewise constant polynomial space.

We next choose boundary conditions with the intention of correcting the residual on the edges and keeping the approach conforming. To this end, we fix \( \text{results in the symmetric method (4).} \)

\[ u_e \cdot n_F = \begin{cases} R^M - \Pi_F(R^M) + \frac{1}{h_F \sigma} \Pi_F([p_1]) \cdot n_F & \text{on } F \in \mathcal{E}_h, \\ 0 & \text{elsewhere.} \end{cases} \] (10)

and \( u_e \cdot n_F = 0 \) elsewhere.

It comes from (9) that \( (u_e, p_e) \) inherits the degrees of freedom of \( (u_1, p_1) \) and that it may be split into \( (u_e, p_e) = (u^M_e, p^M_e) + (u^G_e, p^G_e) + (u^D_e, p^D_e) \), where each contribution satisfies, respectively,

\[ \sigma u^M_e + \nabla p^M_e = R^M, \quad \nabla \cdot u^M_e = 0 \quad \text{in } K, \] (11)
\[ \sigma u^G_e + \nabla p^G_e = 0, \quad \nabla \cdot u^G_e - R^C \in W \oplus P_0(K) \quad \text{in } K, \] (12)
\[ \sigma u^D_e + \nabla p^D_e = 0, \quad \nabla \cdot u^D_e \in P_0(K) \quad \text{in } K, \] (13)

and

\[ \sigma u^D_e - \nabla p^D_e \in P_0(K) \quad \text{in } K, \] (14)

\[ u^D_e \cdot n_F = \frac{1}{h_F \sigma} \Pi_F([p_1]) \cdot n_F \quad \text{on } F \subset \partial K. \] (15)

It remains to set (12) and (13). To this end, we first remark that the solution of (11) reads \( u^M_e = -u_1 + \pi(u_1) \) and \( p^M_e = p^M_e(R^M) \in W \) is given by

\[ (p_e^M)|_K = -p_1 + \Pi_K(p_1) + N_K(u_1). \] (14)

Hence, we reinforce the dependence of the enriching functions in terms of residuals and preserve the compatibility condition by closing (12) and (13) as follows:

\[ \nabla \cdot u^G_e = R^C - \Pi_K(R^C) - \frac{1}{h^2_F \sigma} p^M_e, \quad \nabla \cdot u^D_e = \frac{1}{|K| \sigma} \sum_{F \subset \partial K} \Pi_F([p_1]) \cdot n_K^F, \] (15)

where we have used a standard dimensional argument to balance \( p^M_e \).

We can now state the RELP method corresponding to solving (7) with \( (u_e, p_e) \) given by (11)–(13) and (15). Using (11), integrating by parts, and (10), the method reads: \textit{Find} \( (u_1, p_1) \in V_1 \times Q_1 \) such that

\[ B((\pi(u_1), p_1), (\pi(v_1), q_1)) + \sum_{K \in T_h} \frac{1}{h^2_K \sigma} \left( N_K(u_1) - p_1 + \Pi_K(p_1), -N_K(v_1) + q_1 \right)_K 
+ \sum_{K \in T_h} (u^D_e, \sigma \pi(v_1) + \nabla q_1)_K - \sum_{F \in \mathcal{E}_h} \frac{1}{h_F \sigma} \left( \Pi_F([p_1]), \Pi_F([q_1]) \right)_F 
= - \sum_{K \in T_h} \left[ (\Pi_K(g), q_1) + (\sigma u^G_e(g), \pi_K(v_1))_K \right], \]

where \( u^G_e(g) \) is the solution of (12)–(15) related to \( g \). The final step consists of remarking that, as \( \| \eta_F \|_{0,K} \) is of order \( h^2_K \), the term \( \sum_{K \in T_h} (\sigma u^G_e(g), \pi(v_1))_K \) is of small size compared to the leading error, and the term \( \sum_{K \in T_h} (u^D_e, \pi(v_1) + \nabla q_1)_K \) may be handled as in [1], and then neglected without compromising optimality. This results in the symmetric method (4).
4. Error analysis

We define the following mesh dependent norm:

\[ \| (u, p) \|_h = \left[ \sigma \| u \|_{0,\Omega}^2 + \sum_{K \in \mathcal{T}_h} \frac{1}{\sigma} \| \nabla p \|_{0,K}^2 + \sum_{F \in \mathcal{E}_h} \frac{1}{\sigma h_F} \| \Pi_F (p) \|_{0,F}^2 \right]^{1/2}. \] (16)

Being residual-based, the method (4) is immediately consistent. Uniqueness for the RELP method (4) holds from the following result:

**Lemma 1.** Let \( B_s(\ldots) \) be the bilinear form in (5). Then there exists a positive constant \( \beta \), independent of \( h \) and \( \sigma \), such that

\[ \sup_{(w_1, r_1) \in V_1 \times Q_1 - (0)} \frac{B_s((v_1, q_1), (w_1, r_1))}{\| (\pi(v_1), q_1) \|_h} \geq \beta \| (\pi(v_1), q_1) \|_h \]

for all \( (v_1, q_1) \in V_1 \times Q_1 \).

Standard interpolation results, Lemma 1, and consistency yield the following error estimate:

**Theorem 2.** Let \( (u, p) \in [H^1(\Omega)^2 \cap H_0(\text{div}, \Omega)] \times [H^2(\Omega) \cap L^2_0(\Omega)] \) be the solution of (3) and \( (\pi(u_1), p_1) \) be the solution of method (4). Then, there exists a positive constant \( C \), independent of \( h \) and \( \sigma \), such that

\[ \| (u - \pi(u_1), p - p_1) \|_h \leq C h \left( \sqrt{\sigma} |u|_{1,\Omega} + \frac{1}{\sqrt{\sigma}} |p|_{2,\Omega} \right), \]

\[ \| p - p_1 \|_{0,\Omega} \leq C h^2 \left( \sqrt{\sigma} |u|_{1,\Omega} + \frac{1}{\sqrt{\sigma}} |p|_{2,\Omega} \right). \]

If the space \( Q_1 \) is discontinuous and \( u \in [H^2(\Omega)^2 \cap H_0(\text{div}, \Omega)] \), we further have

\[ \| u - \pi(u_1) \|_{\text{div},\Omega} \leq C h \left( |u|_{2,\Omega} + \frac{1}{\sigma} |p|_{2,\Omega} \right), \]

and for all \( K \in \mathcal{T}_h \)

\[ \int_K \nabla \cdot (u_1 + u^D) = \int_K g. \]

5. Numerical experiments

We set \( \Omega = (0, 1) \times (0, 1) \), \( \sigma = 1 \), and we give the exact pressure \( p = \sin(2\pi x) \sin(2\pi y) \). The velocity is computed from the Darcy’s law, \( g \) is obtained from the divergence of velocity, and the boundary condition \( b \) is taken to be its normal component on the boundary. Fig. 1 depicts error curves for the discontinuous pressure case which are in agreement with theory. In addition, we observe optimal convergence in the \( L^2 \) norm for \( u_1 \). Mimicking [4] in the context of Darcy model, i.e., stabilizing Galerkin method through a pressure projection only, convergence is lost. It seems that consistency is a necessary condition to recover convergence (see Fig. 1). Similar conclusions arise in the continuous case as well. Finally, Table 1 verifies the local mass conservation property.
