#### Abstract

We formulate a strong positivity conjecture on characters afforded by the Alvis-Curtis dual of the intersection cohomology of Deligne-Lusztig varieties. This conjecture provides a powerful tool to determine decomposition numbers of unipotent $\ell$-blocks of finite reductive groups.

## R É S U M É

Nous formulons une conjecture de positivité sur le dual d'Alvis-Curtis du caractère obtenu à partir de la cohomologie d'intersection d'une variété de Deligne-Lusztig. Cette conjecture se révèle être un outil puissant pour déterminer les nombres de décompositions des $\ell$-blocs unipotents des groupes réductifs finis.

## 1. Deligne-Lusztig varieties

Let $\mathbf{G}$ be a connected reductive linear algebraic group over an algebraically closed field of positive characteristic $p$, and $F: \mathbf{G} \rightarrow \mathbf{G}$ be a Steinberg endomorphism. There exists a positive integer $\delta$ such that $F^{\delta}$ defines a split $\mathbb{F}_{q^{\delta}}$-structure on $\mathbf{G}$ (with $q \in \mathbb{R}_{+}$), and we will choose $\delta$ minimal for this property. We set $G:=\mathbf{G}^{F}$, the finite group of fixed points.

We fix a pair ( $\mathbf{T}, \mathbf{B}$ ) consisting of a maximal torus contained in a Borel subgroup of $\mathbf{G}$, both of which are assumed to be $F$-stable. We denote by $W$ the Weyl group of $\mathbf{G}$, and by $S$ the set of simple reflections in $W$ associated with $\mathbf{B}$. Then $F^{\delta}$ acts trivially on $W$.

Following Deligne and Lusztig, there exists a variety $\mathrm{X}(w)$, for any $w \in W$, endowed with an action of $G \times\left\langle F^{\delta}\right\rangle$, whose $\ell$-adic cohomology gives rise to the so-called unipotent representations of $G$.

[^0]
### 1.1. Basic sets for finite reductive groups

Let $\ell$ be a prime number and ( $K, \mathcal{O}, k$ ) be an $\ell$-modular system. We assume that it is large enough for all the finite groups encountered. Furthermore, since we will be working with $\ell$-adic cohomology, we will assume throughout this note that $K$ is a finite extension of $\mathbb{Q}_{\ell}$.

Let $H$ be a finite group. Representations of $H$ will always be assumed to be finite-dimensional. Recall that every projective kH -module lifts to a representation of $H$ over $K$. The character afforded by such a representation will be referred to as a projective character. Integral linear combinations of projective characters will be called virtual projective characters.

Throughout this paper, we shall make the following assumptions on $\ell$ :

- $\ell \neq p$ (non-defining characteristic),
- $\ell$ is good for $\mathbf{G}$ and $\ell \nmid\left|\left(Z(\mathbf{G}) / Z(\mathbf{G})^{\circ}\right)^{F}\right|$.

In this situation, the unipotent characters lying in a given unipotent $\ell$-block of $G$ form a basic set of this block $[6,5]$. Consequently, the restriction of the decomposition matrix of the block to the unipotent characters is invertible. In particular, every (virtual) unipotent character is a virtual projective character, up to adding and removing some non-unipotent characters.

### 1.2. A positivity conjecture

Let $D_{G}$ denote the Alvis-Curtis duality, with the convention that if $\rho$ is a cuspidal unipotent character, then $D_{G}(\rho)=$ $(-1)^{\mathrm{rk}_{F}(\mathbf{G})} \rho$ where $\mathrm{rk}_{F}(\mathbf{G})=|S / F|$ is the $F$-semisimple rank of $\mathbf{G}$. For $w \in W$, we denote by $I H^{i}(\overline{\mathrm{X}}(w))$ the $i$ th intersection cohomology group of the Zariski closure $\overline{\mathrm{X}}(w)$ of $\mathrm{X}(w)$ in $\mathbf{G} / \mathbf{B}$, with coefficients in the trivial local system. We define $Q_{w}$ to be the restriction to $G$ of the virtual character

$$
\sum_{i \in \mathbb{Z}}(-1)^{i}\left[D_{G}\left(I H^{i}(\overline{\mathrm{X}}(w))\right)\right]
$$

and by $Q_{w}[\lambda]$ the generalized $\lambda$-eigenspace of $F^{\delta}$ for $\lambda \in k^{\times}$. By [11, Thm. 3.8, 5.11.4 and 6.8.6] this character can be computed using almost characters together with values of characters of the Iwahori-Hecke algebra associated with $W$ on the Kazhdan-Lusztig basis.

Lusztig proved [11, Prop. 6.9 and 6.10] that up to a global sign, $Q_{w}$ (and even $Q_{w}[\lambda]$ ) is always a nonnegative linear combination of unipotent characters (note that the assumption on $q$ can be removed by [2, Cor. 3.3.22]). The sign is given by the $a$-value $a(w)$ of the two-sided cell in which $w$ lies.

Proposition 1.1 (Lusztig). For all $w \in W$ and all $\lambda \in k^{\times},(-1)^{a(w)} Q_{w}[\lambda]$ is a sum of unipotent characters.
Unipotent characters are only the unipotent part of virtual projective characters in general. We conjecture that the modular analogue of Proposition 1.1 should hold in general, that is that $Q_{w}$ is actually a proper projective character whenever $\ell$ is not too small.

Conjecture 1.2. Under the assumption on $\ell$ in Section 1.1, for all $w \in W$ and all $\lambda \in k^{\times},(-1)^{a(w)} Q_{w}[\lambda]$ is the unipotent part of a projective character.

This conjecture has been checked on many decomposition matrices, including the unipotent blocks with cyclic defect groups for exceptional groups, and the matrices that are determined in $[3,4]$. We will give some examples in Section 3.

Example 1. The closure of the Deligne-Lusztig variety $\mathrm{X}\left(w_{0}\right)$ associated with the longest element $w_{0}$ of $W$ is smooth and equal to $\mathbf{G} / \mathbf{B}$. Therefore, its intersection cohomology $I H^{\bullet}\left(\overline{\mathrm{X}}\left(w_{0}\right)\right)$ consists of copies of the trivial representation in degrees of a given parity. Since $a\left(w_{0}\right)=\ell\left(w_{0}\right)$, then $(-1)^{a\left(w_{0}\right)} Q_{w_{0}}$ is a nonnegative multiple of the Steinberg character. On the other hand, the Steinberg character is the unipotent part of a unique projective indecomposable module (given by a summand of a Gelfand-Graev module) and therefore the conjecture holds for $w_{0}$.

## 2. Applications

In this section, we explain how to deduce properties of decomposition matrices using Conjecture 1.2.

### 2.1. Families of simple unipotent modules

Following [11, §5], we denote by $\leqslant_{\mathrm{LR}}$ the partial order on two-sided cells of $W$. Recall that to each cell $\Gamma$ corresponds a two-sided ideal $I_{\leqslant \Gamma}:=\operatorname{span}_{\mathbb{Q}}\left\{C_{w \mid v=1} \mid w \leqslant L R \quad \Gamma\right\}$ of the group algebra $\mathbb{Q} W$, where $\left(C_{w}\right)_{w \in W}$ is the Kazhdan-Lusztig basis of the corresponding Hecke-algebra with parameter $v$. Moreover, given $\chi \in \operatorname{Irr} W$, there is a unique two-sided cell $\Gamma_{\chi}$ such that $\chi$ occurs in $I_{\leqslant \Gamma_{\chi}} / I_{<\Gamma_{\chi}}$. To each two-sided cell $\Gamma$ one can attach a so-called family $\mathcal{F}_{\Gamma}$ of unipotent characters. They are defined as the constituents of $R_{\chi}$ for various $\chi$ such that $\Gamma_{\chi}=\Gamma$. By [11, Thm. 6.17], they form a partition of the set of unipotent characters of $G$.

We can use the characters $Q_{w}$ to define families of simple unipotent $k G$-modules. For each $Q_{w}$ we choose a virtual projective $k G$-module $\widetilde{Q}_{w}$ whose character coincides with $Q_{w}$ up to adding/removing non-unipotent characters. We denote by $\operatorname{Irr}_{\leqslant \Gamma}{\underset{\sim}{\alpha}}_{k} G$ (resp. $\operatorname{Irr}_{<\Gamma} k G$ ) the set of simple unipotent $k G$-modules $N$ such that a projective cover $P_{N}$ occurs in the virtual module $\widetilde{Q}_{w}$ for some $w \leqslant_{\mathrm{LR}} \Gamma$ (resp. $w<_{\mathrm{LR}} \Gamma$ ). We define the family of simple unipotent modules associated with $\Gamma$ as $\operatorname{Irr}_{\Gamma} k G=\operatorname{Irr}_{\leqslant \Gamma} k G \backslash \operatorname{Irr}_{<\Gamma} k G$. Since the regular representation is uniform (see for example [1, Cor. 12.14]), then every indecomposable projective module lying in a unipotent block occurs in some $\widetilde{Q}_{w}$; therefore every simple unipotent module belongs to at least one family. However, it is unclear whether this family is unique in general.

It is conjectured that, for $\ell$ not too small, the $\ell$-modular decomposition matrix of $G$ depends only on the order of $q$ modulo $\ell$. The following proposition gives some evidence toward this conjecture as well as to Geck's conjecture on the unitriangular shape of the decomposition matrix [7, Conj. 3.4].

Proposition 2.1. Let b be a unipotent $\ell$-block of G. Assume that
(i) Conjecture 1.2 holds, and
(ii) $\left|\operatorname{Irr}_{\Gamma} b k G\right|=\left|\mathcal{F}_{\Gamma} \cap \operatorname{Irr} b\right|$ for any two-sided cell $\Gamma$ of $W$.

Then the unipotent part of the decomposition matrix of $b$ has the following shape:

$$
D_{\mathrm{uni}}=\left(\begin{array}{cccc}
D_{\mathcal{F}_{1}} & 0 & \cdots & 0 \\
* & D_{\mathcal{F}_{2}} & \ddots & \vdots \\
\vdots & \ddots & \ddots & 0 \\
* & \cdots & * & D_{\mathcal{F}_{r}}
\end{array}\right)
$$

where $\mathcal{F}_{i}$ runs over the families and where each $D_{\mathcal{F}_{i}}$ is a square matrix of size $\left|\mathcal{F}_{i} \cap \operatorname{Irr} b\right|$. Furthermore, the entries of $D_{\text {uni }}$ are bounded above independently of $q$ and $\ell$.

Proof. Given any simple $k G$-module $N$ in the block, there exists by (ii) a unique two-sided cell $\Gamma$ such that $N \in \operatorname{Irr}_{\Gamma} b k G$ and $P_{N}$ occurs in some $Q_{w}$ for $w \in \Gamma$ (note that $w \nless_{\mathrm{LR}} \Gamma$, otherwise $N$ would belong to a smaller family). Since the matrix of the $Q_{w}$ 's is block triangular with respect to families, the proposition follows from (i).

Remark 1. Assumption (ii) ensures that families define a partition of the set of simple unipotent $k G$-modules. This assumption will hold whenever each unipotent character in the block is a linear combination of the unipotent almost characters cut by the block. This condition can easily be checked on Fourier matrices; for example, it holds whenever $\ell \mid(q \pm 1)$ and $\mathbf{G}$ is exceptional.

### 2.2. Determining decomposition numbers

The bounds on the entries of the decomposition matrix given by the $Q_{w}$ 's are often small enough to determine some of the decomposition numbers. We illustrate this on the principal $\Phi_{2}$-block of the group $\mathrm{F}_{4}(q)$.

Proposition 2.2. Assume that $(q, 6)=1, q \equiv-1(\bmod \ell)$ and $\ell>11$. If Conjecture 1.2 holds then

| $\phi_{9,10}$ | 1 |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\phi_{2,16}^{\prime \prime}$ | 1 | 1 |  |  |  |  |
| $\phi_{2,16}^{\prime}$ | 1 | . | 1 |  |  |  |
| $B_{2}, \varepsilon$ | 2 | . | . |  |  |  |
| $\phi_{1,24}$ | 3 | 2 | 2 | 4 |  |  |

is a submatrix of the $\ell$-modular decomposition matrix of $\mathrm{F}_{4}(q)$. (Here, "." denotes zero entries.)
Proof. By [10], the above matrix is a submatrix of the decomposition matrix of $\mathrm{F}_{4}(q)$, but with undetermined entries $f, g, h, i, j$ in place of the entries larger than 1 , which satisfy $f, h, i \geqslant 2, g \geqslant 4 f-5$ and $j \geqslant 4$. Let $b$ be the block idempotent associated with the principal $\ell$-block of $\mathrm{F}_{4}(q)$. With $w=s_{2} s_{3} s_{2} s_{3} s_{4} s_{3} s_{2} s_{1} s_{3} s_{2} s_{4} s_{3} s_{2} s_{1}$ we have:

$$
b Q_{w}=32 \phi_{9,10}+72 \phi_{2,16}^{\prime \prime}+72 \phi_{2,16}^{\prime}+72 B_{2}, \varepsilon+288 \phi_{1,24}
$$

If we denote by $P_{1}, \ldots, P_{5}$ the unipotent part of the characters of the PIMs corresponding to the last five columns of the decomposition matrix of $\mathrm{F}_{4}(q)$, we can decompose $Q_{w}$ as

$$
b Q_{w}=32 P_{1}+40 P_{2}+40 P_{3}+(72-32 f) P_{4}+(288-32 g-40 h-40 i-(70-32 f) j) P_{5} .
$$

By Conjecture 1.2, the multiplicity of each $P_{k}$ should be nonnegative, that is $72-32 f \geqslant 0$ and $288-32 g-40 h-$ $40 i-(70-32 f) j \geqslant 0$. Since $f \geqslant 2$ the first relation forces $f=2$ (and therefore $g \geqslant 3$ ). The second becomes $288-32 g-40 h-40 i-8 j \geqslant 0$. Since $288=32 \times 3+40 \times 2+40 \times 2+8 \times 4$ is the minimal value that the expression $32 g+40 h+40 i+8 j$ can take, we deduce that $h=i=2, g=3$ and $j=4$.

## 3. Further examples

### 3.1. A cuspidal module in the unitary group

We give here a non-trivial example for $\mathrm{SU}_{n}(q)$ where Conjecture 1.2 holds. The key point is to find a formula for the corresponding Kazhdan-Lusztig basis element in terms of well-identified elements of $W$. This is done using the geometric description of Kazhdan-Lusztig polynomials. The approach given below could be adapted to other groups, even when the corresponding Schubert variety is no longer smooth, using Bott-Samelson varieties instead.

Recall that the set of unipotent characters of $\mathrm{SU}_{n}(q)$ is parameterized by partitions of $n$. Given such a partition $\lambda$, we denote by $\rho_{\lambda}$ (resp. $\chi_{\lambda}$ ) the corresponding unipotent character (resp. character of $\mathfrak{S}_{n}$ ), with the convention that $\rho_{1^{n}}$ is the Steinberg character.

Proposition 3.1. Let $\ell>n$ be a prime dividing $q+1$. Then Conjecture 1.2 holds for $\mathrm{SU}_{n}(q)$ and $w=s_{1} w_{0} \in \mathfrak{S}_{n}$. Furthermore,

$$
\frac{(-1)^{a(w)}}{(n-1)!} Q_{w}=\rho_{21^{n-2}}+(n-1) \rho_{1^{n}}
$$

is the unipotent part of a projective indecomposable $k \mathrm{SU}_{n}(q)$-module.
Here $w_{0}$ is the longest element of $W \cong \mathfrak{S}_{n}$ and $s_{i}$ is the transposition $(i, i+1)$.
Proof. Let $w_{I}$ denote the longest element of the parabolic subgroup of $W$ generated by $s_{2}, \ldots, s_{n-2}$. Using the fact that the Schubert varieties associated with $w_{0}, w_{1}$ and $s_{1} w_{0}$ are smooth, one finds the following relation between the corresponding Kazhdan-Lusztig basis elements:

$$
C_{s_{1} w_{0} \mid v=1}=-C_{w_{0} \mid v=1}+s_{1} s_{2} \cdots s_{n-1} C_{w_{I} \mid v=1} .
$$

Given a partition $\lambda$, the multiplicity of $\rho_{\lambda}$ in $Q_{w}$ is $(-1)^{A(\lambda)} \chi_{\lambda}\left(C_{w \mid v=1} w_{0}\right)$, where $A(\lambda)$ denotes the degree in $q$ of the degree polynomial of the unipotent character $\rho_{\lambda}$. For $w=s_{1} w_{0}$ the value of $\chi_{\lambda}$ can be computed easily from the above formula.

### 3.2. Groups of small rank

We finish by computing for several groups $G$ of small rank the contribution to the principal $\ell$-block $b$ by various $Q_{w}$ 's. In the table below, we give in the second column the minimal integer $d$ such that $\ell \mid\left(q^{d}-1\right)$, and in the last column the decomposition of $Q_{w}$ in the basis of projective indecomposable modules which is obtained from the decomposition matrices in $[8,3,4,9]$. Note however that this might change when $\ell$ is small as the decomposition matrix will change (see for example $\mathrm{G}_{2}(4)$ with $\ell=5$ ). In any case, $Q_{w}$ remains the unipotent part of a proper projective character. Our notation for the unipotent characters is as in the cited sources.

| $G$ | $d$ | $w$ | $\lambda$ | $b Q_{w}[\lambda]$ |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{Sp}_{6}(q)$ | 2 | $s_{1} s_{2} s_{1} s_{2} s_{3}$ | 1 | $3\left(\rho_{1,1^{2}}+\mathrm{St}\right)+\left(B_{2}, 1^{2}+2 \mathrm{St}\right)+\left(\rho_{1^{3},-}+3 \mathrm{St}\right)$ |
| $\mathrm{G}_{2}(q)$ | 2 | $s_{1} s_{2}$ | -1 | $G_{2}[-1]+2 \mathrm{St}$ |
| ${ }^{3} \mathrm{D}_{4}(q)$ | 6 | $s_{1} s_{2} s_{3} s_{2}$ | 1 | $2\left(\phi_{2,2}+\phi_{1,3}^{\prime}+\mathrm{St}\right)+2\left({ }^{3} \mathrm{D}_{4}[-1]+2 \mathrm{St}\right)$ |
| $\mathrm{SU}_{6}(q)$ | 2 | $s_{1} s_{3} s_{4} s_{3}$ | 1 | $2\left(\rho_{321}+2 \rho_{2^{3}}+2 \rho_{31^{3}}+2 \rho_{2^{2} 1^{2}}+2 \rho_{21^{4}}+6 \rho_{1^{6}}\right)$ |
| $\mathrm{F}_{4}(q)$ | 12 | $s_{1} s_{2} s_{1} s_{3} s_{2} s_{1} s_{3} s_{2} s_{4} s_{3} s_{2} s_{3}$ | $\zeta_{12}^{5}$ | $2 F_{4}[\theta]+20 B_{2}, \mathrm{St}+4 \mathrm{St}$ |
|  |  |  | $\zeta_{12}^{4}$ | $4 F_{4}[\theta]+F_{4}[\mathrm{i}]+11 B_{2}, \mathrm{St}+10 \mathrm{St}$ |

One can even construct larger examples for which the conjecture holds. We give below five examples of computations of $Q_{w}$ in $\mathrm{SU}_{10}(q)$ for $\ell \mid(q+1)$. When $\ell>17$, we can use [4, Thm. 6.2] to decompose them on the basis of projective indecomposable modules. It turns out that at least four of them are (up to a scalar) the character of a projective indecomposable module.

| $w$ | $Q_{w}$ |
| :---: | :---: |
| $s_{1} s_{3} s_{4} s_{3} s_{5} s_{4} s_{3} s_{6} s_{5} s_{4} s_{3} s_{7} s_{6} s_{5} s_{4} s_{3} s_{9} s_{8} s_{7} s_{6} s_{5} s_{4} s_{3}$ | $1440 \Psi_{321^{5}}$ |
| $s_{1} S_{2} s_{1} S_{4} S_{5} S_{4} S_{6} S_{5} S_{4} S_{7} S_{6} S_{5} S_{4} S_{8} S_{7} S_{6} S_{5} S_{4}$ | $96 \Psi_{32^{2} 1^{3}}$ |
| $s_{5} s_{4} S_{3} s_{2} s_{1} s_{4} s_{3} s_{2} s_{4} S_{3} s_{4} s_{9} s_{8} s_{7} s_{9} s_{8} s_{9}$ | $576 \Psi_{32^{3} 1}$ |
| $s_{1} s_{2} s_{1} s_{4} s_{5} s_{4} s_{6} s_{5} s_{4} s_{7} s_{6} s_{5} s_{4} s_{9}$ | $96 \Psi_{32}{ }^{2} 1^{2}$ |
| $s_{2} s_{1} s_{2} s_{3} s_{7} s_{6} s_{5} s_{7} s_{6} s_{7} s_{9}$ | $16\left(\Psi_{4321}+(1-\alpha) \Psi_{32^{3} 1}+\beta \Psi_{2^{4} 1^{2}}\right)$ |

Here $\alpha, \beta \in\{0,1\}$ are as in [4, Thm. 6.2]

## Acknowledgements

We would like to thank Jean Michel for helping us to compute the characters of the modules $Q_{w}$ in Chevie [12], especially for $\mathrm{SU}_{10}(q)$.
