Probability theory

On the mixing time of the flip walk on triangulations of the sphere

Flips sur les triangulations de la sphère : une borne inférieure pour le temps de mélange

Thomas Budzinski

ENS Paris and Université Paris-Saclay, France

1. Introduction

Much attention has been given recently to the study of large uniform triangulations of the sphere. Historically, these triangulations have been first considered by physicists as a discrete model for quantum gravity. Before the introduction of more direct tools (bijection with trees or peeling process), the first simulations [6,7] were made using a Monte-Carlo method based on flips of triangulations.

More precisely, for all $n \geq 3$, let $\mathcal{T}_n$ be the set of rooted type-I triangulations of the sphere with $n$ vertices (that is, triangulations that may contain loops and multiple edges, equipped with a distinguished oriented edge). If $t$ is a triangulation, we write $V(t)$ for the set of its vertices and $E(t)$ for the set of its edges. If $t \in \mathcal{T}_n$ and $e \in E(t)$, we write $\text{flip}(t, e)$ for the
triangulation obtained by removing the edge $e$ from $t$ and drawing the other diagonal of the face of degree 4 that appears. We say that $\text{flip}(t, e)$ is obtained from $t$ by flipping the edge $e$ (cf. Fig. 1). Note that it is possible to flip a loop and to flip the root edge. The only case in which an edge cannot be flipped is if both of its sides are adjacent to the same face like the edge $e_2$ in Fig. 1. In this case, $\text{flip}(t, e) = t$. Note that there is a natural bijection between $E(t)$ and $E(\text{flip}(t, e))$. When there is no ambiguity, we shall sometimes treat an element of one of these two sets as if it belonged to the other.

The graph of triangulations of the sphere in which two triangulations are related if one can pass from one to the other by flipping an edge has already been studied in the type-III setting (that is, triangulations with neither loops nor multiple edges): it is connected [15] and its diameter is linear in $n$ [8]. We extend these results to our setup in Lemma 12.

We define a Markov chain $(T_n(k))_{k \geq 0}$ on $\mathcal{T}_n$ as follows: conditionally on $(T_n(0), \ldots, T_n(k))$, let $e_k$ be a uniformly chosen edge of $T_n(k)$. We take $T_n(k + 1) = \text{flip}(T_n(k), e_k)$. It is easy to see that the uniform measure on $\mathcal{T}_n$ is reversible, thus stationary for $(T_n(k))_{k \geq 0}$, so this Markov chain will converge to the uniform distribution (the irreducibility is guaranteed by the connectedness results described above and the aperiodicity by the possible existence of non-flippable edges). It is then natural to estimate the mixing time of $(T_n(k))_{k \geq 0}$ (see Chapter 4.5 of [12] for a proper definition of the mixing time). Our theorem provides a lower bound.

**Theorem 1.** There is a constant $c > 0$ such that for all $n \geq 3$ the mixing time of the Markov chain $(T_n(k))_{k \geq 0}$ is at least $cn^{5/4}$.

Mixing times for other types of flip chains have also been investigated. For triangulations of a convex $n$-gon without inner vertices, it is known that the mixing time is polynomial and at least of order $n^{3/2}$ (see [13,14]). In particular, our proof was partly inspired by the proof of the lower bound in [14]. Finally, see [3] for estimates on the mixing time of the flip walk on lattice triangulations, that is, triangulations whose vertices are points on a lattice and with Boltzmann weights depending on the total length of their edges.

The strategy of our proof is as follows: we start with two independent uniform triangulations with a boundary of length 1 and $\frac{n}{2}$ inner vertices and glue them together along their boundaries. We obtain a triangulation of the sphere with a cycle of length 1 such that half of the vertices lie on each side of this cycle. We then start our Markov chain from this triangulation and discover one of the two sides of the cycle gradually by a peeling procedure. By using the estimates of Curien and Le Gall [5] and a result of Krikun about separating cycles in the UIPT [9], we show that after $o(n^{5/4})$ flips, with high probability, the triangulation still has a cycle of length $o(n^{1/4})$, on each side of which lies a proportion at least $\frac{1}{2}$ of the vertices. But by a result of Le Gall and Paulin [11], this is not the case in a uniform triangulation (this is the discrete counterpart of the homeomorphism of the Brownian map to the sphere), which shows that a time $o(n^{5/4})$ is not enough to approach the uniform distribution.

**2. Combinatorial preliminaries and couplings**

For all $n \geq 3$, we recall that $\mathcal{T}_n$ is the set of rooted type-I triangulations of the sphere with $n$ vertices. For $n \geq 0$ and $p \geq 1$, we also write $\mathcal{T}_{n,p}$ for the set of triangulations with a boundary of length $p$ and $n$ inner vertices, that is, planar maps with $n + p$ vertices in which all faces are triangles except one called the outer face whose boundary is a simple cycle of length $p$, equipped with a root edge such that the outer face touches the root edge on its right. We will sometimes refer to $n$ and $p$ as the volume and the perimeter of the triangulation.

The number of triangulations with fixed volume and perimeter can be computed by a result of Krikun. Here is a special case of the main theorem of [10] (the full theorem deals with triangulations with $r + 1$ boundaries but we only use the case $r = 0$):

$$\# \mathcal{T}_{n,p} = \frac{p(2p)!}{(p!)^2} \cdot \frac{4^{n-1}(2p + 3n - 5)!!}{n!(2p + n - 1)!!} \sim_{n \to +\infty} C(p) \lambda_e^n n^{-5/2},$$

where $\lambda_e = \frac{1}{12\sqrt{3}}$ and $C(p) = \frac{3^p - p2p!}{4\sqrt{2}(n!p!)^2}$. In particular, a triangulation of the sphere with $n$ vertices is equivalent after a root transformation to a triangulation with a boundary of length 1 and $n - 1$ inner vertices (more precisely we need to duplicate the root edge, add a loop inbetween and root the map at this new loop, see for example Fig. 2 in [4]), so...
Let \( p_n = o(\sqrt{n}) \) and \( r_n = o(n^{1/4}) \) with \( p_n = o(r_n^2) \). Then there are \( r'_n = o(r_n) \) and couplings between \( T_{n,p_n} \) and \( T_\infty \) such that
\[
\mathbb{P} \left( B_{r'_n}(T_\infty) \setminus B^*_n(T_\infty) \subset B^*_n(T_{n,p_n}) \right) \to 1.
\]

The above lemma follows from the following. There is a cycle \( \gamma' \) of length \( p_n \) around the root of \( T_\infty \) that lies inside of its hull of radius \( r'_n \) and a cycle \( \gamma \) in \( T_{n,p_n} \) that stays at distance at most \( r_n \) from its boundary, such that the part of the hull of radius \( r_n \) of \( T_\infty \) that lies outside of \( \gamma' \) is isomorphic to the part of \( T_{n,p_n} \) that lies between its boundary and \( \gamma \) (see Fig. 2).

**Proof.** We start by describing a coupling between the UIPT and the UIPT with a boundary of length \( p_n \), which we write \( T_{\infty,p_n} \). We consider the peeling by layers \( \mathcal{L} \) of the UIPT (see section 4.1 of [5]) and we write \( \tau_{p_n} \) for the first time at which the perimeter of the discovered region is equal to \( p_n \) (note that this time is always finite since the perimeter can increase by at most 1 at each peeling step). By the spatial Markov property of the UIPT, the part that is still unknown at time \( \tau_{p_n} \)
has the distribution of $T_{\infty,p_n}$. Moreover, by the results of Curien and Le Gall (Theorem 1 of [5]), since $p_n = o(r_n^2)$, we have $\tau_{p_n} = o(r_n^4)$. By using Proposition 9 of [5] (more precisely the convergence of $H$), we obtain that the smallest hull of $T_{\infty}$ containing $t_{p_n}^\infty(T_{\infty})$ has radius $o(r_n)$ in probability. Hence, our result holds if we replace $T_{n,p_n}$ by $T_{\infty,p_n}$.

Hence, it is enough to prove that there are couplings between $T_{\infty,p_n}$ and $T_{n,p_n}$ such that

$$\mathbb{P}(B_n^*(T_{n,p_n}) = B_n^*(T_{\infty,p_n})) \xrightarrow{n \to +\infty} 1.$$  

The proof relies on asymptotic enumeration results and is essentially the same as that of Proposition 12 of [2]: by using the above coupling of $T_{\infty,p_n}$ and $T_{\infty}$, we can show that

$$\left( \frac{1}{\sqrt{n}} \partial B_n^*(T_{\infty,p_n}), \frac{1}{n} |B_n^*(T_{\infty,p_n})| \right) \xrightarrow{(P)} (0, 0).$$  

Moreover, if $q_n = o(\sqrt{n})$ and $v_n = o(n)$ and if $t_n$ is a triangulation with two holes of perimeters $p_n$ and $q_n$ (rooted on the boundary of the $p_n$-gon) and $v_n$ vertices that is a possible value of $B_n^*(T_{\infty,p_n})$ for all $n \geq 0$, then

$$\mathbb{P}(B_n^*(T_{n,p_n}) = t_n) \xrightarrow{n \to +\infty} 1$$

by the enumeration results, and we can conclude as in Proposition 12 of [2].

We will also need another coupling lemma where we do not compare hulls of a fixed radius, but rather the parts of triangulations that have been discovered after a fixed number of peeling steps.

**Lemma 2.** Let $j_n = o(n^{3/4})$, and let $\tau^\infty$ be a peeling algorithm. Then there are couplings between $T_n$ and $T_{\infty}$ such that

$$\mathbb{P}(\tau^\infty(T_n) = \tau^\infty(T_{\infty})) \xrightarrow{n \to +\infty} 1.$$  

**Proof.** We write $P_{\infty}(j)$ and $V_{\infty}(j)$ for respectively the perimeter and volume of $\tau^\infty(T_{\infty})$. By the results of [5], we have the convergences

$$\frac{1}{\sqrt{n}} \sup_{0 \leq j \leq j_n} P_{\infty}(j) \xrightarrow{n \to +\infty} 0 \quad \text{and} \quad \frac{1}{n} \sup_{0 \leq j \leq j_n} V_{\infty}(j) \xrightarrow{n \to +\infty} 0$$

in probability, so there are $p_n = o(\sqrt{n})$ and $v_n = o(n)$ such that

$$\mathbb{P}(P_{\infty}(j_n) \leq p_n \text{ and } V_{\infty}(j_n) \leq v_n) \to 1.$$  

But by the enumeration results (1), (2) and by (3), if $t_n$ is a rooted triangulation with perimeter at most $p_n$ and volume at most $v_n$, we have

$$\mathbb{P}(\tau^\infty(T_n) = t_n) \xrightarrow{n \to +\infty} 1.$$  

As in Proposition 12 of [2], this proves that the total variation distance between the distributions of $\tau^\infty_j(T_n)$ and $\tau^\infty_j(T_{\infty})$ goes to $0$ as $n \to +\infty$, which proves our claim and the lemma.

By combining this last lemma and the estimates (4), we immediately obtain estimates about the peeling process on finite uniform triangulations. We write $P_n(j)$ and $V_n(j)$ for the perimeter and volume of $\tau^\infty_j(T_n)$.

**Corollary 3.** Let $j_n = o(n^{3/4})$. Then we have the following convergences in probability:

$$\frac{1}{\sqrt{n}} \sup_{0 \leq j \leq j_n} P_n(j) \xrightarrow{n \to +\infty} 0 \quad \text{and} \quad \frac{1}{n} \sup_{0 \leq j \leq j_n} V_n(j) \xrightarrow{n \to +\infty} 0.$$  

Finally, we show a result about small cycles surrounding the boundary in uniform triangulations with a perimeter small enough compared to their volume.

**Lemma 4.** Let $p_n = o(\sqrt{n})$ and $r_n = o(n^{1/4})$ be such that $p_n = o(r_n^2)$. Then for all $\epsilon > 0$, the probability of the event

"there is a cycle $\gamma$ in $T_{n,p_n}$ of length at most $r_n$ such that the part of $T_{n,p_n}$ lying between $\partial T_{n,p_n}$ and $\gamma$ contains at most $\epsilon n$ vertices"

goes to $1$ as $n \to +\infty$.
This result is not surprising. In the context of quadrangulations with a non-simple boundary, it is a consequence of the convergence of quadrangulations with boundaries to Brownian disks, see [1]. However, no scaling limit result is known yet for triangulations with boundaries. Hence, we will rely on a result of Krikun about small cycles in the UIPT, which we will combine with Lemma 1. Here is a restatement of Theorem 6 of [9].

**Theorem 2 (Krikun).** For all $\varepsilon > 0$, there is a constant $C$ such that, for all $r$, with probability at least $1 - \varepsilon$, there is a cycle of length at most $Cr$ surrounding $B^*_n(T_{\infty})$ and lying in $B^*_n(T_{\infty})$.

Note that Krikun deals with type-II triangulations, i.e. with multiple edges but no loops, but the decomposition used in [9] is still valid and even a bit simpler in the type-I setting, see [4]. The fact that the cycle stays in $B^*_n(T_{\infty})$ is not in the statement of the theorem in [9], but it is immediate from its proof.

**Proof of Lemma 4.** By Lemma 1 it is possible to couple $T_{\infty}$ with $T_{n,p_n}$ in such a way that
\[
\mathbb{P}(B_r^*(T_{\infty}) \cap B_r^*(T_{n,p_n})) \xrightarrow{n \to +\infty} 1,
\] where $r_n = o(r_n)$. On the other hand, by Theorem 2, we have
\[
\mathbb{P}\left(\text{there is a cycle } \gamma \text{ of length } \leq r_n \text{ in } B^*_n(T_{\infty}) \text{ that surrounds } B^*_n(T_{n,p_n})\right) \xrightarrow{n \to +\infty} 1.
\]

For $n$ large enough, we have $r_n \geq 2r_n$, so if such a $\gamma$ exists, then it must stay in $B^*_n(T_{\infty})$. Since $r_n = o(n^{1/4})$, the probability that the number of vertices lying inside of $\gamma$ is greater than $\varepsilon n$ goes to 0 by Theorem 2 of [5]. But, if the event of (5) holds and if such a cycle exists in $T_{\infty}$, then in $T_{n,p_n}$ there is a cycle $\gamma'$ of length at most $r_n$, such that the part of $T_{n,p_n}$ lying between $\partial T_{n,p_n}$ and $\gamma$ contains at most $\varepsilon n$ vertices. \(\square\)

3. **Proof of Theorem 1**

Our main task will be to prove the following proposition.

**Proposition 5.** Let $k_n = o(n^{3/4})$. Then there are $t_n \in \mathcal{S}_n$ and $\ell_n = o(n^{1/4})$ such that conditionally on $T_n(0) = t_n$, the probability that there is a cycle of length at most $\ell_n$ that separates $T_n(k_n)$ in two parts of volume at least $\frac{\ell}{4}$ goes to 1 as $n \to +\infty$.

We first define the initial triangulation $T_n(0)$ we will be interested in: let $T^1_n(0)$ and $T^2_n(0)$ be two independent uniform triangulations with a boundary of length 1 and with respectively $\lceil \frac{n-1}{2} \rceil$ and $\lceil \frac{n-1}{2} \rceil$ inner vertices. We write $T_n(0)$ for the triangulation obtained by gluing together the boundaries of $T^1_n(0)$ and $T^2_n(0)$.

We will now perform an exploration of the triangulation while it gets flipped: the part $T^1_n$ will be considered as the “discovered” part and $T^2_n$ as the “unknown” part of the map. More precisely, we define by induction $T^1_{n,k}(k)$ and $T^2_{n,k}(k)$ such that $T^1_n(k)$ is obtained by gluing together the boundaries of $T^1_{n,k}(k)$ and $T^2_{n,k}(k)$. The two triangulations for $k = 0$ are defined above. Now assume we have constructed $T^1_{n,k}(k)$ and $T^2_{n,k}(k)$. Then:

- if $e_k$ lies inside of $T^1_{n,k}(k)$ then $T^1_{n,k}(k + 1) = \text{flip}(T^1_{n,k}(k), e_k)$ and $T^2_{n,k}(k + 1) = T^2_{n,k}(k)$,
- if $e_k$ lies inside of $T^2_{n,k}(k)$ then $T^2_{n,k}(k + 1) = T^2_{n,k}(k)$ and $T^1_{n,k}(k + 1) = \text{flip}(T^2_{n,k}(k), e_k)$,
- if $e_k \in \partial T^1_{n,k}(k)$, we write $f_k$ for the face of $T^2_{n,k}(k)$ that is adjacent to $e_k$, and we let $T^2_{n,k}(k + 1)$ be the connected component of $T^2_{n,k}(k) \setminus f_k$ with the largest volume and $T^1_{n,k}(k + 1) = \text{flip}(T^2_{n,k}(k), T^2_{n,k}(k + 1), e_k)$.

We now set $\tilde{T}_n(k) = |\partial T^1_{n,k}(k)|$ and $\tilde{V}_n(k) = \big|\mathbb{V}(T^1_{n,k}(k))\big| - \big|\mathbb{V}(T^1_{n,k}(0))\big| + 1$. Note that $\tilde{V}_n(k)$ is nondecreasing in $k$.

For $k \geq 0$, we define a random variable $e^*_k \in E(T^1_{n,k}(k)) \cup \{\star\}$, where $\star$ is an additional state corresponding to all the edges not in $E(T^1_{n,k}(k))$, as follows: if $e_k$ lies inside or on the boundary of $T^1_{n,k}(k)$, then $e^*_k = e_k$, and if not then $e^*_k = \star$. We also define $\mathcal{F}_k$ as the $\sigma$-algebra generated by the variables $(T^1_{n,k}(i))_{0 \leq i \leq k}$ and $(e^*_k)_{0 \leq i \leq k-1}$.

**Lemma 6.** For all $k$, conditionally on $\mathcal{F}_k$, the triangulation $T^2_{n,k}(k)$ is a uniform triangulation with a boundary of length $\tilde{T}_n(k)$ and $\lceil \frac{n+1}{2} \rceil - \tilde{V}_n(k)$ inner vertices.

**Proof.** We prove the lemma by induction on $k$. For $k = 0$ it is obvious by the definition of $T^2_{n,0}(0)$. Let $k \geq 0$ be such that the lemma holds for $k$.

- If $e^*_k$ lies inside $T^1_{n,k}(k)$, the result follows from the fact that $T^2_{n,k}(k) = T^2_{n,k}(k + 1)$ and that conditionally on $\mathcal{F}_k$, the triangulation $T^2_{n,k}(k)$ is independent of $e^*_k$. 

Let $e_k^* = \ast$, it follows from the invariance of the uniform measure on $\mathcal{B}_{n,p}$ under flipping of a uniform edge among those which do not lie on the boundary.

If $e_k^* \in \partial T_n^2(k)$, this is a standard peeling step: by invariance under rooting of a uniform triangulation with fixed perimeter and volume, conditionally on $\mathcal{F}_k$ and $e_k$, the triangulation $T_n^2(k)$ rooted at $e_k$ is uniform. Hence, if the third vertex of the face $f_k$ of $T_n^2(k)$ adjacent to $e_k$ lies inside of $T_n^2(k)$, the remaining part of $T_n^2(k)$ is a uniform triangulation with a boundary of length $P_n(k) + 1$ and $\lceil \frac{2n-1}{3} \rceil - V_n(k) - 1$ inner vertices. If the third vertex of $f_k$ lies on $\partial T_n^2(k)$, then the face $f_k$ separates $T_n^2(k)$ in two independent uniform triangulations with fixed perimeters and volumes, and the lemma follows.

We now define the stopping times $\tau_j$ as the times at which the flipped edge lies on the boundary of the unknown part of the map, that is, the times $k$ at which we discover new parts of $T_n^2(k)$: we set $\tau_0 = -1$ and $\tau_{j+1} = \inf \{ k > \tau_j | e_k \in \partial T_n^2(k) \}$ for $j \geq 0$. We also write $P_n(j) = \overline{P}_n(\tau_j + 1)$ and $V_n(j) = \overline{V}_n(\tau_j + 1)$.

Then Lemma 6 shows that $(P_n, V_n)$ is a Markov chain with the same transitions as the perimeter and volume processes associated with the peeling process of a uniform triangulation with a boundary of length 1 and $\lceil \frac{n-1}{2} \rceil$ inner vertices. Hence, Corollary 3 provides estimates for this process. Our next lemma will allow us to estimate the times $\tau_j$.

**Lemma 7.** Let $k_0 = o(n^{5/4})$. Then for all $\varepsilon > 0$, we have

$$\mathbb{P}(\tau_{\varepsilon n^{5/4}} > k_0) \longrightarrow 1.$$

**Proof.** Conditionally on $P_n$, the variables $\tau_{j+1} - \tau_j$ are independent geometric variables with respective parameters $\frac{P_n(j)}{n}$. Hence, $\tau_{\varepsilon n^{5/4}}$ dominates the sum $S_n$ of $\varepsilon n^{3/4}$ i.i.d. geometric variables with parameter $Q_n = \frac{1}{n} \max_{0 \leq j \leq \varepsilon n^{3/4}} P_n(j)$. We have

$$\mathbb{E}[S_n | P_n] = \varepsilon n^{3/4} Q_n = \varepsilon n^{5/4} \times \frac{1}{\sqrt{n}} \max_{0 \leq j \leq \varepsilon n^{3/4}} P_n(j).$$

By the results of [5], the factor $\frac{1}{\sqrt{n}} \max_{0 \leq j \leq \varepsilon n^{3/4}} P_n(j)$ converges in distribution, so $\frac{\mathbb{E}[S_n | P_n]}{k_0} \longrightarrow +\infty$ in probability. By the weak law of large numbers, we get $\frac{S_n}{k_0} \longrightarrow +\infty$ in probability so $\frac{\tau_{\varepsilon n^{5/4}}}{k_0} \longrightarrow +\infty$ in probability.

By combining Corollary 3 and Lemma 7, we get the following result.

**Lemma 8.** Let $k_0 = o(n^{5/4})$. Then we have the convergences

$$\frac{1}{\sqrt{n}} \overline{P}_n(k_0) \longrightarrow 0 \quad \text{and} \quad \frac{1}{n} \overline{V}_n(k_0) \longrightarrow 0$$

in probability.

**Proof.** By Lemma 7, there is a deterministic sequence $j_n = o(n^{3/4})$ such that $\mathbb{P}(\tau_{j_n} > k_n) \rightarrow 1$. This means that with probability going to 1 as $n \rightarrow +\infty$ there is $j \leq j_n$ such that $\tau_j < k_n \leq \tau_{j+1}$ so

$$\overline{P}_n(k_0) = P_n(j) \leq \sup_{0 \leq j \leq j_n} P_n(j) \quad \text{and} \quad \overline{V}_n(k_0) = V_n(j) \leq \sup_{0 \leq j \leq j_n} V_n(j).$$

But we know from Corollary 3 that

$$\left( \frac{1}{\sqrt{n}} \sup_{0 \leq j \leq j_n} P_n(j), \frac{1}{n} \sup_{0 \leq j \leq j_n} V_n(j) \right) \xrightarrow{\text{(P)}} 0,$$

which proves Lemma 8.

So $T_n^2(k_0)$ has the distribution of $T_{n/2} - \overline{V}_n(k_0), \overline{P}_n(k_0)$ and there is $p_n = o(\sqrt{n})$ such that

$$\mathbb{P}(\overline{P}_n(k_0) < p_n \text{ and } n/2 - \overline{V}_n(k_0) > \frac{n}{3}) \longrightarrow 1.$$

Let $r_n$ be such that $r_n = o(n^{1/4})$ and $p_n = o(r_n^2)$ (take for example $r_n = n^{1/8} P_n^{1/4}$). By Lemma 4, with probability going to 1 as $n \rightarrow +\infty$, there is a cycle $\gamma$ in $T_n^2(k_0)$ of length at most $r_n$ such that the part of $T_n^2(k_0)$ lying between $\partial T_n^2(k_0)$ and $\gamma$ has volume at most $\frac{r_n}{n}$. Moreover, we have $\overline{V}_n(k_0) = o(n)$ in probability by Lemma 8, so the two parts of $T_n(k_0)$ separated by $\gamma$ both have volume at least $\frac{r_n}{n}$, which proves Proposition 5.
The proof of our main theorem is now easy: let \( \mathcal{T}_n \) be the set of the triangulations \( t \) of the sphere with \( n \) vertices in which there is a cycle of length at most \( c n \) that separates \( t \) in two parts of volume at least \( \frac{n}{4} \). Let also \( k_n = o(n^{5/4}) \). By Proposition 5, we have

\[
\mathbb{P}(T_n(k_n) \in \mathcal{T}_n) \xrightarrow{n \to +\infty} 1.
\]

whereas by Corollary 1.2 of [11], if \( T_n(\infty) \) denotes a uniform variable on \( \mathcal{T}_n \), we have

\[
\mathbb{P}(T_n(\infty) \in \mathcal{T}_n) \xrightarrow{n \to +\infty} 0.
\]

Hence, the total variation distance between the distributions of \( T_n(k_n) \) and \( T_n(\infty) \) goes to 1 as \( n \to +\infty \) so the mixing time is greater than \( k_n \) for \( n \) large enough. Since this is true for any \( k_n = o(n^{5/4}) \), the mixing time must be at least \( cn^{5/4} \) with \( c > 0 \).

We end this paper by a few remarks about our lower bound and an open question.

**Remark 9.** We proved a lower bound on the mixing time in the worst case, but our proof still holds for the mixing time from a typical starting point. We just need to fix \( \varepsilon > 0 \) small, take as initial condition a uniform triangulation \( T_n(0) \) conditioned on \( \left| \partial B_{n^{*1/4}}(T_n(0)) \right| \leq \varepsilon \sqrt{n} \) and \( \frac{n}{3} \leq \left| B_{n^{*1/4}}(T_n(0)) \right| \leq \frac{2n}{3} \) and let \( T_n(0) = B_{n^{*1/4}}(T_n(0)) \). The event on which we condition has probability bounded away from 0 (by the results of [5] and coupling arguments) and after time \( o(n^{5/4}) \) there is still a separating cycle of length \( O((\varepsilon^{-1/2}n^{1/4})) \).

**Remark 10.** Here is a back-of-the-envelope computation that leads us to believe the lower bound we give is sharp if we start from a typical triangulation. The lengths of the geodesics in a uniform triangulation of volume \( n \) are of order \( n^{1/4} \), so if we fix two vertices \( x \) and \( y \) the probability that a flip hits the geodesic from \( x \) to \( y \) is roughly \( n^{-3/4} \). Hence, if we do \( n^{3/4} \) flips, about \( n^{-1/2} \) of them will affect the distance between \( x \) and \( y \). If we believe that this distance evolves roughly like a random walk, it will vary of about \( \sqrt{n^{1/2}} = n^{1/4} \), which shows we are at the right scale. Of course, there are many reasons why this computation seems hard to be made rigorous, but it does not seem to be contradicted by numerical simulations.

Finally, note that even in the simpler case of triangulations of a polygon, the lower bound \( n^{3/2} \) is believed to be sharp but the best known upper bound [13] is only \( n^{5+o(1)} \). In our case we were not even able to prove the following.

**Conjecture 11.** The mixing time of \( (T_n(k))_{k \geq 0} \) is polynomial in \( n \).

**Acknowledgements**

I thank Nicolas Curien for carefully reading earlier versions of this manuscript. I also thank the anonymous referee for his useful comments. I acknowledge the support of ANR Liouville (ANR-15-CE25-0013) and ANR GRAAL (ANR-14-CE25-0014).

**Appendix A. Connectedness of the flip graph for type-I triangulations**

In this appendix, we show that the Markov chain we study is indeed irreducible.

**Lemma 12.** Let \( \mathcal{G}_n \) be the graph whose vertex set is \( \mathcal{T}_n \) and where two triangulations are related if one can pass from one to the other by a flip. Then \( \mathcal{G}_n \) is connected and its diameter is linear in \( n \).

**Proof.** It is proved in [15] that the flip graph for type-III triangulations is connected, and in [8] that its diameter is linear in \( n \). Hence, it is enough to show that any triangulation is connected to a type-III triangulation in \( \mathcal{G}_n \) by a linear number of edges. If \( t \) is a finite triangulation with loops, it contains a minimal loop, that is, a loop dividing the sphere in two parts, one of which contains no loop. By flipping a minimal loop, we delete a loop without to create any new one, so we make the number of loops decrease and we can delete all loops in a linear number of flips. Moreover, if \( t \) contains no loop and there are two edges \( e_1, e_2 \) between the same pair of vertices, then flipping \( e_1 \) does not create any loop or additional multiple edges, so we can also delete all multiple edges in a linear number of flips.
