A NOTE ON 4-DIMENSIONAL HANDLEBODIES

BY

FRANÇOIS LAUDENBACH AND VALENTIN POËNARU

1. Introduction

We prove the following theorem :

THEOREM A. — *Let X^p, Y^p be the following smooth 4-manifolds :*

$$X^p = p \# (S_2 \times D_2), \quad Y^p = p \# (S_1 \times D_3).$$

Consider a diffeomorphism $h : \partial X^p \rightarrow \partial Y^p$ and the smooth closed 4-manifold obtained by gluing X^p and Y^p along $h : X^p \cup_h Y^p$.

$X^p \cup_h Y^p$ is diffeomorphic to S_4 .

Theorem A is clearly equivalent to the following :

THEOREM A'. — *Let X^p be as before, and consider p handles of index 3, attached successively to X^p :*

$$\varphi_3^i : S_2^i \times D_1^i \hookrightarrow \partial (X^p + (\varphi_3^1) + \dots + (\varphi_3^{i-1})),$$

where $S_2^i \times D_1^i = \partial D_3^i \times D_1^i \subset \partial (D_3^i \times D_1^i)$ and $i = 1, \dots, p$.

Assume that $\partial (X^p + (\varphi_3^1) + \dots + (\varphi_3^p)) = S_3$, and consider a handle of index 4 :

$$\varphi_4 : \partial D_4 \xrightarrow{\cong} \partial (X^p + (\varphi_3^1) + \dots + (\varphi_3^p)),$$

attached to $X^p + (\varphi_3^1) + \dots + (\varphi_3^p)$. One has :

$$X^p + (\varphi_3^1) + \dots + (\varphi_3^p) + (\varphi_4) = S_4 \quad (\text{diffeomorphism}).$$

This result implies the following :

COROLLARY B. — *Let X^p be as before, and consider p handles of index 3, attached successively to X^p :*

$$\psi_3^i : S_2^i \times D_1^i \hookrightarrow \partial (X^p + (\psi_3^1) + \dots + (\psi_3^{i-1})) \quad (i = 1, \dots, p).$$

If

$$H_2 (X^p + (\psi_3^1) + \dots + (\psi_3^p), Z) = 0$$

then

$$X^p + (\psi_3^1) + \dots + (\psi_3^p) = D_4 \quad (\text{diffeomorphism}).$$

2. The proof of theorem A

One has « canonical » identifications :

$$(0) \quad \begin{array}{ccc} \partial X^p & \xrightarrow{\alpha} & \\ \approx & \searrow & \\ & & (S_2^1 \times S_1^1) \# \dots \# (S_2^p \times S_1^p) = p \# (S_2 \times S_1), \\ & \nearrow & \\ \partial Y^p & \xrightarrow{\beta} & \end{array}$$

which will be given, once for all. It is obvious that

$$X^p \cup_{\beta^{-1}\alpha} Y^p = S_4.$$

LEMMA 1. — *The following two statements are equivalent :*

(i) $X^p \cup_h Y^p = S_4.$

(ii) *There exist diffeomorphisms $G : X^p \rightarrow X^p, H : Y^p \rightarrow Y^p$, such that :*

$$(1) \quad \beta^{-1} \alpha = (H | \partial Y^p) \circ h \circ (G | \partial X^p).$$

Proof. — If f_1, f_2 are two differentiable embeddings $f_i : Y^p \rightarrow S_4$, it is obvious that the pairs $(S_4, f_1 Y^p), (S_4, f_2 Y^p)$ are diffeomorphic. Hence, if $X^p \cup_h Y^p = S_4 = X^p \cup_{\beta^{-1}\alpha} Y^p$, there exists a diffeomorphism : $X^p \cup_h Y^p \rightarrow X^p \cup_{\beta^{-1}\alpha} Y^p$ sending X^p onto X^p and Y^p onto Y^p . This shows that (i) \Rightarrow (ii).

On the other hand, the equality (1) tells us that G and H can be patched together so as to give diffeomorphism :

$$X^p \cup_h Y^p \leftrightarrow X^p \cup_{\beta^{-1}\alpha} Y^p.$$

Hence (ii) \Rightarrow (i).

REMARK. — The implication (ii) \Rightarrow (i) holds whenever we glue two n -manifolds along their (diffeomorphic) boundaries, while (i) \Rightarrow (ii) is very exceptional.

We consider now $\pi_1 Y^p =$ the free group with p generators, and we remark that, if $i : \partial Y^p \hookrightarrow Y^p$ is the natural inclusion, then :

$$i_* : \pi_1 \partial Y^p \rightarrow \pi_1 Y^p$$

is bijective. Let $\text{Diff } Y^p$ be the group of diffeomorphisms of Y^p and $\text{Aut } (\pi_1 Y^p)$ [resp. $\text{Aut } (\pi_1 \partial Y^p)$] the group of automorphisms of $\pi_1 Y^p$ (resp. $\pi_1 \partial Y^p$). We have a commutative triangle of natural homomorphisms :

LEMMA 2. — *A and B are surjective.*

Proof. — We consider a handle-decomposition, given once for all :

$$(2) \quad Y^p = D_i + (\varphi_1^i) + \dots + (\varphi_p^i)$$

where (φ_1^i) corresponds to the handle $D_1^i \times D_3^i$.

We orient the D_1^i 's and we chose a base-point

$$x_0 \in \partial D_i - \cup_i \text{Image } (\varphi_1^i).$$

The spines $[D_1^i]$ will determine then a basis x^1, \dots, x^p for $\pi = \pi_1 (Y^p, x_0)$.

We define $\Phi_1, \Phi_2, \Phi_3 \in \text{Aut } (\pi)$ by :

- (i) $\Phi_1 (x^l) = x^l$ if $l \neq 1, k$, and $\Phi_1 (x^k) = x^k, \Phi_1 (x^l) = x^l$;
- (ii) $\Phi_2 (x^1) = x^1$ if $l \neq 1, \Phi_2 (x^1) = (x^1)^{-1}$;
- (iii) $\Phi_3 (x^1) = x^1$ if $l \neq 1, \Phi_3 (x^1) = x^1 x^2$.

In order to prove our lemma, it suffices to exhibit three diffeomorphisms $H_i : (Y^p, x_0) \rightarrow (Y^p, x_0)$ ($i = 1, 2, 3$) such that $(H_i)_* = \Phi_i$.

[In the new handle-decomposition for Y^p , induced by H_i , the $[D_1^i]$'s will determine the basis $\Phi_i (x^j)$ of π .]

The construction of H_1, H_2 is an elementary exercise. In order to define H_3 , we start by considering :

$$\bar{Y}^p = (Y^p \cup \partial Y^p \times (0, 1)) / x_0 \times (0, 1),$$

where the notation means that we glue $\partial Y^p \times (0, 1)$ to Y^p , along $\partial Y^p \equiv \partial Y^p \times 0$ and afterwards we contract the fiber $x_0 \times (0, 1)$ to a point. \bar{Y}^p collapses onto Y^p , but on the other hand \bar{Y}^p and Y^p can be identified by a (more or less) canonical diffeomorphism leaving x_0 fixed.

Inside \bar{Y}^p we can slide the handle $D_1^1 \times D_3^1$ (of Y^p) along $D_1^2 \times D_3^2$ (using the positive orientation of D_1^2), without touching x_0 . This changes Y^p into a new subset ${}_1Y^p \subset \bar{Y}^p$, diffeotopic to $Y^p \subset \bar{Y}^p$. ${}_1Y^p$ has a natural handle-decomposition [induced by (2) and by the slide] and since \bar{Y}^p collapses onto ${}_1Y^p$ one gets a handle-decomposition of \bar{Y}^p (hence of Y^p):

$$(3) \quad Y^p = D_i + (\psi_1^i) + \dots + (\psi_1^i)$$

[where $x_0 \in \partial D_i - \cup_i \text{Image}(\psi_1^i)$]. Since

$$\cup_i \text{Image}(\varphi_1^i) \cup_i \text{Image}(\psi_1^i)$$

is just a collection of disjoint disks in $\partial D_i = S_3$, we can find a diffeomorphism :

$$C : D_i + (\varphi_1^i) + \dots \rightarrow D_i + (\psi_1^i) + \dots$$

such that $C(D_i, x_0) = (D_i, x_0)$, $C(D_1^i \times D_3^i) = D_1^i \times D_3^i$, C respects the orientations of the 1-handles. Combining (2), (3) and C , we get our H_3 .

REMARK. — The same argument holds for $p \neq (S_1 \times D_n)$ ($n \geq 2$). On the other hand, using a similar proof, we can show that $\text{Aut}(H_\lambda(p \neq (S_\lambda \times D_n)))$ where $H_* =$ integral homology, $n \geq 2$, is generated by $\pi_0(\text{Diff}(p \neq (S_\lambda \times D_n)))$.

We will also need the following

LEMMA 3. — *Let*

$$f : p \neq (S_1 \times S_2) \rightarrow p \neq (S_1 \times S_2)$$

be an orientation-preserving homeomorphism inducing :

$$f_{i,*} : \pi_i(p \neq (S_1 \times S_2)) \rightarrow \pi_i(p \neq (S_1 \times S_2)).$$

If $f_{1,}$ is the identity then $f_{2,*}$ is also the identity.*

Proof. — f lifts to the universal covering space :

$$\begin{array}{ccc} \tilde{X} & \xrightarrow{\tilde{f}} & \tilde{X} \\ \downarrow & & \downarrow \\ X & \xrightarrow{f} & X \end{array}$$

where $X = p \# (S_1 \times S_2)$. One has a commutative diagramm :

$$\begin{array}{ccc}
 H_2(\tilde{X}) & \xrightarrow{\tilde{f}_*} & H_2(\tilde{X}) \\
 \approx \downarrow & & \approx \downarrow \\
 \pi_2(X) & \xrightarrow{f_{1,*}} & \pi_2(X)
 \end{array} \quad (\text{HUREWICZ})$$

Lemma 3 follows now from :

LEMMA 4. — *Let X_n be a closed orientable topological manifold and $f : X_n \rightarrow X_n$ an orientation preserving homeomorphism, such that $f_{1,*} : \pi_1(X_n) \rightarrow \pi_1(X_n)$ is the identity map. Then*

$$\tilde{f}_* : H_{n-1}(\tilde{X}_n, Z) \rightarrow H_{n-1}(\tilde{X}_n, Z)$$

is also the identity map.

Proof. — Since $H^1(\tilde{X}_n, Z) = 0$ one has a canonical isomorphism $H_c^1(\tilde{X}_n, Z) = H^1(\pi, Z[\pi])$, where $\pi = \pi_1(X_n)$. This isomorphism is functorial, hence the following diagramm is commutative :

$$\begin{array}{ccc}
 H_c^1(\tilde{X}_n, Z) & \xrightarrow{\approx} & H^1(\pi, Z[\pi]) \\
 \downarrow \tilde{f}_* & & \downarrow f_* \\
 H_c^1(\tilde{X}_n, Z) & \xrightarrow{\approx} & H^1(\pi, Z[\pi])
 \end{array}$$

Since $f_* = \text{identity}$, it follows that \tilde{f}_* is the identity too. On the other hand, one has an isomorphism (the Poincaré duality) :

$$H_c^1(\tilde{X}_n, Z) \xrightarrow{D} H_{n-1}(\tilde{X}_n, Z),$$

which is functorial for maps preserving the fundamental class. Now one deduces easily that \tilde{f}_* is the identity map.

REMARK. — Let $b\tilde{X}_n$ be the space of ends of \tilde{X}_n (which is a compact totally discontinuous space). Any homeomorphism $g : X_n \rightarrow X_n$ induces a homeomorphism $\tilde{g} : b\tilde{X}_n \rightarrow b\tilde{X}_n$. If f is like in lemme 4, $\tilde{f} : b\tilde{X}_n \rightarrow b\tilde{X}_n$ is the identity.

Now we can prove our theorem A. We consider the identifications α, β from the beginning of this section. Lemma 2 tells us that we can

always find $H \in \text{Diff}(Y^p)$ such that, if $H_1 = H | \partial Y^p$, the following diagramm is commutative :

$$(4) \quad \begin{array}{ccc} \pi_1(\partial X^p) & \xrightarrow{\alpha_*} & \pi_1(p \# (S_2 \times S_1)) \\ \downarrow h_* & & \uparrow \beta_* \\ \pi_1(\partial Y^p) & \xrightarrow{(H_1)_*} & \pi_1(\partial Y^p) \end{array}$$

Let us assume for the time being that

$$\beta \circ H_1 \circ h \circ \alpha^{-1} : p \# (S_2 \times S_1) \rightarrow p \# (S_2 \times S_1)$$

is orientation-preserving. Consider $x_i \in S_1^i$ [see formula (0)] and the embedded 2-spheres :

$$\Sigma^i = S_2^i \times x_i \subset p \# (S_2 \times S_1).$$

From lemma 3, it follows that Σ^i and $\beta \circ H_1 \circ h \circ \alpha^{-1}(\Sigma^i)$ are homotopic. From [1], section 5, it follows now that there exists an isotopy $H^t \in \text{Diff}(Y^p)$ ($t \in (0, 1)$) such that $H^0 = H$, and

$$\Sigma^i = \beta \circ H_1^t \circ h \circ \alpha^{-1}(\Sigma^i) \subset p \# (S_2 \times S_1).$$

One can also remark that the diffeomorphisms $H_\Sigma(\alpha)$ from [1], section 5.3, extend to elements of $\text{Diff}(p \# (D_3 \times S_1))$. Hence, by [1], 5.4, there exists an $L \in \text{Diff}(Y^p)$ such that : $\beta \circ L_1 \circ H_1^t \circ h \circ \alpha^{-1} = \text{identity}$. Since this means $\beta^{-1} \alpha = ((L \circ H^t) | \partial Y^p) \circ h$, lemma 1 tells us that $X^p \cup_h Y^p = S_i$ (mark that no diffeomorphism of X^p was needed here !).

If $\beta \circ H_1 \circ h \circ \alpha^{-1}$ is not orientation-preserving, we can change (4) into :

$$(5) \quad \begin{array}{ccc} \pi_1(\partial X^p) & \xrightarrow{(F_1)_*} \pi_1(\partial X^p) & \xrightarrow{\alpha_*} \pi_1(p \# (S_2 \times S_1)) \\ \downarrow h_* & & \uparrow \beta_* \\ \pi_1(\partial Y^p) & \xrightarrow{(H_1)_*} & \pi_1(\partial Y^p) \end{array}$$

where $F_1 = F | \partial X^p$, $F \in \text{Diff}(X^p)$ with F orientation-reversing and $(F_1)_*$ = the identity. From here on the proof continues as before.

3. The proof of corollary B

Corollary B follows from theorem A' and the following :

LEMMA 5. — *Let $X^p, (\psi_3^i)$ be as in the statement of corollary B. Then :*

$$\partial(X^p + (\psi_3^1) + \dots + (\psi_3^p)) = S_3 \quad (\text{diffeomorphism}).$$

Proof. — The condition on H_2 implies that $X^p + (\psi_3^i) + \dots$ is contractible. ψ_3^i stands for the attaching map :

$$\psi_3^i : S_2 \times I \hookrightarrow \partial (X^p + (\psi_3^i) + \dots + (\psi_3^{i-1})).$$

For each i , $\psi_3^i \left(S_2 \times \frac{1}{2} \right)$ is a 2-cycle of $\partial (X^p + (\psi_3^i) + \dots + (\psi_3^{i-1}))$ not homologous to 0. [Otherwise (ψ_3^i) would introduce a 3-cycle in $X^p + (\psi_3^i) + \dots + (\psi_3^i)$ which could never be killed by adding 3-cells, only.]

Hence, the $\psi_3^i \left(S_2 \times \frac{1}{2} \right) \hookrightarrow \partial X^p = p \# (S_2 \times S_1)$ are embedded, disjointed, homologically independant. It follows easily that

$$\left(p \# (S_2 \times S_1), \cup \psi_3^i \left(S_2 \times \frac{1}{2} \right) \right)$$

is diffeomorphic to $(p \# (S_2 \times S_1), \cup_i S_2^i \times x^i)$ a. s. o. (Caution : This diffeomorphism does not necessarily extend to X^p .)

4. Final remarks

We will place now corollary B, which is the starting point of our investigation, in its proper context.

If $n \geq 4, n - 2 \geq \lambda \geq 1$, let $C_{n,\lambda}$ denote the class of smooth manifolds of the form

$$X = D_n + (\varphi_\lambda^1) + \dots + (\varphi_\lambda^p) + (\varphi_{\lambda+1}^1) + \dots + (\varphi_{\lambda+1}^p)$$

such that X is contractible.

The h -cobordism theorem of Smale implies that : $X \in C_{n,\lambda} \Rightarrow X = D_n$ provided that : $n \geq 6, n - 3 > \lambda$. On the other hand, $C_{4,1}$ (and in general $C_{n,n-3}$) contains elements with non-simply-connected boundary.

Here are some conjectures for the cases which are not settled :

- C (1) : $X \in C_{4,2} \Rightarrow X = D_4,$
- C (2) : $X \in C_{4,2} \Rightarrow \pi_1 \partial X = 0,$
- C (3) : $X \in C_{5,1} \Rightarrow X = D_5,$
- C (4) : $X \in C_{5,1} \Rightarrow \partial X = S_4.$

$C (2)$ is a very modest version of $C (1)$, while $C (3)$ and $C (4)$ are clearly equivalent. Our corollary B is just the simplest case where we can hope to check $C (1)$. From [2], [3] and very easy arguments, it follows that $C (1) \Rightarrow$ the Poincaré conjecture in dimensions 3 and 4. Also $C (2)$

and the Poincaré conjecture in dimensions 3 and 4 $\Rightarrow C(1), C(3), C(4)$ implies the following weak version of the Poincaré conjecture in dimension 4 : if Σ_4 is a smooth oriented homotopy 4-sphere, then :

$$(6) \quad \Sigma_4 \neq (-\Sigma_4) = S_4 \quad (\text{diffeomorphism}).$$

The Poincaré conjecture in dimension 4 $\Leftrightarrow (6)$ and the smooth 4-dimensional Schoenflies conjecture.
