# LOWER BOUNDS FOR PSEUDO-DIFFERENTIAL OPERATORS 

by N. LERNER ${ }^{(*)}$ and J. NOURRIGAT

## Introduction.

In this paper, we wish to start an investigation on lower bounds for pseudo-differential operators. Our guideline will be one of C. Fefferman and D.H. Phong's conjecture (see $\S 7$ in [6] and [2]) : if $a\left(x, D_{x}\right)$ is a second order operator, its lower bound will be given by some average of its symbol on canonical images of the unit cube in the phase space. Namely, we wish to prove roughly (in some cases) :

$$
a\left(x, D_{x}\right) \geq \inf _{\chi \in \Phi} \iint_{\chi\left(Q_{0}\right)} a(x, \xi) d x d \xi
$$

as an operator, where $Q_{0}$ is the unit cube of $\mathbb{R}^{2 n}, \Phi$ a family of canonical transformations to be specified. The inequality above gives a connection between the geometry of the symbol $a(x, \xi)$ and the spectral properties of its quantization $a\left(x, D_{x}\right)$. Many papers were devoted to these questions. The classical sharp Gårding inequality was first proved by Hörmander [9] :
$a(x, \xi)$ first order $\geq 0$ implies $a\left(x, D_{x}\right)$ semi-bounded from below. We refer to ([11] section 18.1 or [1]) for a proof of this inequality, yielding also the case of systems previously studied by Lax and Nirenberg [12]. Later on, in his paper on the Weyl calculus, Hörmander [10] proved an inequality

[^0]with a "gain" of $6 / 5$ derivatives. Namely, if $a(x, \xi)$ is a symbol of order $6 / 5$ such that
$$
a(x, \xi)+\frac{1}{2} \operatorname{trace}_{+} a \geq 0
$$
then $a\left(x, D_{x}\right)$ is semi-bounded from below. Here trace ${ }_{+} a$ is a positive quantity related to the Hessian of the symbol. On the other hand, C. Fefferman and D.H. Phong proved a two derivative inequality [3] for non-negative symbols :
$a(x, \xi)$ second order $\geq 0$ implies $a\left(x, D_{x}\right)$ semi-bounded from below (see also the proof in [11] section 18.6). On the other hand, C. Fefferman and D.H. Phong [6] discussed the conjecture above for non-negative symbols of order $2-\varepsilon, \varepsilon>0$.

The present paper is concerned with various cases involving symbols which can take large negative values. The first section is devoted to the Schrödinger equation with magnetic potential. In the second section, we discuss the one-dimensional Schrödinger equation, with very little assumptions on the potential. The third section, purely technical, is devoted to miscellaneous properties of the proper class of a symbol. The fourth section contains a proof of the conjecture for pseudo-differential operators in one dimension.

## 1. THE SCHRÖDINGER EQUATION WITH MAGNETIC POTENTIAL

## a. Statement of the result.

We are interested in the following operator

$$
\begin{equation*}
P=\sum_{j=1}^{n}\left(D_{x_{j}}-A_{j}(x)\right)^{2}+V(x), \tag{1.1}
\end{equation*}
$$

where $D_{x_{j}}=\frac{1}{i} \frac{\partial}{\partial x_{j}}$, and $A_{1}, \ldots, A_{n}, V$ are real polynomials of degree $<m$. (Note that $V$ is not assumed to be non-negative). We set-up

$$
\begin{equation*}
p(x, \xi)=\sum_{j=1}^{n}\left(\xi_{j}-A_{j}(x)\right)^{2}+V(x) \tag{1.2}
\end{equation*}
$$

the Weyl symbol of the operator $P$.
We denote by $G_{m}$ the group of canonical transformations of $\mathbf{R}^{2 n}$ of the following type:

$$
\begin{equation*}
(y, \eta) \longrightarrow\left(x_{0}+\lambda y, \lambda^{-1} \eta+\nabla \varphi(y)\right) \tag{1.3}
\end{equation*}
$$

where $x_{0} \in \mathbb{R}^{n}, \lambda>0$ and $\varphi$ is a real polynomial of degree $\leq m$.
Theorem 1.1. - For each integer $m$, there exists $\delta_{m}>0$ such that the following property holds. If $A_{1}, \ldots, A_{n}, V$ are real polynomials of degree $<m$ and if the symbol $p(x, \xi)$ given by (1.2) satisfies

$$
\begin{equation*}
\iint_{\max (|y|,|\eta|) \leq \delta_{m}}(p \circ \chi)(y, \eta) d y d \eta \geq 0, \tag{1.4}
\end{equation*}
$$

for any $\chi$ of $G_{m}$ defined in (1.3). Then the operator $P$, given by (1.1), is non-negative.

In other words, whenever (1.4) is satisfied, we have

$$
\begin{equation*}
\sum_{j=1}^{n}\left\|\left(D_{x_{j}}-A_{j}\right) u\right\|_{L^{2}\left(\mathbf{R}^{n}\right)}^{2}+\int V(x)|u(x)|^{2} d x \geq 0 \tag{1.5}
\end{equation*}
$$

for any $u \in C_{0}^{\infty}\left(\mathbb{R}^{n}\right)$.
Remark 1.2. - The magnetic potential $A=\left(A_{1}, \ldots, A_{n}\right)$ is a oneform $A=\sum_{j=1}^{n} A_{j} d x_{j}$. Its exterior derivative

$$
d A=\sum_{1 \leq k<j \leq n}\left(\frac{\partial A_{j}}{\partial x_{k}}-\frac{\partial A_{k}}{\partial x_{j}}\right) d x_{k} \wedge d x_{j}
$$

will be called curl $A$. Note that the quotient norm of $A$ modulo exact forms is equivalent to the norm of curl $A$ : if $E$ is the space of $I$-forms with polynomial coefficients of degree $<m, F$ the subspace of $\{d \Phi\}$, where $\Phi$ is a polynomial of degree $\leq m, G=d E$, we have $\|A\|_{E / F} \sim\|d A\|_{G}$ where $\left\|\|_{E / F}\right.$ and $\| \|_{G}$ are any norm on the finite dimensional spaces $E / F, G$.

## b. Preliminary lemmas.

The following inequality is proved in a paper by Mohamed and Nourrigat [13]. (See also Helffer-Nourrigat [8] and Nourrigat [14]). It could be seen also as a consequence of [6].

Lemma 1.3 (Local subelliptic estimates with non-negative potential). - For any $m \geq 1$, there exists $C_{m}>0$ and $\varepsilon_{m}>0$ so that, for any polynomials $A_{1}, \ldots, A_{n}$, $V$ of degree $<m$ with $V(x) \geq 0$ on $|x| \leq 1$, we have

$$
\begin{equation*}
\lambda^{\varepsilon}\|u\|^{2} \leq C_{m}\left\{\sum_{j=1}^{n}\left\|\left(D_{j}-A_{j}\right) u\right\|^{2}+(V u, u)\right\} \tag{1.6}
\end{equation*}
$$

for any $u \in C_{0}^{\infty}(|x|<1)$, with

$$
\lambda^{2}=\sup _{|x| \leq 1}\left(|B(x)|^{2}+V(x)\right), \quad B=\operatorname{curl} A
$$

Lemma 1.4. - For any $m \geq 1$, there exists $C_{m}>0$, so that (1.4) implies the following inequality; for any $x_{0} \in \mathbb{R}^{n}$ and any $R>0$ :

$$
\begin{equation*}
0 \leq \frac{\delta_{m}^{4} 2}{R^{2}}+C_{m} \sup _{\left|x-x_{0}\right| \leq R} R^{2}|B(x)|^{2}+\frac{1}{\left|S^{n-1}\right| R^{n}} \int_{\left|x-x_{0}\right| \leq R} V(x) d x \tag{1.7}
\end{equation*}
$$ where $B=\operatorname{curl} A$.

$$
\begin{aligned}
& \text { Proof. - A consequence of }(1.4) \text { is, with } \delta=\delta_{m} \\
& \iint_{\substack{|y| \leq \infty \\
|\eta| \leq \delta}}\left(V\left(x_{0}+\lambda y\right)+\left|\lambda^{-1} \eta+\nabla \varphi(y)-A\left(x_{0}+\lambda y\right)\right|^{2}\right) d y d \eta \geq 0
\end{aligned}
$$

for any $x_{0} \in \mathbb{R}^{n}, \lambda>0, \varphi$ polynomial of degree $\leq m$. Then, we have

$$
\begin{aligned}
\left|B^{n}\right| \lambda^{-n} \delta^{n} \int_{\left|x-x_{0}\right| \leq \lambda \delta} V(x) d x+\iint_{\substack{|y| \leq \delta \\
|\eta| \leq \delta}} \mid \lambda^{-1} \eta+ & \nabla \varphi(y) \\
& -\left.A\left(x_{0}+\lambda y\right)\right|^{2} d y d \eta \geq 0
\end{aligned}
$$

and thus

$$
0 \leq \lambda^{-n} \delta^{n} \int_{\left|x-x_{0}\right| \leq \lambda \delta} V(x) d x+\left|S^{n-1}\right| \delta^{2 n} \sup _{\substack{|,|\leq \infty\\| \eta,| \leq \delta}} \mid \lambda^{-1} \eta+\nabla \varphi(y)
$$

$$
-\left.A\left(x_{0}+\lambda y\right)\right|^{2}
$$

so

$$
\begin{array}{r}
0 \leq(\lambda \delta)^{-n} \delta^{2 n} \int_{\left|x-x_{0}\right| \leq \lambda \delta} V(x) d x+2\left|S^{n-1}\right| \delta^{2 n} \delta^{2} \lambda^{-2}+2\left|S^{n-1}\right| \delta^{2 n} \\
\sup _{|y| \leq \delta}\left\|\nabla \varphi(y)-A\left(x_{0}+\lambda y\right)\right\|^{2}
\end{array}
$$

so, with $R=\lambda \delta$, we have
$0 \leq R^{-n} \int_{\left|x-x_{0}\right| \leq \lambda \delta} V(x) d x+2\left|S^{n-1}\right| \delta^{4} R^{-2}+2\left|S^{n-1}\right| \sup _{|y| \leq \delta} \| \nabla \varphi(y)$

$$
-A\left(x_{0}+\lambda y\right) \|^{2}
$$

Remark 1.2 gives then

$$
\begin{aligned}
0 \leq R^{-n}\left|S^{n-1}\right|^{-1} \int_{\left|x-x_{0}\right| \leq R} V(x) d x+ & 2 \delta^{4} R^{-2} \\
& +2 C_{m} R^{2} \sup _{|y| \leq \delta}\left\|(\operatorname{curl} A)\left(x_{0}+\lambda y\right)\right\|^{2},
\end{aligned}
$$

which completes the proof of (1.7).

## c. Proof of theorem 1.1.

Let $A_{1}, \ldots, A_{n}, V$ be polynomials of degree $<m, B=\operatorname{curl} A$. For a given $x \in \mathbb{R}^{n}$, let's consider the increasing continuous function of $R$

$$
\psi_{x}(R)=\sup _{|y-x| \leq R}\left(R^{2}|B(y)|^{2}+V(y)\right)-\inf _{|y-x| \leq R} V(y)
$$

Assuming that $V$ is not constant, $R \rightarrow \psi_{x}(R)$, is continuous increasing from 0 to $+\infty$ with $R$. Since $R \rightarrow R^{-2}$ is strictly decreasing we can then define, for $\lambda>1$ given, and for $x \in \mathbb{R}^{n}, R(x)$ to be the unique $R \in(0,+\infty)$ so that $\psi_{x}(R)=\lambda^{2} R^{-2}$, i.e.

$$
\begin{equation*}
\sup _{|y-x| \leq R}\left(R^{2}|B(y)|^{2}+V(y)\right)-\inf _{|y-x| \leq R} V(y)=\lambda^{2} R^{-2} . \tag{1.8}
\end{equation*}
$$

Lemma 1.5 (a slowly varying metric on $\mathbb{R}^{n}$ ). - For $x_{1}, x_{2} \in \mathbb{R}^{n}$, $\left|x_{1}-x_{2}\right| \leq \frac{1}{4} R\left(x_{1}\right)$ implies $\frac{1}{2} \leq R\left(x_{1}\right) R\left(x_{2}\right)^{-1} \leq 2$.

Proof. - Assume $\left|x_{2}-x_{1}\right| \leq \frac{1}{2} R_{1}, R_{1}=R\left(x_{1}\right)$. The triangle inequality gives

$$
\begin{aligned}
\psi_{x_{2}}\left(\frac{R_{1}}{2}\right)= & \sup _{\left|y-x_{2}\right| \leq \frac{R_{1}}{2}}\left(\frac{R_{1}^{2}}{4}|B(y)|^{2}+V(y)\right)-\inf _{\left|y-x_{2}\right| \leq \frac{R_{1}}{2}} V(y) \\
& \leq \sup _{\left|y-x_{1}\right| \leq R_{1}}\left(\frac{R_{1}^{2}}{4}|B(y)|^{2}+V(y)\right)-\inf _{\left|y-x_{1}\right| \leq R_{1}} V(y) \\
& \leq \psi_{x_{1}}\left(R_{1}\right)=\lambda^{2} R_{1}^{-2}
\end{aligned}
$$

Consequently, if $\frac{R_{1}}{2}>R_{2}=R\left(x_{2}\right)$, we get $\lambda^{2} R_{1}^{-2} \geq \psi_{x_{2}}\left(\frac{R_{1}}{2}\right) \geq$ $\psi_{x_{2}}\left(R_{2}\right)=\lambda^{2} R_{2}^{-2}$ so $R_{2} \geq R_{1}>2 R_{2}>0$ which is impossible. Thus we have $\frac{R_{1}}{2} \leq R_{2}$.

As in [11] (1.4.5)', $\left|x_{1}-x_{2}\right| \leq \frac{1}{4} R\left(x_{1}\right) \leq \frac{1}{2} R\left(x_{1}\right)$ implies $R\left(x_{1}\right) \leq$ $2 R\left(x_{2}\right)$ and thus $\left|x_{1}-x_{2}\right| \leq \frac{1}{2} R\left(x_{2}\right)$ which gives $R\left(x_{2}\right) \leq 2 R\left(x_{1}\right)$, and the lemma.

The metric $g_{x}(t)=\frac{|t|^{2} 2^{4}}{R(x)^{2}}$ is slowly varying in $\mathbb{R}^{n}$ (cf. definition 1.4.7 in [11]) thus the theorem 1.4.10 in [11] implies the existence of $\left(\varphi_{v}\right)_{v \in \mathbf{N}} \in C_{0}^{\infty}\left(\mathbb{R}^{n}\right),\left(x_{v}\right)_{v \in \mathbf{N}} \in \mathbb{R}^{n}$ so that .
(a) $\operatorname{supp} \varphi_{v} \subset\left\{x,\left|x-x_{v}\right| \leq R_{v}=R\left(x_{v}\right)\right\}=Q_{v}$
(b) $\sum_{v} \varphi_{v}^{2}=1$ identically,
(c) $\sum_{v}\left|\partial_{x}^{\alpha} \varphi_{v}(x)\right|^{2} \leq R(x)^{-2|\alpha|} \gamma_{|\alpha|}$,
where $\gamma_{|\alpha|}$ depends only on $|\alpha|$ and the dimension $n$, but is independent of $\lambda$.

For $v \in \mathbb{N}$, let's define

$$
m_{v}=\inf _{Q_{v}} V(y), \quad V_{v}(t)=R_{v}^{2}\left(V\left(x_{v}+t R_{v}\right)-m_{v}\right) \geq 0
$$

if $|t| \leq 1, A_{v}^{j}(t)=R_{v} A_{j}\left(x_{v}+t R_{v}\right)$, and thus curl $A_{v}=B_{v}=R_{v}^{2} B\left(x_{v}+t R_{v}\right)$, $B=\operatorname{curl} A$.

From (1.8), we have $\lambda^{2}=\sup _{|t| \leq 1}\left(\left|B_{v}(t)\right|^{2}+V_{v}(t)\right)$. Consequently, from (1.6), $\lambda^{\varepsilon}\|u\|^{2} \leq C_{m}\left\{\sum_{j}\left\|\left(D_{j}-A_{v}^{j}\right) u\right\|^{2}+\left(V_{v} u, u\right)\right\}$ for any $u \in C_{0}^{\infty}(|x| \leq 1)$ (the constant $C_{m}$ depends only on the dimension and on the degree of $A$,
$V)$. By translation and dilation we get, for any $u_{v} \in C_{0}^{\infty}\left(Q_{v}\right)$,

$$
\begin{equation*}
\lambda^{\varepsilon} R_{v}^{-2}\left\|u_{v}\right\|^{2} \leq C_{m}\left\{\sum_{j}\left\|\left(D_{j}-A^{j}\right) u_{v}\right\|^{2}+\left(\left(V-m_{v}\right) u_{v}, u_{v}\right)\right\} \tag{1.10}
\end{equation*}
$$

Note that $C_{m}$ does not depend on $\lambda, v$.
The inequality (1.10) implies, for $u \in C_{0}^{\infty}\left(\mathbb{R}^{n}\right)$,

$$
\begin{align*}
\sum_{v} \lambda^{\varepsilon} R_{v}^{-2}\left\|\varphi_{v} u\right\|^{2} \leq C_{m} \sum_{v} \sum_{j=1}^{n} \|\left(D_{j}-\right. & \left.A_{j}\right) \varphi_{v} u \|^{2}  \tag{1.11}\\
& +\sum_{v}\left(\left(V-m_{v}\right) \varphi_{v} u, \varphi_{v} u\right)
\end{align*}
$$

with $\varphi_{v}$ as in (1.9).
Moreover, from (1.9)(c) and the lemma 1.5, we have

$$
\sum_{v}\left\|\nabla \varphi_{v}(x)\right\|^{2} \leq n \gamma_{1} R(x)^{-2} \leq \gamma_{1}^{\prime} \sum_{v} R_{v}^{-2} \varphi_{v}(x)^{2}
$$

where $\gamma_{1}^{\prime}$ depends only on $n$. We then get from (1.11)

$$
\begin{align*}
\lambda^{\varepsilon} \sum_{v} R_{v}^{-2}\left\|\varphi_{v} u\right\|^{2} \leq 2 C_{m}\left\{\sum_{j=1}^{n}\right. & \left.\left\|\left(D_{j}-A_{j}\right) u\right\|^{2}+(V u, u)\right\}  \tag{1.12}\\
& +\sum_{v} C_{m}\left(2 \gamma_{2}^{\prime} R_{v}^{-2}-m_{v}\right)\left\|\varphi_{v} u\right\|^{2}
\end{align*}
$$

Then, we choose $\lambda$ so that $\lambda^{\varepsilon} \geq 4 C_{m} \gamma_{2}^{\prime}$.
The parameter $\lambda$ is fixed in the subsequent computations. We have

$$
\begin{equation*}
\sum_{v}\left(\lambda^{\varepsilon} R_{v}^{-2}+2 C_{m} m_{v}\right)\left\|\varphi_{v} u\right\|^{2} \leq 4 C_{m}\left(\sum_{j=1}^{n}\left\|\left(D_{j}-A_{j}\right) u\right\|^{2}+(V u, u)\right) \tag{1.13}
\end{equation*}
$$

The following lemma implies the theorem 1.1 since $\lambda^{\varepsilon} \geq 1$.
Lemma 1.6 (Choice of $\delta_{m}$ in (1.4) in terms of $\lambda$ ). - For any $\lambda>1$, if $\delta_{m}=\delta$ is chosen small enough, (1.4) implies $2 C_{m} m_{v}+R_{v}^{-2} \geq 0$ for any $v \in \mathbb{N}$.

Proof. - Let $y_{v}$ be a point in $Q_{v}$ at which $V$ is minimum,

$$
m_{v}=V\left(y_{v}\right)=\inf _{y \in Q_{v}} V(y), \quad\left|y_{v}-x_{v}\right| \leq R_{v}
$$

Let's denote by $S_{v}$ the ball with center $y_{v}$ and radius $\beta R_{v}, \beta \in(0,1)$ to be chosen later. We have,

$$
\begin{align*}
& S_{v} \subset Q\left(x_{v}, 2 R_{v}\right)=Q_{v}^{*}  \tag{1.14}\\
& (Q(x, R) \text { is the closed ball with center } x, \text { and radius } R) .
\end{align*}
$$

Moreover, we have, using $V$ is polynomial with degree $\leq m$,

$$
\begin{equation*}
\left|S_{v}\right|^{-1} \int_{S_{v}} V(y) d y \leq m_{v}+C_{m}^{(0)} \beta\left\{\sup _{Q_{v}} V-\inf _{Q_{v}} V\right\}: \tag{1.15}
\end{equation*}
$$

in fact

$$
\begin{aligned}
\left|S_{v}\right|^{-1} \int_{S_{v}} V(y)-m_{v}= & \left|S_{v}\right|^{-1} \int_{S_{v}}\left(V(y)-m_{v}\right) d y \leq \sup _{S_{v}}\left(V(y)-m_{v}\right) \\
& \leq \beta R_{v} \sup _{S_{v}}\|(\nabla V)(y)\| \leq \beta R_{v} \sup _{Q_{v}^{*}}\|\nabla V(y)\| \\
& \leq C_{m} \beta R_{v} \sup _{Q_{v}}\|\nabla V(y)\| \leq C_{m}^{\prime} \beta \sup _{Q_{v}}\left(V(y)-m_{v}\right)
\end{aligned}
$$

which gives (1.15).
Moreover, we have also, using $B$ polynomial with degree $\leq m$,

$$
\begin{equation*}
\sup _{S_{v}}\|B(y)\| \leq \sup _{Q_{v}^{*}}\|B(y)\| \leq C_{m}^{(1)} \sup _{Q_{v}}\|B(y)\| \tag{1.16}
\end{equation*}
$$

So the inequality (1.7) with $x_{0}=y_{v}, R=\beta R_{v}$ gives, together with (1.15), (1.16),
(1.17) $0 \leq \frac{2 \delta^{4}}{\beta^{2} R_{v}^{2}}+C_{m}^{\prime \prime} \beta^{2} R_{v}^{2} \sup _{Q_{v}}\|B(y)\|^{2}+m_{v}+C_{m}^{\prime} \beta\left(\sup _{Q_{v}} V-\inf _{Q_{v}} V\right)$.

But $\lambda^{2} R_{v}^{-2}=\sup _{Q_{v}}\left\{\|B(y)\|^{2} R_{v}^{2}+V(y)-m_{v}\right\}$, thus

$$
\begin{aligned}
\lambda^{2} R_{v}^{-2} \geq\left|Q_{v}\right|^{-1} \int_{Q_{v}}\|B(y)\|^{2} d y R_{v}^{2} & +\left|Q_{v}\right|^{-1} \int_{Q_{v}}\left(V(y)-m_{v}\right) d y \\
& \geq C_{m}^{-1}\left\{\sup _{Q_{v}}\|B(y)\|^{2} R_{v}^{2}+\sup _{Q_{v}} V-\inf _{Q_{v}} V\right\}
\end{aligned}
$$

and consequently $C_{m} \lambda^{2} R_{v}^{-2} \geq \sup _{Q_{v}}\|B(y)\|^{2} R_{v}^{2}+\sup _{Q_{v}} V-\inf _{Q_{v}} V$.
From (1.17), we thus get,

$$
0 \leq \frac{2 \delta^{4}}{\beta^{2} R_{v}^{2}}+\frac{C_{m}^{\prime \prime \prime} \beta^{2} \lambda^{2}}{R_{v}^{2}}+m_{v}+C_{m}^{\prime} \beta \frac{\lambda^{2}}{R_{v}^{2}}
$$

Since $\beta \in(0,1)$, we get

$$
0 \leq \frac{2 \delta^{4}}{\beta^{2} R_{v}^{2}}+C_{m}^{(4)} \beta \frac{\lambda^{2}}{R_{v}^{2}}+m_{v}
$$

Then, we choose $\beta$ so that $C_{m}^{(4)} \beta \lambda^{2} \leq \frac{1}{4 C_{m}}$, then $\delta, \frac{2 \delta^{4}}{\beta^{2}} \leq \frac{1}{4 C_{m}}$ and we get the lemma 1.6.

## 2. SCHRÖDINGER EQUATION IN ONE DIMENSION

## a. Statement of the result.

We study here a one-dimensional Schrödinger equation with very little assumptions on the potential. This result will be useful in the analysis of pseudo-differential operators.

Theorem 2.1. - Let $V \in L_{\mathrm{loc}}^{1}(\mathbb{R})$ such that, for any interval $Q$, with length $|Q|,|Q| \leq 2$,

$$
\begin{equation*}
|Q|^{-1} \int_{Q} V_{+}(t) d t-9|Q|^{-1} \int_{Q} V_{-}(t) d t+|Q|^{-2} \geq 0 \tag{2.1}
\end{equation*}
$$

with $V_{ \pm}=\max ( \pm V, 0)$.
Then

$$
\begin{equation*}
-\frac{d^{2}}{d x^{2}}+V(x) \geq 2^{-4} \mu-1 \tag{2.2}
\end{equation*}
$$

with

$$
\begin{equation*}
\mu=\inf _{Q \text { interval }}\left\{|Q|^{-1} \int_{Q} V(t) d t+|Q|^{-2}\right\} \tag{2.3}
\end{equation*}
$$

Moreover,

$$
\begin{equation*}
\mu \geq \inf _{J \in \mathcal{F}} \iint_{J}\left(|\xi|^{2}+V(x)\right) d x d \xi \tag{2.4}
\end{equation*}
$$

where $\mathcal{F}$ is the following family of "symplectic cubes",

$$
\mathcal{F}=\left\{J_{a, b}\right\}_{a<b \text { real }}, \quad J_{a, b}=\left\{(x, \xi), a \leq x \leq b,|\xi| \leq \frac{1}{2(b-a)}\right\}
$$

We can remark here that a minimal regularity ( $L_{\mathrm{loc}}^{1}$ ) is required for the potential and that, on the other hand, no derivative is lost in the inequality, which appears as a Gårding inequality with gain of 2 full derivatives (see [6]) when $V$ behaves like a symbol. As a matter of fact, if $V$ is a $C^{\infty}$ function such that $\left|V^{(k)}(x)\right| \leq C_{k} M^{2}$, where $M$ is a fixed constant, the nonnegativity condition (2.1) ensures the non-negativity of the second order operator $-\frac{d^{2}}{d x^{2}}+V(x)+1$. Moreover the non-negativity condition in (2.1) is a very weak one and yields potential taking negative values, even singular ones. Note also that the condition is local $(|Q| \leq 2)$ (see also remark 2.2 below).

## b. Proof.

Replacing $V$ by $V+1$, we have, for

$$
\begin{gather*}
Q=Q\left(x_{0}, \delta\right)=\left\{x, x_{0} \leq x \leq x_{0}+\delta\right\} \\
\delta^{-1} \int_{Q} V(x) d x+\delta^{-2} \geq 1, \quad \delta \leq 2 \tag{2.5}
\end{gather*}
$$

as a consequence of (2.1). So we get from (2.5),

$$
\begin{align*}
& \delta \int_{Q} V(x) d x+1 \geq \delta^{2}, \text { and thus } \\
& \delta \int_{Q} V(x) d x>1, \text { if } 4 \geq \delta^{2} \geq 3 \tag{2.6}
\end{align*}
$$

On the other hand, with $V \in L_{\text {loc }}^{1}$,

$$
\begin{equation*}
\lim _{\delta \rightarrow 0} \delta \int_{Q\left(x_{0}, \delta\right)} V(x) d x=0 \tag{2.7}
\end{equation*}
$$

and, for $x_{0}$ fixed, $\delta \rightarrow \delta \int_{Q\left(x_{0}, \delta\right)} V(x) d x$ is a continuous function. So we can pick-up (using (2.6), (2.7) and the continuity) the largest $\delta\left(x_{0}\right)=\delta_{0}$ such that

$$
\begin{equation*}
\delta\left(x_{0}\right) \int_{Q\left(x_{0}, \delta\left(x_{0}\right)\right)=Q_{0}} V(x) d x=1 \tag{2.8}
\end{equation*}
$$

Consequently, we get, with $\mu$ defined in (2.3)

$$
\begin{equation*}
\delta_{0}^{-1} \int_{Q_{0}} V(x) d x=\delta_{0}^{-2} \geq 2^{-1} \mu \tag{2.9}
\end{equation*}
$$

We have now, for $u \in C^{\infty}(\mathbb{R})$ (without assumption on the support of $u$ ),

$$
\begin{align*}
(V u, u)_{Q_{0}}=\int_{Q_{0}} V(x)|u(x)|^{2} d x=\delta_{0}^{-1} & \int_{Q_{0}} V_{+}(x) d x \delta_{0}\left|u\left(x_{+}\right)\right|^{2}  \tag{2.10}\\
& -\delta_{0}^{-1} \int_{Q_{0}} V_{-}(x) d x \delta_{0}\left|u\left(x_{-}\right)\right|^{2}
\end{align*}
$$

for some $x_{+}, x_{-}$in $Q_{0}$.
Thus, from (2.10), we obtain
(2.11) $(V u, u)_{Q_{0}}=\left(\delta_{0}^{-1} \int_{Q_{0}} V(x) d x\right) \delta_{0}\left|u\left(x_{+}\right)\right|^{2}$

$$
+\delta_{0}^{-1} \int_{Q_{0}} V_{-}(x) d x\left\{\delta_{0}\left|u\left(x_{+}\right)\right|^{2}-\delta_{0}\left|u\left(x_{-}\right)\right|^{2}\right\}
$$

From (2.1), (2.9), we get

$$
\begin{equation*}
8 \delta_{0}^{-1} \int_{Q_{0}} V_{-}(x) d x \leq \delta_{0}^{-1} \int_{Q_{0}} V(x) d x+\delta_{0}^{-2} \leq 2 \delta_{0}^{-2} \tag{2.12}
\end{equation*}
$$

So, from (2.11), (2.9) and (2.12) we obtain (using $\left|u\left(x_{+}\right)\right|^{2}-\left|u\left(x_{-}\right)\right|^{2}=$ $\left.\int_{x_{-}}^{x_{+}} 2 \mathbb{R e} u^{\prime}(s) \bar{u}(s) d s\right)$,

$$
\begin{equation*}
(V u, u)_{Q_{0}} \geq \delta_{0}^{-1}\left|u\left(x_{+}\right)\right|^{2}-\delta_{0}^{-1} 2^{-1}\left\|u^{\prime}\right\|_{Q_{0}}\|u\|_{Q_{0}} \tag{2.13}
\end{equation*}
$$

where $\|v\|_{Q_{0}}=\|v\|_{L^{2}\left(Q_{0}\right)}$.
On the other hand, we know (using $\left.u(x)=u\left(x_{+}\right)+\int_{x_{+}}^{x} u^{\prime}(t) d t\right)$

$$
\begin{equation*}
\|u\|_{Q_{0}}^{2} \leq 2 \delta_{0}\left|u\left(x_{+}\right)\right|^{2}+2 \delta_{0}^{2}\left\|u^{\prime}\right\|_{Q_{0}}^{2} \tag{2.14}
\end{equation*}
$$

So, from (2.14), (2.13) we get,

$$
\begin{align*}
& \frac{1}{4} \delta_{0}^{-2}\|u\|_{Q_{0}}^{2} \leq \frac{1}{2} \delta_{0}^{-1}\left|u\left(x_{+}\right)\right|^{2}+\frac{1}{2}\left\|u^{\prime}\right\|_{Q_{0}}^{2} \leq \delta_{0}^{-1}\left|u\left(x_{+}\right)\right|^{2}+\frac{1}{2}\left\|u^{\prime}\right\|_{Q_{0}}^{2} \\
& \quad \leq(V u, u)_{Q_{0}}+\frac{1}{2} \delta_{0}^{-1}\left\|u^{\prime}\right\|_{Q_{0}}\|u\|_{Q_{0}}+\frac{1}{2}\left\|u^{\prime}\right\|_{Q_{0}}^{2}  \tag{2.15}\\
& \quad \leq(V u, u)_{Q_{0}}+\frac{1}{2}\left\|u^{\prime}\right\|_{Q_{0}}^{2}+\frac{1}{2}\left\|u^{\prime}\right\|_{Q_{0}}^{2}+\frac{2}{16 \delta_{0}^{2}}\|u\|_{Q_{0}}^{2}
\end{align*}
$$

Consequently, we have from (2.15), (2.9),

$$
\begin{equation*}
(V u, u)_{Q_{0}}+\left\|u^{\prime}\right\|_{Q_{0}}^{2} \geq \frac{1}{8} \delta_{0}^{-2}\|u\|_{Q_{0}}^{2} \geq \frac{\mu}{16}\|u\|_{Q_{0}}^{2} \tag{2.16}
\end{equation*}
$$

Let's consider now a compact interval $K$ of $\mathbb{R}, x_{0}=\inf K$. Let's define (cf. (2.6), (2.7), (2.8))

$$
\begin{gathered}
\delta_{0}=\delta\left(x_{0}\right)=\sup \left\{\delta, \delta \int_{x_{0}}^{x_{0}+\delta} V(x) d x=1\right\} \\
\delta_{k+1}=\delta\left(x_{0}+\delta_{0}+\cdots+\delta_{k}\right), \quad k \geq 0
\end{gathered}
$$

In order to prove that (2.16) implies (2.2) (for $u \in C_{0}^{\infty}(\mathbb{R})$ ) we need only to prove $x_{0}+\Sigma \delta_{j} \geq \sup K$.

Let's remark that for $\delta>0$ and $[x, x+\delta] \subset K$

$$
\delta \int_{x}^{x+\delta} V(t) d t \leq \delta \int_{x}^{x+\delta}|V(t)| d t \leq \delta \int_{K}|V(t)| d t
$$

So $\delta \int_{x}^{x+\delta} V(t) d t<1$ if $\delta<\delta_{K}=\frac{1}{\int_{K}|V(t)| d t+1}$ and $[x, x+\delta] \subset K$.

So, from the definition of $\delta(x)$, we get $\delta(x)>\delta_{K}$ if $[x, x+\delta(x)] \subset K$, which completes the proof.

Remark 2.2. - Note that, if (2.1) is satisfied for all intervals $Q$, $|Q| \leq 2$ so that $Q \subset[a, b+2]$ we get (2.16) for any $u \in C_{0}^{\infty}(a, b)$ and $Q=\left(x_{k}, x_{k+1}\right), x_{0}=a, x_{k-1}=x_{k}+\delta\left(x_{k}\right)$ as long as $x_{k} \in(a, b)$.

In particular, we get $(V u, u)+\left\|u^{\prime}\right\|^{2} \geq-\|u\|^{2}$ whenever (2.1) is satisfied for intervals $Q,|Q| \leq 2, Q \subset[a, b+2]$ and $u \in C_{0}^{\infty}(a, b)$.

## 3. MISCELLANEOUS PROPERTIES OF THE PROPER CLASS

## a. Preliminary remarks.

The main goal of this section is to prove that a very mild nonnegativity condition for a symbol still ensures that the Calderón-Zygmund procedure used by C. Fefferman and D.H. Phong ([3] - [7]) leads to the same trilogy. More precisely, we intend to show that non-negativity of averages on special "boxes" of volume 1 implies that, in a conformal class of pseudodifferential operators, the symbol is either elliptic positive, or bounded, or non-degenerate i.e. can be written after a canonical transformation

$$
\xi_{1}^{2}+V\left(x_{1}, x^{\prime}, \xi^{\prime}\right)
$$

where $V$ is a pseudo-differential potential.
Let's begin with a simple algebraic lemma.
Lemma 3.1. - Let $\mathcal{A}$ be a real commutative algebra. For any integer $k \geq 1$, there exists an integer $N(k)$ and real numbers $\left(\lambda_{i j}\right) \substack{1 \leq i \leq k \\ 1 \leq j \leq N(k)} \substack{\begin{subarray}{c}{ \\\hline} }} \end{subarray}$ $\left(\mu_{j}\right)_{1 \leq j \leq N(k)}$ with $\max \left(\left|\lambda_{i j},\left|\mu_{j}\right|\right) \leq A(k)\right.$ such that for any $T_{1}, \ldots, \stackrel{\substack{1 \leq \leq \leq N(k)}}{\substack{1}}$

$$
\begin{equation*}
T_{1} \ldots T_{k}=\sum_{1 \leq j \leq N(k)} \mu_{j}\left(\sum_{1 \leq i \leq k} \lambda_{i j} T_{i}\right)^{k} \tag{3.1}
\end{equation*}
$$

Proof. - Induction on $k$. While $4 T_{1} T_{2}=\left(T_{1}+T_{2}\right)^{2}-\left(T_{1}-T_{2}\right)^{2}$ we have to check

$$
\begin{equation*}
T_{1} \ldots T_{k} T_{k+1}=\sum \mu_{j}\left(\sum_{1 \leq i \leq k} \lambda_{i j} T_{i}\right)^{k} T_{k+1} \tag{3.2}
\end{equation*}
$$

It is then enough to write $S^{k} T$ as a sum of $(k+1)$ th power of linear forms in $S, T$ :

$$
\begin{align*}
\sum_{1 \leq j \leq k} \beta_{j}(S+j T)^{k+1}= & \sum_{\substack{0 \leq \ell \leq k+1 \\
1 \leq j \leq k}} C_{k+1}^{\ell} S^{k+1-\ell} \beta_{j} j^{\ell} T^{\ell} \\
= & \left(\sum_{1 \leq j \leq k} \beta_{j}\right) S^{k+1}+(k+1)\left(\sum_{1 \leq j \leq k} j \beta_{j}\right) S^{k} T  \tag{3.3}\\
& +\sum_{2 \leq \ell \leq k} C_{k+1}^{\ell}\left(\sum_{1 \leq j \leq k} j^{\ell} \beta_{j}\right) S^{k+1-\ell} T^{\ell} \\
& +\left(\sum_{1 \leq j \leq k} \beta_{j} j^{k+1}\right) T^{k+1} .
\end{align*}
$$

Let's solve the non singular $k \times k$ linear system with unknowns $\beta_{j}$ :

$$
\begin{gathered}
\sum_{1 \leq j \leq k} j \beta_{j}=\frac{1}{k+1} \\
\sum_{1 \leq j \leq k} j^{\ell} \beta_{j}=0, \quad 2 \leq \ell \leq k
\end{gathered}
$$

Then (3.3) gives

$$
S^{k} T=\sum_{1 \leq j \leq k} \beta_{j}(S+j T)^{k+1}-\left(\sum_{1 \leq j \leq k} \beta_{j} j^{k+1}\right) T^{k+1}-\left(\sum_{j=1}^{k} \beta_{j}\right) S^{k+1}
$$

which gives the result.
Remark 3.2. - An immediate consequence of this lemma is that for any integer $k$, there exists $\alpha(k)>0$, so that for any $k$-multilinear symmetric form $A$ on $\mathbb{R}^{n}$, and any norm $\|\cdot\|$ on $\mathbb{R}^{n}$

$$
\begin{equation*}
1 \leq \sup _{\substack{T_{j} \in \mathbf{R}^{n} \\\left\|T_{j}\right\|=1}}\left|A\left(T_{1}, \ldots, T_{k}\right)\right|\left[\sup _{\substack{T \in \mathbf{R}^{n} \\\|T\|=1}} \mid A(T, \ldots, T)\right]^{-1} \leq \alpha(k) . \tag{3.5}
\end{equation*}
$$

## b. The proper class of a symbol.

Let's now recall the definition of an Hörmander metric on $\mathbb{R}^{2 n}$ (see [11] section 18.5). For each $X \in \mathbb{R}^{2 n}, G_{X}$ is a positive definite quadratic form on $\mathbb{R}^{2 n}$ such that the three following properties are satisfied.
(3.6) There exists $C>0$ such that for any $X, Y, T \in \mathbb{R}^{2 n}, G_{X}(Y-X) \leq$ $C^{-1}$ implies $C^{-1} G_{Y}(T) \leq G_{X}(T) \leq C G_{Y}(T)$.
(3.7) For any $X, T \in \mathbb{R}^{2 n}, G_{X}(T) \leq G_{X}^{\sigma}(T)$ where
$G_{X}^{\sigma}(T)=\inf _{G_{X}(U)=1} \sigma(T, U)^{2}, \sigma$ the symplectic form on $\mathbb{R}^{2 n}$.
There exists $C>0, N$ such that, for any $X, Y, T \in \mathbb{R}^{2 n}$,

$$
\begin{equation*}
G_{X}(T) \leq C G_{Y}(T)\left(1+G_{X}^{\sigma}(X-Y)\right)^{N} \tag{3.8}
\end{equation*}
$$

Let's also define the reciprocal Planck function

$$
\begin{equation*}
\Lambda_{G}(X)=\inf _{T}\left(\frac{G_{X}^{\sigma}(T)}{G_{X}(T)}\right)^{\frac{1}{2}} \quad \text { (note that (3.7) implies } \Lambda \geq 1 \text { ) } \tag{3.9}
\end{equation*}
$$

A function $a \in C^{\infty}\left(\mathbb{R}^{2 n}\right)$ belongs to $S^{m}(G)$ if for any $k$, there exists $C_{k}$ such that

$$
\begin{equation*}
\left|a^{k}(X) T^{k}\right| \leq C_{k} \Lambda_{G}(X)^{m} G_{X}(T)^{k / 2} \tag{3.10}
\end{equation*}
$$

any $X, T \in \mathbb{R}^{2 n}$.
The semi-norms of $a$ are the best constants

$$
\begin{equation*}
\gamma_{k, G}(a)=\sup _{\substack{X . ., \mathbf{R}^{2} \\ G_{X}(T)=1}}\left|a^{k}(X) T^{k}\right| \Lambda_{G}(X)^{-m} \tag{3.11}
\end{equation*}
$$

Note that, from (3.5), we have

$$
\sup _{\substack{x, T_{1} \ldots . T_{k} \in \mathbf{R}^{2 n} \\ G_{X}\left(T_{j}\right)=1}}\left|a^{(k)}(X) T_{1} \ldots T_{k}\right| \Lambda_{G}(X)^{-m} \leq \alpha(k) \gamma_{k, G}(a)
$$

For a given in $S^{2}(G)$ (see 3.10), let's consider

$$
\begin{equation*}
g_{X}=\Lambda_{G}(X) \lambda(X)^{-1} G_{X} \tag{3.12}
\end{equation*}
$$

with

$$
\begin{equation*}
\lambda^{2}(X)=\max _{0 \leq k \leq 3}\left(1,\left\|a^{(k)}(X)\right\|_{G_{X}}^{\frac{4}{4-k}} \Lambda_{G}(X)^{-\frac{2 k}{4-k}}\right) \tag{3.13}
\end{equation*}
$$

where $\left\|a^{(k)}(X)\right\|_{G_{X}}=\sup _{T, G_{X}(T)=1}\left|a^{(k)}(X) T^{k}\right|$.
The next proposition summarizes the properties of a CalderónZygmund decomposition of a symbol (see [3], [6]).

Proposition 3.3. - (a) The metric $g$ defined by (3.12) is an Hörmander metric, i.e. satisfies (3.6), (3.7), (3.8). The constants in (3.6) for $g$ depend only on the constants in (3.6) for $G$ and on $\left(\gamma_{k G}(a)\right)_{0 \leq k \leq 4}$.
(b) We have $\lambda_{g}(X)=\lambda(X)$, according to (3.12) and (3.9).
(c) The symbol $a \in S^{2}(g)$ and

$$
\gamma_{k g}(a) \leq 1 \text { if } k \leq 3
$$

$$
\gamma_{k g}(a) \leq \gamma_{k G}(a) \max _{0 \leq \ell \leq 3}\left(1,\left(\gamma_{\ell G}(a)\right)^{\frac{k-4}{4-\ell}}\right) \text { if } k \geq 4
$$

(d) We have $\lambda(X) \leq \Lambda(X) \max _{0 \leq k \leq 3}\left(1,\left(\gamma_{k G}(a)\right)^{\frac{2}{4-k}}\right)$.

Proof. - The points (b) and (a) (3.7) are obvious from the definitions. Let's prove (c) : if $k \leq 3$, from (3.13) we get

$$
\begin{align*}
&\left\|a^{(k)}(X)\right\|_{g_{X}}=\left\|a^{(k)}(X)\right\|_{G_{X}} \Lambda(X)^{-\frac{k}{2}} \lambda(X)^{\frac{k}{2}}  \tag{3.14}\\
& \leq \Lambda^{-\frac{k}{2}} \lambda^{\frac{k}{2}}\left(\lambda^{2} \Lambda^{\frac{2 k}{4-k}}\right)^{\frac{4-k}{4}}=\lambda(X)^{2}
\end{align*}
$$

Moreover, if $\ell \geq 4$, we have

$$
\begin{align*}
&\left\|a^{(\ell)}(X)\right\|_{g_{X}}=\left\|a^{(\ell)}(X)\right\|_{G_{X}} \Lambda(X)^{-\frac{\ell}{2}} \lambda(X)^{\frac{\ell}{2}}  \tag{3.15}\\
& \leq \Lambda^{2-\frac{\ell}{2}} \lambda^{\frac{\ell}{2}-2} \lambda^{2} \gamma_{\ell G}(a)=\lambda^{2} \gamma_{\ell G}(a)\left(\frac{\lambda^{2}}{\Lambda^{2}}\right)^{\frac{\ell-4}{4}}
\end{align*}
$$

But, from (3.13), we have

$$
\begin{equation*}
\Lambda(X)^{-2} \lambda(X)^{2} \leq \max _{0 \leq k \leq 3}\left(1, \gamma_{k G}(a)^{\frac{4}{4-k}}\right) \max _{0 \leq k \leq 3}\left(\Lambda(X)^{\frac{8-2 k}{4-k}-2}, 1\right) \tag{3.16}
\end{equation*}
$$

so we obtain, from (3.15), (3.16) and $\ell \geq 4$,

$$
\begin{equation*}
\left\|a^{(\ell)}(X)\right\|_{g_{X}} \leq \lambda(X)^{2} \gamma_{\ell G}(a) \max _{0 \leq k \leq 3}\left(1, \gamma_{k G}(a)^{\frac{\ell-4}{4-k}}\right) \tag{3.17}
\end{equation*}
$$

So (3.14) and (3.17) gives (c) in proposition 3.3.
Note also that (3.16) gives

$$
\begin{equation*}
\frac{\lambda(X)}{\Lambda(X)} \leq \max _{0 \leq k \leq 3}\left(1, \gamma_{k G}(a)^{\frac{2}{4-k}}\right) \tag{3.18}
\end{equation*}
$$

that is (d) in proposition 3.3. Then it suffices to prove (a) (3.6) since the proposition 18.5.6 in Hörmander's book [11] can be applied ( $g$ is conformal to $G$ ), to get (a) (3.8). As pointed out in [11] (1.4.5)', it is enough to prove the existence of $\delta, C$ such that

$$
\begin{equation*}
g_{X}(Y-X) \leq \delta \text { implies } g_{Y} \leq C g_{X} \tag{3.19}
\end{equation*}
$$

Let us first remark that

$$
\begin{equation*}
\lambda^{2}(X)=\max _{0 \leq k \leq 3}\left(1,\left\|a^{(k)}(X)\right\|_{g_{X}}\right) \tag{3.20}
\end{equation*}
$$

As a matter of fact, we get

$$
\begin{equation*}
\max _{0 \leq k \leq 3}\left(1,\left\|a^{(k)}(X)\right\|_{g_{X}}\right) \leq \lambda^{2}(X) \tag{3.21}
\end{equation*}
$$

from the proposition 3.3 (c) (already proved!) and $\lambda \geq 1$. Conversely, if $\max _{0 \leq k \leq 3}\left(\left\|a^{(k)}(X)\right\|_{g_{X}}^{\frac{4}{4-k}} \Lambda(X)^{-\frac{2 k}{4-k}}\right)>1$, then, from (3.13), we obtain

$$
\lambda^{2}(X)=\left\|a^{\left(k_{0}\right)}(X)\right\|_{g_{X}}^{\frac{4}{4-k_{0}}} \Lambda(X)^{-\frac{2 k_{0}}{4-k_{0}}}
$$

for some $k_{0}, 0 \leq k_{0} \leq 3$ ( $X$ is fixed). Thus, (3.12) gives

$$
\lambda^{2}(X)=\left\|a^{\left(k_{0}\right)}(X)\right\|_{g_{X}}^{\frac{4}{4-k_{0}}} \Lambda(X)^{\frac{k_{0}}{2}\left(\frac{4}{4-k_{0}}\right)} \lambda(X)^{-\frac{k_{0}}{2} \frac{4}{4-k_{0}}} \Lambda(X)^{-\frac{2 k_{0}}{\left(4-k_{0}\right)}}, \text { i.e. }
$$

$$
\begin{equation*}
\lambda^{2}(X)=\left\|a^{\left(k_{0}\right)}(X)\right\|_{g_{X}} \tag{3.22}
\end{equation*}
$$

Now, if $\max _{0 \leq k \leq 3}\left(\left\|a^{(k)}(X)\right\|_{G_{X}}^{\frac{4}{4-k}} \Lambda(X)^{-\frac{2 k}{4-k}}\right) \leq 1$, we have, from (3.13),

$$
\begin{equation*}
\lambda^{2}(X)=1 \tag{3.23}
\end{equation*}
$$

So we get (3.20) from (3.21), (3.22), (3.23). Let us assume that $G$ is slowly varying (i.e. satisfies (3.6)) with a constant $C_{0}$, and take $\delta$ such that

$$
\begin{equation*}
\delta C_{0} \max _{0 \leq k \leq 3}\left(1, \gamma_{k G}(a)^{\frac{2}{4-k}}\right) \leq 1 \tag{3.24}
\end{equation*}
$$

If $g_{X}(Y-X) \leq \delta$, then $G_{X}(Y-X) \leq \frac{\lambda(X)}{\Lambda(X)} \delta$, and thus, using proposition 3.3 (d) (already proved) we obtain,

$$
G_{X}(Y-X) \leq \max _{0 \leq k \leq 3}\left(1, \gamma_{k G}(a)^{\frac{2}{4-k}}\right) \delta \leq C_{0}^{-1} \quad \text { by }(3.24)
$$

Consequently $C_{0}^{-1} G_{X} \leq G_{Y} \leq C_{0} G_{X}$. We need thus only to estimate from above the ratio $\frac{\lambda(X)}{\lambda(Y)}$ to get the conclusion of (3.19).

From Taylor's formula, $0 \leq k \leq 3$, we have

$$
\begin{align*}
\left\|a^{(k)}(X)\right\|_{g_{X}} \leq & \sum_{k \leq \ell \leq 3} \frac{1}{(\ell-k)!}\left\|a^{(\ell)}(Y)\right\|_{g_{X}} g_{X}(Y-X)^{\frac{\ell-k}{2}} \\
& +\frac{1}{(4-k)!} \sup _{Z \in[X, Y]}\left\|a^{(4)}(Z)\right\|_{g_{X}} g_{X}(Y-X)^{\frac{4-k}{2}}  \tag{3.25}\\
\leq & \sum_{k \leq \ell \leq 3}\left\|a^{(\ell)}(Y)\right\|_{g_{Y}}\left(\frac{\lambda(X)}{\lambda(Y)}\right)^{\frac{\ell}{2}} C_{1} \delta^{\frac{\ell-k}{2}}+\delta^{\frac{4-k}{2}} \gamma_{4 G}(a) C_{1} \lambda(X)^{2},
\end{align*}
$$

where $C_{1}$ depends only on $C_{0}$, since $\left\|a^{(4)}(Z)\right\|_{g_{X}}=\left\|a^{(4)}(Z)\right\|_{\frac{\Lambda(X)}{\lambda(X)} G_{X}}$, and thus

$$
\left\|a^{(4)}(Z)\right\|_{g_{X}}=\left\|a^{(4)}(Z)\right\|_{G_{X}} \frac{\lambda(X)^{2}}{\Lambda(X)^{2}} \leq \gamma_{4, G}(a) C_{1} \Lambda(X)^{2} \frac{\lambda(X)^{2}}{\Lambda(X)^{2}}
$$

we have in fact $Z=(1-\theta) X+\theta Y, \theta \in[0,1]$ and consequently $G_{X}(Z-X) \leq$ $G_{X}(Y-X) \leq C_{0}^{-1}$, so that $C_{0}^{-1} G_{X} \leq G_{Z} \leq C_{0} G_{X}$, and $\Lambda(X)$ is equivalent to $\Lambda(Z)$.

Now, using (3.20), we may assume $\lambda^{2}(X)=\left\|a^{(k)}(X)\right\|_{g_{X}}$, for some $k$, $0 \leq k \leq 3$ (otherwise $\lambda(X)=1$ and since $\lambda(Y) \geq 1$ we get $\frac{\lambda(X)}{\lambda(Y)} \leq 1$ ).

We obtain, from (3.20) and (3.25),

$$
\begin{equation*}
\lambda^{2}(X) \leq \lambda(Y)^{2} \sum_{k \leq \ell \leq 3} C_{1}\left(\frac{\lambda(X)}{\lambda(Y)}\right)^{\frac{\ell}{2}} \delta^{\frac{\ell-k}{2}}+\delta^{\frac{4-k}{2}} \gamma_{4 G}(a) C_{1} \lambda(X)^{2} \tag{3.26}
\end{equation*}
$$

Consequently, if $\delta$ satisfies (3.24) and

$$
\begin{equation*}
\sup _{0 \leq k \leq 3} \delta^{\frac{4-k}{2}} \gamma_{4 G}(a) C_{1} \leq \frac{1}{2} \tag{3.27}
\end{equation*}
$$

we get

$$
\left(\frac{\lambda(X)}{\lambda(Y)}\right)^{2} \leq 2 C_{1} \sum_{k \leq \ell \leq 3}\left(\frac{\lambda(X)}{\lambda(Y)}\right)^{\frac{\ell}{2}} \delta^{\frac{\ell-k}{2}}
$$

so the term $\frac{\lambda(X)}{\lambda(Y)}$ must be bounded from above by a constant depending on $\delta$ and $C_{1}$, that is on $C_{0}$ (in (3.6) for $G$ ) and $\left(\gamma_{k G}(a)\right)_{0 \leq k \leq 4}$. The proof of proposition 3.3 is complete.

## c. Fefferman-Phong's classification.

The rest of section 4 is devoted to the proof of the following proposition, ensuring that Fefferman-Phong's classification is still valid under a positivity assumption on averages.

Proposition 3.4. - Let $G$ be an Hörmander metric on $\mathbb{R}^{2 n}$ (i.e. satisfying (3.6), (3.7) and (3.8)), a a symbol in $S^{2}(G)$ (see (3.10)) and $g$ the proper metric of a defined by (3.12) and proposition 3.3.
(3.28) Let us assume that the averages of $a$ on $G$-balls of symplectic volume 1 are non-negative.

Then, there exists positive constants $C, \rho$ depending only on a finite number of semi-norms of $a$ such that the proper metric of $a$ is made with three types of "boxes" : for any $X_{0}$ in $\mathbb{R}^{2 n}$ and any $X$ in the $g_{X_{0}}$ ball of radius $\rho$ and center $X_{0}$,
(1) Either $\lambda(X) \leq C$,
(2) or $a(X) \lambda(X)^{-2} \geq C^{-1}$
(3) or $a(X)=e_{0}(X)\left(X_{1}-\alpha\left(X^{\prime}\right)\right)^{2}+b\left(X^{\prime}\right)$.

Here $X_{1}, X^{\prime}$ is a set of linear symplectic coordinates, and the functions $\lambda\left(X_{0}\right)^{-1} e_{0}, \lambda\left(X_{0}\right)^{-2} b, \lambda\left(X_{0}\right)^{-1 / 2} \alpha$ satisfy the estimates of $S^{0}(g)$ with seminorms controlled by those of $a$ and $\lambda^{-1} e_{0} \geq C^{-1}>0$.

Let's give a
Definition 3.5. - Given $\delta, \varepsilon$ positive numbers, $a \in \mathcal{A}(\delta, \varepsilon)$ means that $a$ is a $C^{\infty}$ function on $|X| \leq 1$ so that
(i) $\left|a^{(k)}(X)\right| \leq 1,0 \leq k \leq 4$
(ii) $\max _{0 \leq k \leq 3}\left|a^{(k)}(0)\right| \geq \delta$
(iii) The averages of $a$ on balls of radius $\varepsilon$ (included in the unit ball) are non-negative.

The proposition 3.4 is a consequence of the following lemma by rescaling, using (3.20).

Lemma 3.6. - Let $\delta$ be a positive number. There exist $r(\delta), \varepsilon(\delta)$ and $\omega(\delta)$ positive so that, if $a \in \mathcal{A}(\delta, \varepsilon)$ with $\varepsilon \leq \varepsilon(\delta)$, then, on $|X| \leq r(\delta)$,
(1) Either $a(X) \geq \omega(\delta)$
(2) Or, for some choice of euclidean coordinates,

$$
a(X)=a\left(\alpha\left(X^{\prime}\right), X^{\prime}\right)+e_{0}(X)\left(X_{1}-\alpha\left(X^{\prime}\right)\right)^{2}
$$

with $e_{0}(X) \geq \omega(\delta)$ and, for all $k$,

$$
\max _{|X| \leq r(\delta)}\left(\left|e_{0}^{(k)}(X)+\left|\alpha^{(k)}(X)\right|\right) \leq C(k) F\left(\max _{\substack{|x| \leq r(\delta) \\ \ell \leq k+2}}\left|a^{(\ell)}(X)\right|\right) .\right.
$$

Proof. - Let $\left.\left.\mu_{0} \in\right] 0,1\right]$.
(1) Assume $|a(0)| \geq \mu_{0}>0$.

If $a(0) \leq-\mu_{0}, a(X) \leq-\mu_{0} / 2$ on $|X| \leq \mu_{0} / 2$, which contradicts (iii) if $\varepsilon \leq \mu_{0} / 2, \mu_{0} \leq 1$.

Consequently, we have in that case $|a(X)| \geq \mu_{0} / 2$ on $|X| \leq \mu_{0} / 2$.
(2) Assume $|a(0)|<\mu_{0},\left|a^{\prime}(0)\right| \geq \mu_{1}>0$.

Then, for some choice of euclidean coordinates,

$$
\frac{\partial a}{\partial X_{1}}\left(X_{1}, X^{\prime}\right) \geq \frac{\mu_{1}}{2} \quad \text { on } \quad|X| \leq \frac{\mu_{1}}{2} \leq 1
$$

and thus

$$
a\left(X_{1}, 0\right)=a(0,0)+e_{0}\left(X_{1}\right) X_{1}, \quad e_{0}\left(X_{1}\right) \geq \mu_{1} / 2, \text { if }\left|X_{1}\right| \leq \mu_{1} / 2
$$

Thus

$$
a\left(X_{1}, 0\right) \leq \mu_{0}-\frac{\mu_{1}^{2}}{2^{3}} \leq-\frac{\mu_{1}^{2}}{2^{4}}, \text { if }-\frac{\mu_{1}}{2} \leq X_{1} \leq-\frac{\mu_{1}}{2^{2}} \text { and } \mu_{0} \leq \frac{\mu_{1}^{2}}{2^{4}}
$$

Consequently
$a\left(X_{1}, X^{\prime}\right) \leq a\left(X_{1}, 0\right)+\left|X^{\prime}\right| \leq-\frac{\mu_{1}^{2}}{2^{5}}$, if $\left|X^{\prime}\right| \leq \frac{\mu_{1}^{2}}{2^{5}} \leq 1,-\frac{\mu_{1}}{2} \leq X_{1} \leq-\frac{\mu_{1}}{4}$, which contradicts (iii) if $\varepsilon \leq \frac{\mu_{1}^{2}}{32}, \frac{\mu_{1}}{4} \leq 1$.
(3) Assume $|a(0)|<\mu_{0},\left|a^{\prime}(0)\right|<\mu_{1},\left|a^{\prime \prime}(0)\right| \geq \mu_{2}>0$. Then, for some choice of euclidean coordinates (see lemma 3.1),

$$
\left|\frac{\partial^{2} a}{\partial X_{1}^{2}}(X)\right| \geq \frac{\mu_{2}}{2} \quad \text { on } \quad|X| \leq \frac{\mu_{2}}{2} \leq 1
$$

If $\left|\frac{\partial^{2} a}{\partial X_{1}^{2}}(0)\right| \leq-\mu_{2}, \frac{\partial^{2} a}{\partial X_{1}^{2}}(X) \leq-\frac{\mu_{2}}{2}$ on $|X| \leq \frac{\mu_{2}}{2} \leq 1$. Thus

$$
a\left(X_{1}, 0\right) \leq \mu_{0}+\mu_{1}\left|X_{1}\right|-\frac{\mu_{2}}{4} X_{1}^{2} \text { on } \frac{\mu_{2}}{4} \leq X_{1} \leq \frac{\mu_{2}}{2} \leq 1
$$

Consequently, there, we have

$$
a\left(X_{1}, 0\right) \leq \mu_{0}+\frac{\mu_{1} \mu_{2}}{2}-\frac{\mu_{2}^{3}}{2^{6}} \leq-\frac{\mu_{2}^{3}}{2^{7}} \text { if } \mu_{0}+\frac{\mu_{1} \mu_{2}}{2} \leq \frac{\mu_{2}^{3}}{2^{7}}
$$

e.g. if

$$
\mu_{0} \leq \frac{\mu_{2}^{3}}{2^{8}}, \quad \frac{\mu_{1}}{2} \leq \frac{\mu_{2}^{2}}{2^{8}}
$$

Then, we get $a\left(X_{1}, X^{\prime}\right) \leq-\frac{\mu_{2}^{3}}{2^{8}}$ if $\left|X^{\prime}\right| \leq \frac{\mu_{2}^{3}}{2^{8}}$, which contradicts (iii) if

$$
\varepsilon<\frac{\mu_{2}^{3}}{2^{8}}, \quad \mu_{2} \leq 1
$$

(4) From case (3) above, if $|a(0)| \leq \mu_{0},\left|a^{\prime}(0)\right|<\mu_{1},\left|a^{\prime \prime}(0)\right| \geq \mu_{2}$, we must have $\frac{\partial^{2} a}{\partial X_{1}^{2}}\left(X_{1}, X^{\prime}\right) \geq \frac{\mu_{2}}{2}$ on $|X| \leq \frac{\mu_{2}}{2}$.

Moreover, $\frac{\partial a}{\partial X_{1}}\left(X_{1}, X^{\prime}\right)=\frac{\partial a}{\partial X_{1}}\left(0, X^{\prime}\right)+e_{0}(X) X_{1}$, with $e_{0}(X) \geq \frac{\mu_{2}}{2}$, if $|X| \leq \frac{\mu_{2}}{2}$. Thus

$$
\left|\frac{\partial a}{\partial X_{1}}\left(0, X^{\prime}\right)\right| \leq \mu_{1}+\left|X^{\prime}\right| \leq 2 \mu_{1}, \quad \text { if } \quad\left|X^{\prime}\right| \leq \mu_{1}
$$

Thus

$$
\frac{\partial a}{\partial X_{1}}\left(\frac{\mu_{2}}{2}, X^{\prime}\right) \geq-2 \mu_{1}+\frac{\mu_{2}^{2}}{4}>0, \text { if } \frac{\mu_{2}^{2}}{4}>2 \mu_{1}
$$

Also

$$
\frac{\partial a}{\partial X_{1}}\left(-\frac{\mu_{2}}{2}, X^{\prime}\right) \leq 2 \mu_{1}-\frac{\mu_{2}^{2}}{4}<0
$$

So for any $X^{\prime},\left|X^{\prime}\right| \leq \inf \left(\mu_{1}, \frac{\mu_{2}}{2}\right) \leq 1$, there exists $a\left(X^{\prime}\right) \in\left(-\frac{\mu_{2}}{2}, \frac{\mu_{2}}{2}\right)$, $\frac{\partial a}{\partial X_{1}}\left(\alpha\left(X^{\prime}\right), X^{\prime}\right)=0$.

By the implicit function theorem, $\alpha$ is a smooth function and its $K^{t h}$ derivatives are controlled by fixed polynomials of the $(k+1)^{t h}$ derivatives of $a$ and $\left(\frac{\partial^{2} a}{\partial X_{1}^{2}}\right)^{-1}$. We get then

$$
a\left(X_{1}, X^{\prime}\right)=a\left(\alpha\left(X^{\prime}\right), X^{\prime}\right)+e(X)\left(X_{1}-\alpha\left(X^{\prime}\right)\right)^{2}, \quad e(X) \geq \frac{\mu_{2}}{2}
$$

on $|X| \leq \inf \left(\mu_{1}, \frac{\mu_{2}}{2}\right) \leq 1$.
(5) If $|a(0)|<\mu_{0},\left|a^{\prime}(0)\right|<\mu_{1},\left|a^{\prime \prime}(0)\right|<\mu_{2},\left|a^{\prime \prime \prime}(0)\right| \geq \mu_{3}$.

We get, from lemma $3.1, \frac{\partial^{3} a}{\partial X_{1}^{3}}(X) \geq \frac{\mu_{3}}{2}$ if $|X| \leq \frac{\mu_{3}}{2} \leq 1$.
Then on $-\frac{\mu_{3}}{2} \leq X_{1} \leq-\frac{\mu_{3}}{4}$

$$
a\left(X_{1}, 0\right) \leq \mu_{0}+\mu_{1} \frac{\mu_{3}}{2}+\frac{1}{2} \mu_{2}\left(\frac{\mu_{3}}{2}\right)^{2}-\frac{1}{6} \frac{\mu_{3}}{2}\left(\frac{\mu_{3}}{4}\right)^{3} \leq-\frac{1}{2} \frac{1}{6} \frac{\mu_{3}^{4}}{2^{7}}
$$

if $\mu_{0}<\frac{1}{3} \frac{1}{2} \frac{1}{6} \frac{\mu_{3}^{4}}{2^{7}}$, and $\mu_{1}<\frac{1}{3} \frac{1}{6} \frac{\mu_{3}^{3}}{2^{7}}$, and $\mu_{2}<\frac{1}{3} \frac{1}{6} 2^{2} \frac{\mu_{3}^{2}}{2^{7}}$.
Thus, we have,

$$
a\left(X_{1}, X^{\prime}\right) \leq-\frac{1}{4} \frac{1}{6} \frac{\mu_{3}^{4}}{2^{7}}, \text { if }\left|X^{\prime}\right| \leq \frac{1}{4} \frac{1}{6} \frac{\mu_{3}^{4}}{2^{7}}, \quad-\frac{\mu_{3}}{2} \leq X_{1} \leq-\frac{\mu_{3}}{4}
$$

which contradicts (iii) if $\varepsilon \leq \min \left(\frac{1}{4} \frac{1}{6} \frac{\mu_{3}^{4}}{2^{7}}, \frac{\mu_{3}}{4}\right)$.
(6) Assume $|a(0)|<\mu_{0},\left|a^{\prime}(0)\right|<\mu_{1},\left|a^{\prime \prime}(0)\right|<\mu_{2},\left|a^{\prime \prime \prime}(0)\right| \leq \mu_{3}$. This contradicts (ii) if $\max \left(\mu_{0}, \mu_{1}, \mu_{2}, \mu_{3}\right)<\delta$.

Eventually, we have to perform the following successive (and compatible!) choices with $\delta>0$ given.

First choose

$$
\mu_{3}, \quad 0<\mu_{3}<\min \left(\frac{\delta}{2}, 1\right)
$$

then

$$
\mu_{2}, \quad 0<\mu_{2} \leq \min \left(\frac{1}{3} \frac{1}{6} \frac{\mu_{3}^{2}}{2^{6}}, \frac{\delta}{2}, 1\right)
$$

then

$$
\mu_{1}, \quad 0<\mu_{1} \leq \min \left(\frac{1}{3} \frac{1}{6} \frac{\mu_{3}^{3}}{2^{7}}, \frac{\delta}{2}, \frac{\mu_{2}^{2}}{2^{7}}, 1\right)
$$

then

$$
\mu_{0}, \quad 0<\mu_{0} \leq \min \left(\frac{1}{3} \frac{1}{2} \frac{1}{6} \frac{\mu_{3}^{4}}{2^{7}}, \frac{\delta}{2}, \frac{\mu_{2}^{3}}{2^{8}}, 1, \frac{\mu_{1}^{2}}{16}\right) .
$$

Then $\varepsilon(\delta)$ can be taken as

$$
\varepsilon(\delta)=\min \left(\frac{1}{4} \frac{1}{6} \frac{\mu_{3}^{4}}{2^{7}}, \frac{\mu_{2}^{3}}{2^{8}}, \frac{\mu_{1}^{2}}{2^{5}}, \frac{\mu_{0}}{2}\right)
$$

and

$$
r(\delta)=\min \left(\frac{\mu_{0}}{2}, \mu_{1}, \frac{\mu_{2}}{2}\right), \omega(\delta)=\mu_{2} .
$$

The lemma 3.6 is proved.
End of the proof of proposition 3.4.
Let's now consider $X_{0} \in \mathbb{R}^{2 n}$. We can assume (see lemma 18.6.4 in[11]) that

$$
\begin{equation*}
g_{X_{0}}=g=\sum_{j=1}^{n} \lambda_{j}^{-1}\left(d x_{i}^{2}+d \xi_{j}^{2}\right), \text { with } \inf \lambda_{j}=\lambda=\lambda\left(X_{0}\right) . \tag{3.29}
\end{equation*}
$$

We are going to apply lemma 3.6 to

$$
A\left(t_{1}, \ldots, t_{n}, \tau_{1}, \ldots, \tau_{n}\right)=\lambda^{-2} a\left(X_{0}+\sum_{j=1}^{n} t_{j} \lambda_{j}^{1 / 2} e_{j}+\tau_{j} \lambda_{j}^{1 / 2} \varepsilon_{j}\right)
$$

where ( $e_{j}, \varepsilon_{j}$ ) is the "canonical" basis of $\mathbb{R}^{2 n}$ in the coordinates corresponding to the diagonalization of $g$ in (3.29). The case (1) and (2) in proposition 3.4 are easily obtained from (1) of lemma 3.6 or by assuming $\lambda \leq C$. The case (3) is obtained as follows : we get, assuming $X_{0}=0$,

$$
\left(\eta_{1}-\alpha\left(y, \eta^{\prime}\right)\right)^{2} e_{0}(y, \eta) \lambda^{2}+b\left(y, \eta^{\prime}\right) \lambda^{2}=a\left(\sum_{j=1}^{n} t_{j} \lambda_{j}^{1 / 2} e_{j}+\tau_{j} \lambda_{j}^{1 / 2} \varepsilon_{j}\right),
$$

where $\binom{\eta}{y}=\Omega\binom{\tau}{t}$, where the $2 n \times 2 n$ matrix $\Omega$ is orthogonal.
So, we obtain, setting-up $x_{j}=t_{j} \lambda_{j}^{1 / 2}, \xi_{j}=t_{j} \lambda_{j}^{1 / 2}$,
$a(x, \xi)=\lambda\left(\lambda^{1 / 2} \eta_{1}\left(\frac{x_{j}}{\lambda_{j}^{1 / 2}}, \frac{\xi_{j}}{\lambda_{j}^{1 / 2}}\right)-\lambda^{1 / 2} \alpha\left(y\left(\frac{x_{j}}{\lambda_{j}^{1 / 2}}, \frac{\xi_{j}}{\lambda_{j}^{1 / 2}}\right), \eta^{\prime}\left(\frac{x_{j}}{\lambda_{j}^{1 / 2}}, \frac{\xi_{j}}{\lambda_{j}^{1 / 2}}\right)\right)\right)^{2}$
$e_{0}\left(y\left(\frac{x_{j}}{\lambda_{j}^{1 / 2}}, \frac{\xi_{j}}{\lambda_{j}^{1 / 2}}\right), \eta\left(\frac{x_{j}}{\lambda_{j}^{1 / 2}}, \frac{\xi_{j}}{\lambda_{j}^{1 / 2}}\right)\right)+\lambda^{2} b\left(y\left(\frac{x_{j}}{\lambda_{j}^{1 / 2}}, \frac{\xi_{j}}{\lambda_{j}^{1 / 2}}\right), \eta^{\prime}\left(\frac{x_{j}}{\lambda_{j}^{1 / 2}}, \frac{\xi_{j}}{\lambda_{j}^{1 / 2}}\right)\right)$.
Through a linear symplectic change of coordinates we have, on the $g$-ball with center 0 and radius $r(\delta)$

$$
\begin{equation*}
a(x, \xi)=\lambda\left(\eta_{1}-\beta\left(y, \eta^{\prime}\right)\right)^{2} e_{0}(y, \eta)+b_{0}\left(y, \eta^{\prime}\right) \lambda^{2} \tag{3.30}
\end{equation*}
$$

that is the result of proposition 3.4.

## d. Sharp Egorov principle.

The problem can be microlocalized. If $\left\{\chi_{v}(x, \xi)^{2}\right\}_{v}$ is a partition of unity related to the metric $g$ (see [11] section 18.5)

$$
a^{w}=\sum_{v}\left(\chi_{v}^{2} a\right)^{w}=\sum_{v}\left(\chi_{v} \sharp a \sharp \chi_{v}\right)^{w}+r^{w}, \quad \text { where } r^{w} \text { is } L^{2} \text { bounded. }
$$

Moreover, if $\operatorname{supp} \chi_{v} \subset Q_{v}\left(a g_{v}\right.$-ball), and if $a(x, \xi)=a(x, \xi)$ on $Q_{v}^{*}$ ( the $g_{v}$-ball with same center and double radius), $a$ satisfying the estimates of $g_{v}$, we have

$$
\chi_{v} \sharp a \sharp \chi_{v}=\chi_{v} \sharp a \sharp \chi_{v}+\widetilde{r}_{v}, \quad \Sigma \widetilde{r}_{v}^{w} L^{2} \text { bounded. }
$$

We are consequently reduced to look at

$$
\begin{equation*}
a=\left(\eta_{1}-\alpha\left(y, \eta^{\prime}\right)\right)^{2} \lambda e_{0}(y, \eta)+b\left(y, \eta^{\prime}\right) \tag{3.3.1}
\end{equation*}
$$

that can be easily extended to $\mathbb{R}^{2 n}$ (and still satisfy the estimates).
For the reader's convenience, we state a version of the "Sharp Egorov Principle", proved by Fefferman and Phong in [6].

Theorem 3.7. - Let $g$ be a quadratic form on $\mathbb{R}^{2 n}$ such that $g=\lambda^{-1} \Gamma$, where $\lambda \geq 1$ and $\Gamma$ is a quadratic form such that $\Gamma=\Gamma^{\sigma}$ (see (3.7)).

Let $a \in S^{2}(g)$ real valued (i.e. $\left.\left|a^{(k)}(X) T^{k}\right| \leq \gamma_{k g}(a) \lambda^{2-\frac{k}{2}}\right)$ supported in $Q$, a $g$-ball of radius 1. Let $\chi$ be a canonical transformation $\chi: \mathbb{R}^{2 n} \rightarrow$ $\mathbb{R}^{2 n}$ such that $\chi^{*}(\sigma)=\sigma$ and

$$
\begin{align*}
&\left|\chi^{(k)}(X)\right|_{\Gamma} \leq \gamma_{k}(\chi) \lambda^{\frac{1}{2}-\frac{k}{2}}  \tag{3.31}\\
&\left|\chi^{\prime}(X)^{-1}\right|_{\Gamma} \leq \gamma_{1}(\chi)
\end{align*}
$$

Then, there exists a Fourier integral operator $U$, bounded on $L^{2}\left(\mathbb{R}^{n}\right)$ and $r \in S^{0}(g)$ so that the operator

$$
\begin{equation*}
a^{w}=U^{*}(a \circ \chi)^{w} U+r^{w} \tag{3.32}
\end{equation*}
$$

## 4. PSEUDO-DIFFERENTIAL OPERATORS IN ONE DIMENSION

## a. Preliminaries.

We wish to prove here a one-dimensional version of Fefferman and Phong's conjecture $\sharp 5$ in section 7 of [6]. As a matter of fact, we can prove here an inequality with gain of two full derivatives ( $\varepsilon=0$ with FeffermanPhong's notation). Let's set-up our framework. Let $G$ be an Hörmander metric (i.e. (3.6), (3.7), (3.8) are satisfied) such that $G_{X}=\Lambda(X)^{-1} \Gamma_{X}$, where $\Gamma_{X}=\Gamma_{X}^{\sigma}$ (see (3.7)) and $\Lambda(X) \geq 1$. Note that this is the case for the classical metric

$$
d x^{2}+\frac{d \xi^{2}}{\langle\xi\rangle^{2}}=\langle\xi\rangle^{-1}\left(\langle\xi\rangle d x^{2}+\langle\xi\rangle^{-1} d \xi^{2}\right), \quad\langle\xi\rangle^{2}=1+|\xi|^{2}
$$

We shall denote $g_{X}=\lambda(X)^{-1} \Gamma_{X}$ the proper conformal metric of a symbol $a$ ( $\lambda$ is defined in (3.13)). Our first assumption will be

$$
\begin{equation*}
\int_{X, \pi \Gamma_{Y}(X-Y) \leq 1} a(X) d X \geq 0 \text { for any } Y \in \mathbb{R}^{2 n} \tag{4.1}
\end{equation*}
$$

Moreover, using propositions 3.4 and 3.5 , since (4.1) implies (3.28), we are reduced to consider $g$-balls on which $\left(g=\lambda^{-1} \Gamma, \Gamma=d y^{2}+d \eta^{2}\right)$

$$
\begin{equation*}
a=\left(\eta-\lambda^{1 / 2} \alpha(y)\right)^{2} e_{0}(y, \eta) \lambda+W(y) \lambda^{2} \tag{4.2}
\end{equation*}
$$

with

$$
\begin{equation*}
\left|a^{(k)}(y)\right|+\left|e_{0}^{(k)}(y, \eta)\right|+\left|W^{(k)}(y)\right| \leq C_{k} \lambda^{-k / 2} \tag{4.3}
\end{equation*}
$$

and

$$
\begin{equation*}
e_{0}(y, \eta) \geq C_{1}^{-1}>0 \tag{4.4}
\end{equation*}
$$

Note also that, dividing the symbol $a$ by one of its semi-norm, we can assume that $\gamma_{k G}(a) \leq 1$ for $k \leq N_{0}$, with an arbitrary $N_{0}$, to be chosen.

Consequently, all the constants $C_{k}$ in (4.3) up to $k=\theta\left(N_{0}\right)(\theta(N) \rightarrow$ $\infty$ with $N$ ) are "universal constants".

It is an easy matter to extend the functions $\alpha, e_{0}, W$ to the whole $\mathbb{R}^{2 n}$, keeping their properties :

$$
\begin{gathered}
\widetilde{\alpha}(y)=\alpha(y) \psi\left(y \lambda^{-1 / 2}\right) \\
\psi \in C_{0}^{\infty}(\mathbb{R}), \psi \equiv 1 \text { on }(-2,+2) \\
0 \leq \psi \leq 1, \psi \equiv 0 \text { outside }(-3,+3)
\end{gathered}
$$

We define $\widetilde{e}_{0}(y, \eta)=e_{0}(y, \eta) \psi\left(\frac{y^{2}+\eta^{2}}{\lambda}\right)+\left(1-\psi\left(\frac{y^{2}+\eta^{2}}{\lambda}\right)\right)$ and $W(y)=$ $W(y) \psi\left(y \lambda^{-1 / 2}\right)$.

We get then that (4.2) is satisfied on $y^{2}+\eta^{2} \leq \lambda$, but with a righthand side so that (4.3) and (4.4) are still satisfied. In what follows we'll keep using the notation $\alpha, e_{0}, W$ dropping the $\sim$.

Let's use now the Egorov theorem (th. 3.7). We consider the canonical transformation $\chi^{-1}$ on $\mathbb{R}^{2}$

$$
\left\{\begin{array}{l}
\tau=\eta-\alpha(y)  \tag{4.5}\\
t=y
\end{array}\right.
$$

The estimates (3.31) are satisfied, and we get that

$$
a(\chi(t, \tau))=\lambda \tau^{2} e_{0}+\lambda^{2} W(t) \text { on } t^{2}+\tau^{2} \leq \lambda
$$

Consequently, from (3.32)

$$
\left((a \circ \chi)\left(\psi \circ \lambda^{-1} \Gamma \circ \chi\right)^{2}\right)^{w} \equiv U^{*}\left(a\left(\psi \circ \lambda^{-1} \Gamma\right)^{2}\right)^{w} U \text { modulo } \mathcal{L}\left(L^{2}\right)
$$

Moreover $a\left(\psi \circ \lambda^{-1} \Gamma\right)^{2}=\psi \circ \lambda^{-1} \Gamma \sharp a \sharp \psi \circ \lambda^{-1} \Gamma+r, r^{w} \in \mathcal{L}\left(L^{2}\right)$. So in order to check the non-negativity of $a^{w}$, we need only to check the one of

$$
\left[\left(\lambda \tau^{2} e_{0}+\lambda^{2} W(t)\right)\left(\psi \circ \lambda^{-1} \Gamma \circ \chi\right)^{2}\right]^{w}
$$

and thus eventually, because of the symbolic calculus, the one of $\lambda \tau^{2} e_{0}+$ $\lambda^{2} W(t)$.

## b. Statement of the result.

Let's introduce the following family of canonical transformations : $\chi \in \Phi$ if $\chi$ is $C^{\infty}$, canonical, and satisfies

$$
\left\{\begin{align*}
\left|\chi^{(k)}(X)\right|_{\Gamma_{X}} & \leq C_{k}(\chi) \lambda(X)^{\frac{1}{2}-\frac{k}{2}}  \tag{4.6}\\
g_{X}(\chi(X)-X) & \leq \delta_{0}
\end{align*}\right.
$$

where $\delta_{0} \leq C^{-1}$ in (3.6) for $g$.

We'll denote by $Q$ any symplectic unit cube of

$$
\mathbb{R}^{2}: Q=\{(t, \tau), \max (|t|,|\tau|) \leq 1\}
$$

for some linear symplectic coordinates.
Theorem 4.1. - There exists $C_{00}>0$ such that, if (4.1) is satisfied for $a \in S^{2}(G)$ such that

$$
\begin{equation*}
\int_{Q}(a \circ \chi) d X+C_{00} \inf _{Q}(a \circ \chi) \geq 0 \tag{4.7}
\end{equation*}
$$

for any symplectic cube $Q$ and any $\chi \in \Phi$, then

$$
\begin{equation*}
a^{w}+C \geq 0 \tag{4.8}
\end{equation*}
$$

where $C$ depends only on a fixed finite number of semi-norms of $a$.

Proof. - Using the preliminaries and a linear rescaling, it is enough to prove the non-negativity of $C_{1}^{-1} \tau^{2}+V(t)$ on functions supported in $|t| \leq 1$.

Using theorem 2.1 and remark 2.2 we need to check for $Q$ interval, $|Q| \leq 2, \quad Q \subset(0,3):|Q|^{-1} \int_{Q} C_{1} V(t) d t+|Q|^{-2} \geq 8|Q|^{-1} \int_{Q} C_{1} V_{-}(t) d t$. Since we can assume $a \circ \chi=e_{0} \tau^{2}+V(t)$ on $|t| \leq 4,|\tau| \leq \lambda$, we have from (4.7)

$$
\delta^{-2}+\delta^{-1} \int_{Q} V(t) d t \geq C_{00} \max _{t \in Q} V_{-}(t)
$$

and so

$$
C_{1} \delta^{-2}+\delta^{-1} \int_{Q} C_{1} V_{+}(t) d t \geq C_{00} \max _{t \in Q} C_{1} V_{-}(t)
$$

If $C_{00} \geq 9 C_{1}, C_{1} \geq 1$, we obtain

$$
\delta^{-2}+\delta^{-1} \int_{Q} C_{1} V_{+}(t) d t \geq 9 \max _{t \in Q} C_{1} V_{-}(t)
$$

so (2.1) is satisfied.
Since (4.7) and (4.1) are preserved by multiplication by a positive number, we get (4.8) for $\frac{a^{w}}{\gamma_{N}(a)}$ with a universal constant $C$. In particular $C_{00}$ can be chosen independently of the semi-norms of $a$.

The proof is complete.
