# HULLS OF SUBSETS OF THE TORUS IN $\mathbb{C}^{2}$ 

by Herbert ALEXANDER

## Introduction.

We consider in $\mathbb{C}^{2}$ the polynomial convex hull $\hat{X}$ of a compact subset $X$ of the unit torus $\mathbb{T}^{2}=\left\{(z, w) \in \mathbb{C}^{2}:|z|=1,|w|=1\right\}$. If a point $p$ in the open unit polydisk $\Delta^{2}$ is contained in a 1 -dimensional analytic subvariety $V$ of the polydisk and if $b V \subseteq X$, then the maximum principle implies that $p \in \hat{X}$. One can ask if the hull of $X \subseteq \mathbb{T}^{2}$ can be larger than $X$ without the existence of such a variety $V$ with $b V \subseteq X$. It is known that in general a polynomial hull need not contain such analytic structure: this was first demonstrated by G. Stolzenberg [S]. Subsequently John Wermer [W] gave an example of a set $X$ in $\mathbb{C}^{2}$ lying over the unit circle (i.e. $X \subseteq\left\{(z, w) \in \mathbb{C}^{2}:|z|=1\right\}$ ) such that $\hat{X}$ contains no analytic structure. Our main result here is that such a set can be found in $\mathbb{T}^{2}$.

Theorem. - There exists a compact subset $X$ of $\mathbb{T}^{2}$ such that $\hat{X} \backslash X$ is a non-empty subset of $\Delta^{2}$ and $\hat{X} \backslash X$ contains no analytic subset of positive dimension. Moreover, if $V$ is any pure 1-dimensional analytic subvariety of $\Delta^{2}$ with $b V \subseteq \mathbb{T}^{2}$ and $\Omega$ is any neighborhood of $\bar{V}$ in $\bar{\Delta}^{2}$, then we can choose $\hat{X}$ to be contained in $\Omega$.

Our proof is parallel to Wermer's [W]-however the details differ because we need to construct varieties with boundaries in $\mathbb{T}^{2}$ and consequently, the linear structure in the $w$-variable, which underlies Wermer's

[^0]construction, cannot be used here. Instead, in order to keep the boundaries in $\mathbb{T}^{2}$, we iterate the composition of proper holomorphic correspondences. The first step is to obtain a good explicit approximation to the identity. The "identity" correspondence in this case being the diagonal variety $\{z=w\}$ in $\Delta^{2}$. Our approximation is by a subvariety $V^{\epsilon}$ that "doubles" the identity and that satisfies $b V^{\epsilon} \subseteq \mathbb{T}^{2} ; V^{\epsilon}$ approaches the identity in the Hausdorff metric as $\epsilon \rightarrow 0$. The set $X$ is then obtained essentially as a limit of iterates of the $V^{\epsilon}$ for a sequence of $\epsilon$ 's approaching 0 .

The method of Stolzenberg mentioned above is based on a different type of construction. This has been further developed in recent work of Fornaess and Levenberg [FL] and Duval and Levenberg [DL]. Davidson and Salinas [DS] have applied the theory of hulls of subsets $X$ of $\mathbb{T}^{2}$ to study operator theoretical variants of $\operatorname{Ext}(X)$.

## 1. Preliminary remarks and notations.

(a) Notations. - We will denote a point of $\mathbb{C}^{2}$ by $(z, w)$ and denote the two coordinate functions by $z$ and $w$. We put $\Delta(\beta, r)=\{z \in \mathbb{C}$ : $|z-\beta|<r\}$ and write $\Delta^{\prime}(\beta, r)=\{z \in \mathbb{C}: 0<|z-\beta|<r\}$ for the punctured disk. $\Delta$ denotes the open unit disk and $\Delta^{2}$ the unit polydisk in $\mathbb{C}^{2}$ with the unit torus $\mathbb{T}^{2}=\{(z, w):|z|=1,|w|=1\}$, as its distinguished boundary. Recall that the polynomially convex hull of a compact set $X \subseteq \mathbb{C}^{n}$ is the set

$$
\hat{X}=\left\{z \in \mathbb{C}^{n}:|P(z)| \leq\|P\|_{X} \text { for all polynomials } P \text { in } \mathbb{C}^{n}\right\}
$$

where $\|P\|_{X}$ is the supremum of $|P|$ over $X$. For a subset $Z$ of $\mathbb{C}^{2}$ we denote the fiber of $Z$ by the map $z$ over the point $\lambda \in \mathbb{C}$ by $Z_{\lambda}$, this is defined as the set $\{w \in \mathbb{C}:(\lambda, w) \in Z\}$.
(b) Semicontinuity of the hull. - We recall that the operation of taking the polynomially hull of $X$ is "semi-continuous" in the sense that for all open sets $\mathcal{W} \supseteq \hat{X}$ there exists an open set $\mathcal{V} \supseteq X$ such that $\hat{K} \subseteq \mathcal{W}$ provided that $K \subseteq \mathcal{V}$. We shall often use this fact below without an explicit reference.
(c) Composition of holomorphic correspondences. - Let $V$ be a pure 1-dimensional subvariety of the polydisk $\Delta^{2}$ with $b V \subseteq \mathbb{T}^{2}$. This class of varieties can also be described as the set of proper holomorphic
correspondences of the disk $\Delta$ with itself. See K. Stein [St] for a general discussion. For these correspondences there is an operation of composition that can be described as follows: if $V_{1}$ is given locally by functions $w=$ $W_{1}^{k}(z), 1 \leq k \leq m_{1}$ and and $V_{2}$ is given locally by functions $w=W_{2}^{j}(z)$, $1 \leq j \leq m_{2}$, then the composition $V_{1} \circ V_{2}$ is given locally by the $m_{1} m_{2}$ functions $W_{1}^{k} \circ W_{2}^{j}$. In particular, identifying a function with its graph, if these correspondences are functions (i.e., $m_{1}=1, m_{2}=1$ ), then this is just the usual composition of functions. For us the main point is that the family of pure 1-dimensional subvarieties $V$ of the polydisk $\Delta^{2}$ with $b V \subseteq \mathbb{T}^{2}$ (i.e. the class of proper holomorphic correspondences) is closed under composition. The varieties that we construct below will be of the form $V_{1} \circ V_{2} \circ \cdots \circ V_{n}$. We remark that Slodkowski [Sl] has proved more generally that the composition of analytic multifunctions is (when defined) also an analytic multifunction. We shall not need this here.

## 2. Approximation of the identity.

We want to approximate the diagonal $\{w=z\}$ in $\Delta^{2}$ by a subvariety of $\Delta^{2}$ with boundary in $\mathbb{T}^{2}$. More precisely we approximate the diagonal with multiplicity two, $\left\{(w-z)^{2}=0\right\}$, by an irreducible subvariety of $\Delta^{2}$ with boundary in $\mathbb{T}^{2}$. To do this we shall modify the coefficients of lower order powers of $w$ in the defining equation

$$
\begin{equation*}
w^{2}-2 z w+z^{2}=0 \tag{1}
\end{equation*}
$$

We construct a family $\left\{V^{\epsilon}\right\}$ of such subvarieties depending on a positive parameter $\epsilon, 0<\epsilon<1$. We define $V^{\epsilon}$ as the set of all $(z, w) \in \mathbb{C}^{2}$ with $|z|<1$ and satisfying the equation

$$
\begin{equation*}
w^{2}-2 A_{\epsilon}(z) w+B(z)=0 \tag{2}
\end{equation*}
$$

where

$$
\begin{equation*}
A_{\epsilon}(z)=(1-\epsilon)\left(z-\epsilon^{2}\right) \tag{3}
\end{equation*}
$$

and

$$
\begin{equation*}
B_{\epsilon}(z)=z \frac{z-\epsilon^{2}}{1-\epsilon^{2} z} \tag{4}
\end{equation*}
$$

We shall see below that $V^{\epsilon} \subseteq \Delta^{2}$. Note that as $\epsilon \rightarrow 0, A_{\epsilon}(z) \rightarrow z$ and $B_{\epsilon}(z) \rightarrow z^{2}$ and so the coefficients of the powers of $w$ on the left hand side of the equation (2) approach the corresponding coefficients of the powers
of $w$ on the left hand side of the equation (1). The main point here, which requires some computations, is that $b V^{\epsilon}=\overline{V^{\epsilon}} \backslash V^{\epsilon} \subseteq \mathbb{T}^{2}$.

Note that for $|z|=1$,

$$
\begin{equation*}
\left|A_{\epsilon}(z)\right| \leq(1-\epsilon)\left(1+\epsilon^{2}\right)<1 \tag{5}
\end{equation*}
$$

and that

$$
\begin{equation*}
\left|B_{\epsilon}(z)\right|=1 \tag{6}
\end{equation*}
$$

since $B_{\epsilon}$ is a finite Blaschke product. Define a rational function $g_{\epsilon}$ of $z$ by

$$
\begin{equation*}
g_{\epsilon}(z)=\frac{B_{\epsilon}}{A_{\epsilon}^{2}}=\frac{z}{(1-\epsilon)^{2}\left(1-\epsilon^{2} z\right)\left(z-\epsilon^{2}\right)} . \tag{7}
\end{equation*}
$$

Lemma 1. - On the unit circle $\mathbb{T}$, $g_{\epsilon}$ is real-valued, positive and satisfies

$$
\begin{equation*}
g_{\epsilon}=\left|g_{\epsilon}\right|>1 \tag{8}
\end{equation*}
$$

Proof. - By a direct computation one shows that $\overline{g_{\epsilon}(z)}=g_{\epsilon}(z)$ for $|z|=1$ (multiply on the left by $z^{2}$ in the numerator and denominator). And so $g_{\epsilon}$ is real-valued on $\mathbb{T}$. Also

$$
\begin{equation*}
\left|g_{\epsilon}\right|=\frac{\left|B_{\epsilon}\right|}{\left|A_{\epsilon}\right|^{2}}=\frac{1}{\left|A_{\epsilon}\right|^{2}}>1 \tag{9}
\end{equation*}
$$

on $\mathbb{T}$ by (5), (6) and (7). Hence $g_{\epsilon}(z)>1$ or $g_{\epsilon}(z)<-1$ at each $z \in \mathbb{T}$. Finally since $g_{\epsilon}(1)>1$ we conclude, by the connectedness of $\mathbb{T}$, that (8) holds on $\mathbb{T}$.

Define a function $h_{\epsilon}$ on $\mathbb{T}$ by

$$
h_{\epsilon}=\sqrt{g_{\epsilon}-1}
$$

By Lemma 1, we can choose the square root so that $h_{\epsilon}$ is real and positive on $\mathbb{T}$. Then clearly $h_{\epsilon}$ extends to be holomorphic in a neighborhood of $\mathbb{T}$. Now we solve the equation (2) for $w$ and get

$$
\begin{equation*}
w=A_{\epsilon} \pm \sqrt{A_{\epsilon}^{2}-B_{\epsilon}} . \tag{10}
\end{equation*}
$$

By (7) $B_{\epsilon}=A_{\epsilon}^{2} g_{\epsilon}$ and we have $A_{\epsilon}^{2}-B_{\epsilon}=A_{\epsilon}^{2}\left(1-g_{\epsilon}\right)=-A_{\epsilon}^{2} h_{\epsilon}^{2}$. We get

$$
w=A_{\epsilon} \pm i A_{\epsilon} h_{\epsilon}
$$

for $z$ in some neighborhood of $\mathbb{T}$. For $z \in \mathbb{T}$ we get

$$
w=A_{\epsilon}\left(1 \pm i h_{\epsilon}\right)
$$

and so, since $h_{\epsilon}$ is positive on $\mathbb{T}$, on $\mathbb{T}$ we have:

$$
\begin{equation*}
|w|=\left|A_{\epsilon}\right|\left|1 \pm i h_{\epsilon}\right|=\left|A_{\epsilon}\right| \sqrt{1+h_{\epsilon}^{2}}=\left|A_{\epsilon}\right| \sqrt{\left|g_{\epsilon}\right|}=\left|A_{\epsilon}\right| \frac{1}{\left|A_{\epsilon}\right|}=1 . \tag{11}
\end{equation*}
$$

From (11) we conclude that $b V^{\epsilon} \subseteq \mathbb{T}^{2}$.
Consider the discriminant $D_{\epsilon}=A_{\epsilon}^{2}-B_{\epsilon}$ of (2). By (5) and (6) $D_{\epsilon}$ has no zeros on $\mathbb{T}$. We claim that $D_{\epsilon}$ has two distinct zeros in the unit disk. Since $B_{\epsilon}$ has two zeros in the unit disk it follows from Rouché's theorem that $D_{\epsilon}$ also has two zeros in the unit disk, provided that $\left|D_{\epsilon}+B_{\epsilon}\right|<\left|B_{\epsilon}\right|$ on $\mathbb{T}$. This last inequality follows from (5) and (6), since $\left|D_{\epsilon}+B_{\epsilon}\right|=\left|A_{\epsilon}\right|^{2}<1=\left|B_{\epsilon}\right|$ on $\mathbb{T}$. We want we locate the two zeros of $D_{\epsilon}$ in $\Delta$ more precisely. One of these zeros is $\epsilon^{2}$. We claim that the other zero in the unit disk is in the real interval $(-\epsilon, 0)$. Write $D_{\epsilon}=\left(z-\epsilon^{2}\right) H_{\epsilon}(z)$ where

$$
H_{\epsilon}(z)=(1-\epsilon)^{2}\left(z-\epsilon^{2}\right)-\frac{z}{1-\epsilon^{2} z}
$$

In fact clearly $H_{\epsilon}(0)<0$ and so we need only show that $H_{\epsilon}(-\epsilon)>0$. By a short calculation, $\left(\left(1+\epsilon^{3}\right) / \epsilon\right) H_{\epsilon}(-\epsilon)=1-(1-\epsilon)^{2}(1+\epsilon)\left(1+\epsilon^{3}\right)>0$.

Our constructions below will be based on the varieties $V^{\epsilon}$. The next result collects the facts that we shall need.

Proposition 2. - The equation (2) defines subvarieties $V^{\epsilon}$ of $\Delta^{2}$ with the following properties:
(a) The boundary $b V^{\epsilon}$ of $V^{\epsilon}$ is contained in the torus $\mathbb{T}^{2}$ and consists of two disjoint simple closed real curves each of which is mapped by the coordinate function $z$ diffeomorphically to $\mathbb{T}$.
(b) The map $z: V^{\epsilon} \rightarrow \Delta$ is a branched analytic cover of order 2. There are precisely two points in $\Delta$ over which the mapping branches: $\epsilon^{2}$ is one of these points and the second point lies on the negative real axis in the interval $(-\epsilon, 0)$.
(c) The sets $\overline{V^{\epsilon}}$ converge in the Hausdorff metric to the diagonal set $\left\{(z, w) \in \overline{\Delta^{2}}: z=w\right\}$ as $\epsilon \rightarrow 0$.
Moreover let $V$ be a pure 1-dimensional subvariety of $\Delta^{2}$ with $b V \subseteq \mathbb{T}^{2}$ and let $\mathcal{U}$ be a neighborhood of $b V$ in $\mathbb{T}^{2}$. If $\epsilon$ is sufficiently small, then $b\left(V \circ V^{\epsilon}\right) \subseteq \mathcal{U}$.

Remark. - As we have noted above, $V \circ V^{\epsilon}$ is a subvariety of $\Delta^{2}$ with $b\left(V \circ V^{\epsilon}\right) \subseteq \mathbb{T}^{2}$.

Proof. - The $V^{\epsilon}$ are defined as subvarieties of $\Delta \times \mathbb{C}$ and are clearly bounded sets. We have seen above that for $(z, w) \in V^{\epsilon},(z, w) \rightarrow \mathbb{T}^{2}$ as $|z| \rightarrow 1$. Thus we can apply the maximum principle to the function $w$ on $V^{\epsilon}$ to conclude that $|w|<1$ on $V^{\epsilon}$; i.e., $V^{\epsilon} \subseteq \Delta^{2}$.

By the discussion above, $b V^{\epsilon} \subseteq \mathbb{T}^{2}$ is the union of the two curves $\left\{\left(z, A_{\epsilon}(z)\left(1+i h_{\epsilon}(z)\right)\right): z \in \mathbb{T}\right\}$ and $\left\{\left(z, A_{\epsilon}(z)\left(1-i h_{\epsilon}(z)\right)\right): z \in \mathbb{T}\right\}$. Since $h_{\epsilon} \neq 0$ on $\mathbb{T}$, the two curves are disjoint. This gives part (a). We have shown above that $D_{\epsilon}$ has precisely the two zeros in $\Delta$ that are given in (b). Since $A_{\epsilon}(z) \rightarrow z$ and $B_{\epsilon}(z) \rightarrow z^{2}$ uniformly on $\bar{\Delta}$ as $\epsilon \rightarrow 0$, (c) follows from the explicit formula (10) for $V^{\epsilon}$.

Finally the fact that $b\left(V \circ V^{\epsilon}\right) \subseteq \mathcal{U}$ for small enough $\epsilon$ follows directly from (c).

Remark. - The varieties $V^{\epsilon}$ that we have used to approximate the diagonal are annuli such that $b V^{\epsilon}$ is a union of two disjoint simple closed curves in $\mathbb{T}^{2}$. The referee has pointed out a different approximation parameterized by the unit disk by the map $\lambda \mapsto\left(\lambda^{2}, \lambda(\lambda-\epsilon) /(1-\epsilon \lambda)\right)$. The boundaries of these disks are single curves in $\mathbb{T}^{2}$ with one self-intersection. (Any sufficiently good approximation to the diagonal by a disk will have such a self- intersection at the boundary.) These disks could be used in place of the $V^{\epsilon}$ in an appropriate version of Proposition 2 and then, without further changes, in our proof of the theorem.

## 3. The doubling lemma.

The next lemma gives an approximation of a given variety by one with twice the number of sheets and introduces branching over a given point.

Lemma 3. - Let $V$ be a pure one-dimensional analytic subvariety of $\Delta^{2}$ with $b V \subseteq \mathbb{T}^{2}$ so that $z: V \rightarrow \Delta$ is a branched cover of order $m$. Let $\mathcal{U} \subseteq \mathbb{T}^{2}$ be an open neighborhood of $b V$ in $\mathbb{T}^{2}$. Let $\lambda \in \Delta$ be a point over which $V$ is not branched. We can thus choose $s$ so that $V \cap z^{-1}(\Delta(\lambda, s))$ is the union of $m$ components each of which is mapped biholomorphically by $z$ to $\Delta(\lambda, s)$. Assume further that : $\left(^{*}\right) w$ maps these $m$ components biholomorphically to mutually disjoint open subsets in $\mathbb{C}$. Then for all sufficiently small $\epsilon>0$ there exists a pure one-dimensional analytic subvariety $W$ of $\Delta^{2}$ with $b W \subseteq \mathbb{T}^{2}$ such that
(a) $b W \subseteq \mathcal{U}$
and, setting $\beta=\left(\lambda+\epsilon^{2}\right) /\left(1+\epsilon^{2} \lambda\right)$,
(b) there exists $r>0$ with $\overline{\Delta(\beta, r)} \subseteq \Delta(\lambda, s)$ and such that

$$
W \cap z^{-1}(b \Delta(\beta, r))=\gamma_{1} \cup \gamma_{2} \cup \cdots \cup \gamma_{m}
$$

with each $\gamma_{j}$ a (connected) Jordan curve such that $z: \gamma_{j} \rightarrow b \Delta(\beta, r)$ is a 2-to-1 covering projection.

Proof. - We consider first the case $\lambda=0$. We define the variety $W$ to be the composition $V \circ V^{\epsilon}$. If $\epsilon$ is sufficiently small then (a) holds.

By hypothesis there are $m$ single-valued analytic functions $w_{1}, w_{2}, \cdots, w_{m}$ in $\Delta(0, s)$ so that $V \cap z^{-1}(\Delta(0, s))$ is the union of the graphs of these $m$ functions.

Recall that $V^{\epsilon}$ is given by the two locally defined function $w_{1}^{\epsilon}, w_{2}^{\epsilon}$. Let $\Delta^{\prime}$ be the punctured disk $\Delta^{\prime}\left(\epsilon^{2}, \epsilon^{2} / 2\right)$. A germ of $w_{1}^{\epsilon}$ at any point of $\Delta^{\prime}$ can be analytically continued around every path in $\Delta^{\prime}$. Moreover, by the construction of $V^{\epsilon}$, such analytic continuation of $w_{1}^{\epsilon}$ once around a circle in $\Delta^{\prime}$ about 0 yields the different germ $w_{2}^{\epsilon}$. Thus, over $\Delta^{\prime}, V^{\epsilon}$ is a connected double cover without branching locus; i.e., $z: V^{\epsilon} \cap z^{-1}\left(\Delta^{\prime}\right) \rightarrow \Delta^{\prime}$ a covering projection of order two and $V^{\epsilon} \cap z^{-1}\left(\Delta^{\prime}\right)$ is connected. If $\epsilon$ is sufficiently small, the range of (all continuations in $\Delta^{\prime}$ of ) $w_{1}^{\epsilon}$ lies in $\Delta(0, s)$.

Consider the (multiple-valued) functions $w_{j} \circ w_{1}^{\epsilon}$ in $\Delta^{\prime}$. Each can be analytically continued on all paths in $\Delta^{\prime}$. We claim that such analytic continuation of $w_{j} \circ w_{1}^{\epsilon}$ once around a circle in $\Delta^{\prime}$ about 0 yields a different germ (i.e., gives rise to a two-valued function). Otherwise, continuation would lead back to the same germ (since by (*) the $m$ sets $w_{k}(\Delta(0, s))$ are mutually disjoint for $1 \leq k \leq m$ ). But this implies, by applying the inverse of $w_{j}$ (which exists by $\left(^{*}\right)$ ), that analytic continuation of $w_{1}^{\epsilon}$ once around a circle in $\Delta^{\prime}$ about 0 yields the same germ-a contradiction. This gives the claim. Since $W$ is $2 m$-sheeted, we conclude from the claim that $W \cap z^{-1}\left(\Delta^{\prime}\right)$ is the union of $m$ connected components, each of which is an unbranched double covering of $\Delta^{\prime}$. Hence the lemma holds in the case $\lambda=0$ with $\beta=\epsilon^{2}$ and for any $r$ with $0<r<\epsilon^{2} / 2$.

Next we consider the general case $\lambda \in \Delta$. For $\alpha \in \Delta$, set

$$
\phi_{\alpha}(z)=\frac{z+\alpha}{1+\bar{\alpha} z}
$$

for $z \in \mathbb{C}$, and let

$$
L_{\alpha}(z, w)=\left(\phi_{\alpha}(z), w\right)
$$

$L_{\alpha}$ is a biholomorphism of $\Delta^{2}$. We apply the previous case, taking $V_{1}=$ $L_{-\lambda}(V)$ for $V$ and $\mathcal{U}_{1}=L_{-\lambda}(\mathcal{U})$ for $\mathcal{U}$. Since $\phi_{-\lambda}(\lambda)=0, V_{1}$ is unbranched over 0 . The previous case gives, for $\epsilon$ sufficiently small, that $W_{1}=$ $L_{-\lambda}(V) \circ V^{\epsilon}$ satisfies $b W_{1} \subseteq \mathcal{U}_{1}$ and that $W_{1}$ also has the appropriate branching behavior near $z=\epsilon^{2}$. Finally we let $W=L_{\lambda}\left(W_{1}\right)$. Since $L_{\lambda} \circ L_{-\lambda}=$ identity, we have $b W \subseteq \mathcal{U}$ and (b) holds with $\beta=\phi_{\lambda}\left(\epsilon^{2}\right)=$ $\left(\lambda+\epsilon^{2}\right) /\left(1+\epsilon^{2} \lambda\right)$. Indeed for $\epsilon$ sufficiently small, $\phi_{\lambda}\left(\epsilon^{2}\right) \in \Delta(\lambda, s)$ and from the previous case we conclude that over a small deleted neighborhood of $\beta$, $W$ is the union of $m$ connected components, each of which is an unbranched double covering. This gives the lemma.

## 4. Proof of the theorem.

Lemma 4. - Let $W$ be a pure 1-dimensional analytic subvariety of $\Delta^{2}$ with $b W \subseteq \mathbb{T}^{2}$ and let $\Delta(\beta, r)$ be a disk with closure contained in $\Delta$. Suppose that $W \cap z^{-1}(b \Delta(\beta, r))$ is the disjoint union of $N$ smooth Jordan (connected!) curves $\gamma_{1}, \gamma_{2}, \cdots, \gamma_{N}$ such that $z: \gamma_{j} \rightarrow b \Delta(\beta, r)$ is a covering projection of order $n_{j}>1$ for each $j=1,2, \cdots, N$. Then there exists a neighborhood $\mathcal{U}$ of $b W$ in $\mathbb{T}^{2}$ with the following property: if $X$ is compact with $X \subseteq \mathcal{U} \subseteq \mathbb{T}^{2}$, then $\hat{X}$ has no continuous sections over $b \Delta(\beta, r)$; i.e., there does not exist a continuous complex valued function $f$ defined on $b \Delta(\beta, r)$ such that $\operatorname{Gr}(f) \equiv\{(\lambda, f(\lambda)): \lambda \in b \Delta(\beta, r)\} \subseteq \hat{X}$.

Proof. - We can view each $\gamma_{j}$ as a submanifold of $b \Delta(\beta, r) \times \mathbb{C}$. Let $\mathcal{N}_{j}$ be a small tubular neighborhood of $\gamma_{j}$ in $b \Delta(\beta, r) \times \mathbb{C}$ with the $z$-coordinate constant on the fibers of this tubular neighborhood (viewing the tubular neighborhood as a normal bundle). Let $\rho_{j}: \mathcal{N}_{j} \rightarrow \gamma_{j}$ be the projection along the fibers; in particular, we have $z\left(\rho_{j}\left(z_{1}, z_{2}\right)\right)=z_{1}$. We can choose the $\mathcal{N}_{j}$ to be disjoint, $j=1,2, \cdots, N$. For all sufficiently small neighborhoods $\mathcal{U}$ of $b W$ in $\mathbb{T}^{2}, X \subseteq \mathcal{U}$ implies that $\hat{X} \cap(b \Delta(\beta, r) \times \mathbb{C}) \subseteq$ $\cup_{j=1}^{N} \mathcal{N}_{j}$; this is because $\widehat{b W} \cap(b \bar{\Delta}(\beta, r) \times \mathbb{C})=W \cap(b \Delta(\beta, r) \times \mathbb{C}) \subseteq$ $\cup_{j=1}^{N} \mathcal{N}_{j}$. Fix such a $\mathcal{U}$. Suppose that $X \subseteq \mathcal{U}$. Arguing by contradiction, suppose that there is a continuous complex valued function $f$ defined on $b \Delta(\beta, r)$ such that $\operatorname{Gr}(f) \equiv\{(\lambda, f(\lambda)): \lambda \in b \Delta(\beta, r)\} \subseteq \hat{X}$. Then $\operatorname{Gr}(f) \subseteq \cup_{j=1}^{N} \mathcal{N}_{j}$. By the connectedness of $\operatorname{Gr}(f), \operatorname{Gr}(f) \subseteq \mathcal{N}_{k}$, for some $k$, $1 \leq k \leq N$. Set $g(\lambda)=\rho_{k}((\lambda, f(\lambda)))$. Then $g$ is a continuous section of the covering projection (of order $n_{k}$ ) $z: \gamma_{k} \rightarrow b \Delta(\beta, r)$. Since $\gamma_{k}$ is connected and $n_{k}>1$, this is a contradiction.

Choose a dense sequence $\left\{\alpha_{n}^{\prime}\right\}$ in $\Delta$ and let $\left\{\alpha_{n}\right\}$ be a sequence in $\Delta$ in which each $\alpha_{k}^{\prime}$ is repeated infinitely often. Choose $\delta_{n}>0$ such that $\delta_{n}<1-\left|\alpha_{n}\right|$ and $\delta_{n} \rightarrow 0$. Set $\Delta_{n}=\Delta\left(\alpha_{n}, \delta_{n}\right)$. We construct three sequences for $n \geq 0$ : a sequence of subvarieties $\left\{V_{n}\right\}$ of $\Delta^{2}$ with $b V_{n} \subseteq \mathbb{T}^{2}$, a sequence of compact subsets $\left\{X_{n}\right\}$ of $\mathbb{T}^{2}$ and a sequence of disks $\Delta\left(\beta_{n}, r_{n}\right)$ such that
(a) $b V_{n} \subseteq$ the interior in $\mathbb{T}^{2}$ of $X_{n}$ for $n \geq 1$.
(b) $X_{0} \supseteq X_{1} \supseteq X_{2} \supseteq \cdots \supseteq X_{n} \supseteq \cdots$
(c) The diameters of the components of the fibers $\left(\hat{X}_{n}\right)_{z}$ of $\hat{X}_{n}$ are less that $1 / n$ for each $n \geq 1$ and each $z \in \bar{\Delta}$.
(d) For $n \geq 1, \overline{\Delta\left(\beta_{n}, r_{n}\right)} \subseteq \Delta_{n} \subseteq \Delta$ is such that there is no continuous section of the map $z: \widehat{X_{n}} \cap z^{-1}\left(b \Delta\left(\beta_{n}, r_{n}\right)\right) \rightarrow b \Delta\left(\beta_{n}, r_{n}\right)$; i.e., there does not exist a continuous complex valued function defined on $b \Delta\left(\beta_{n}, r_{n}\right)$ with graph contained in $\widehat{X_{n}}$.

Construction. - For the sake of a uniform notation we set $V_{0}=V$, $\Delta\left(\beta_{0}, r_{0}\right)=\Delta(0,1)$. We also choose $X_{0}$ to be a sufficiently small compact neighborhood of $b V$ in $\mathbb{T}^{2}$ so that $\hat{X}_{0} \subseteq \Omega$-this is possible since $V \cup b V=$ $\widehat{b V} \subseteq \Omega$. We proceed by induction. We assume that we have already defined $V_{0}, V_{1}, V_{2}, \cdots, V_{n-1}$ and $\Delta\left(\beta_{0}, r_{0}\right), \Delta\left(\beta_{1}, r_{1}\right), \Delta\left(\beta_{2}, r_{2}\right), \cdots, \Delta\left(\beta_{n-1}, r_{n-1}\right)$ and $X_{0}, X_{1}, X_{2}, \cdots, X_{n-1}$ and that this data satisfies (a)-(d) up to index $n-1$. Then, for $n \geq 1$, we define (i) $\Delta\left(\beta_{n}, r_{n}\right)$, (ii) $V_{n}$ and (iii) $X_{n}$. Choose a point $\lambda_{n} \in \Delta_{n}$ such that $V_{n-1}$ is unramified over $\lambda_{n}$. By moving $\lambda_{n}$ slightly, we can arrange so that $\left(^{*}\right)$ of Lemma 3 also holds. For sufficiently small $\epsilon$, Lemma 3, applied to $V_{n-1}$, yields a variety $W, \beta_{n}$ and $r_{n}$ such $\Delta\left(\beta_{n}, r_{n}\right) \subseteq$ $\Delta_{n}, b W \subseteq \operatorname{int}\left(X_{n-1}\right)$ (since $b V_{n-1} \subseteq \operatorname{int}\left(X_{n-1}\right)$ by the induction hypothesis) and such that the map $z: W \cap z^{-1}\left(b \Delta\left(\beta_{n}, r_{n}\right)\right) \rightarrow b \Delta\left(\beta_{n}, r_{n}\right)$ is a union of irreducible double covers. We take $V_{n}=W$. By Lemma 4 there exists a neighborhood $\mathcal{U}$ of $b V_{n}$ in $\mathbb{T}^{2}$ such that: $\mathcal{U} \subseteq \operatorname{int}\left(X_{n-1}\right)$ and if $K$ is a compact subset of $\mathcal{U}$ then $\hat{K}$ has no continuous section over $b \Delta\left(\beta_{n}, r_{n}\right)$. Now take $X_{n}$ to be a compact neighborhood of $b V_{n}$ with $X_{n} \subseteq \mathcal{U}$ and we get (a), (b) and (d). Moreover since the fibers of $\widehat{b V_{n}}=b V_{n} \cup V_{n}$ are finite, by taking $X_{n}$ to be a sufficiently small neighborhood of $b V_{n}$, it follows that the connected components of the fibers of $\widehat{X_{n}}$ each have diameter less that $1 / n$. This gives (c) and completes the construction.

Continuing the proof of the theorem, we let $X=\bigcap_{n=1}^{\infty} X_{n}$. Then
$\hat{X}=\bigcap_{n=1}^{\infty} \widehat{X_{n}}$. Hence $\hat{X} \subseteq \Omega$, since $\widehat{X_{0}} \subseteq \Omega$. Also $\hat{X} \backslash X$ is non-empty. To see this note that $\hat{X} \cap\{z=0\}$ is the intersection of the sets $\widehat{X_{n}} \cap\{z=0\}$. And these sets are non-empty since $\widehat{X_{n}} \cap\{z=0\} \supseteq V_{n} \cap\{z=0\} \neq \emptyset$.

Finally we need to show that $\hat{X} \backslash X$ does not contain analytic structure. We argue by contradiction and suppose that $\hat{X} \backslash X$ contains a 1-dimensional analytic set $A$. We can assume that $A$ is connected. Then $z(A)$ is open in $\mathbb{C}$. For if not, then $z \mid A$ is constant $\equiv z_{0}$. Hence $A$ is contained in the set $\hat{X}_{z_{0}}$, which is totally disconnected by (c)-a contradiction.

Thus we can choose a regular point $p \in A$ so that $z$ maps a neighborhood of $p$ in $A$ biholomorphically to an open set $\omega$ in $\Delta$. Hence there is an analytic function $f$ on $\omega$ whose graph is in $A$. There exists $n$ such that $\overline{\Delta_{n}} \subseteq \omega$. This is because $\delta_{n} \rightarrow 0$ and each $\alpha_{n}^{\prime}$ is repeated infinitely often in $\left\{\alpha_{n}\right\}$. Hence $\overline{\Delta\left(\beta_{n}, r_{n}\right)} \subseteq \omega$. Then $f$ gives a section of $\hat{X}$ over $b \Delta\left(\beta_{n}, r_{n}\right)$. Hence $f$ gives a section of $\widehat{X_{n}} \supseteq \hat{X}$ over $b \Delta\left(\beta_{n}, r_{n}\right)$. This is a contradiction of (d) and gives the theorem.

## 5. Concluding comments.

If the variety $V$ in the theorem is assumed to be irreducible, then the set $X \subseteq \mathbb{T}^{2}$ constructed in the proof is a minimal set having a non-empty hull without analytic structure. Minimal here means that every proper closed subset of $X$ is polynomially convex. We omit the straightforward proof.

By a well-known result of B. Shiffman [Sh], a (pure one-dimensional) subvariety of $\Delta^{2}$ with boundary in $\mathbb{T}^{2}$ can be reflected across $\mathbb{T}^{2}$ to yield a subvariety of $\mathbb{C}^{2}$ (or of $\mathbb{P}^{2}$ ). The local version was given in $[\mathrm{A}]$. In fact, this reflection procedure works more generally for pseudoconcave subsets $Z$ of $\Delta^{2}$ with boundary in $\mathbb{T}^{2}$. Namely, the set $\bar{Z} \cup \tau(Z)$ is pseudoconcave across $\mathbb{T}^{2}$, where $\tau$ is the reflection map $\tau((z, w))=(1 / \bar{z}, 1 / \bar{w})$. The local version also holds. This pseudoconcavity across $\mathbb{T}^{2}$ can be shown by adapting the proof of the Lemma in [A], in part, by replacing the use of the maximum principle by the use of the local maximum modulus principle. In particular, we can apply reflection to sets $Z=\Delta^{2} \cap \hat{X}$ for $X$ a compact subset of $\mathbb{T}^{2}$. More specifically the varieties $V_{n}$ and the sets $X_{n}$ and $X$ constructed in the proof of the Theorem can be reflected across $\mathbb{T}^{2}$. The convergence of $X_{n}$ to $X$ on $\Delta^{2}$ clearly extends to convergence, on compact subsets of $\mathbb{C}^{n}$, of the sets extended by reflection.

Duval and Sibony [DSib] employed Wermer's example [W] to produce extreme points in the cone of positive closed $(1,1)$ currents on $\mathbb{P}^{2}$ such that these extreme points have no analytic structure in their supports. (First Demailly [D] found extreme points that were not supported by algebraic varieties.) Their construction requires a Wermer set given in all of $\mathbb{C}^{2}$, not just in the polydisk. As noted in the previous paragraph, by reflecting in $\mathbb{T}^{2}$, the constructions of the present paper yield sets where the convergence in all of $\mathbb{C}^{2}$ is evident.
