# IDELE CHARACTERS <br> IN SPECTRAL SYNTHESIS ON R/2 $\pi \mathbf{Z}$ 

by John J. BENEDETTO

## Introduction.

The starting point for this paper is Malliavin's construction of real-valued absolutely convergent Fourier series $\varphi$ on $\mathbf{T}=\mathbf{R} / 2 \pi \mathbf{Z}$ having a non-synthesizable zero set, $\mathrm{Z} \varphi$ (§ 0.1 will contain relevant definitions and background in spectral synthesis). The construction of such a $\varphi$ by Richards [7] has led us to consider families of functions parameterized by $s=\sigma+i \tau \in \mathbf{G}, \sigma>1$, and having the form

$$
\begin{equation*}
\mathrm{F}(s, x)=\sum_{n=1}^{\infty} e^{i k_{n} x} / n^{s} \tag{1}
\end{equation*}
$$

that is, for fixed $s, \sigma>1$, the corresponding $\varphi=\varphi_{s}$ is $\varphi_{s}(x)=\operatorname{ReF}(s, x)$. The Dirichlet series (1) are discussed in § 1 and the results concerning the corresponding non-synthetizable $\varphi$ are proved in § 2. Because of these results we pose the "abscissa of spectral synthesis» problem at the end of § 2.

Since the above construction of non-synthesizable $\varphi_{s}$ involves no arithmetic properties of the $k_{n}$, it seemed reasonable to investigate properties of $\varphi_{s}$ when the corresponding F was generated from an idele character. We've only considered $\hat{\mathbf{J}}_{\mathbf{Q}}$ (see § 0.2), and have shown that those $\varphi_{s}$ generated by «slow growing» idele characters have synthesizable zero sets (§3). We could have expressed the arithmetic pro-
perties for ideles over $\mathbf{Q}$ in a less idelic way, but our procedure produces analogous results in a much more general algebraic number theoretic setting; and we hope that $\hat{\mathrm{J}}_{\mathbf{Q}}$ will serve as a prototype technique to generate some examples in synthesis.

The next problem we pose is that of «analytic continuation ». We move left across $\sigma=1$ and construct pseudomeasures $\mathrm{T}_{s}, 0<\sigma \leqslant 1$, associated with certain $\mathrm{F}(s, x)$ generated from idele characters. The method to construct $\mathrm{T}_{s}$ involves counting solutions to diophantine equations, being careful on the one hand in estimating upper bounds to ensure that $\mathrm{T}_{s}$ is a pseudo-measure, and on the other hand providing specific lower bounds (when this is possible) to guarantee that $\mathrm{T}_{s}$ is not a measure. The spectral synthesis properties of such pseudo-measures are the subject of forthcoming work, but generally the following types of results evolve:
a) $\mathrm{T}_{s}$ generated by «fast growing» idele characters are synthesizable;
b) $\mathrm{T}_{\text {s }}$ generated by «slow growing» idele characters are non-synthesizable;
c) $\varphi_{s}$ generated by "fast growing» idele characters are non-synthesizable.
(The terminology «fast growing», etc. is clarified in § 3.)
Note that with our original non-synthesizable $\varphi_{s}$, the pseudo-measures $\mathrm{T}_{s}$ we obtain in $\sigma \in\left(\frac{1}{2}, 1\right)$ are not only synthesizable but $L^{2}(\mathbf{T})$ functions since $n \longmapsto k_{n}$ is injective for this case.

## Acknospledgement.

I thank W. Adams and R. Holzsager for their ingenious technical assistance which supported my fuzzy intuition on several occasions. Professor Holzsager has made substantial further progress on certain of the arithmetic problems that I have posed here, and he will publish his results separately in a number theoretic format.

## 0. Preliminaries.

### 0.1. Preliminaries from spectral synthesis.

$\mathrm{A}(\mathbf{T})$ is the Banach space of absolutely convergent Fourier series

$$
\varphi(x)=\Sigma a_{n} e^{i n x}
$$

where $\|\varphi\|=\Sigma\left|a_{n}\right|$. The dual of $\mathrm{A}(\mathbf{T})$ is $\mathrm{A}^{\prime}(\mathbf{T})$ the space of pseudo-measures. $\mathrm{A}^{\prime}(\mathbf{T})$ is the subspace of distributions with bounded Fourier coefficients and the canonical dual norm $\left\|\|_{\mathbf{A}^{\prime}}\right.$ on $\mathrm{A}^{\prime}(\mathbf{T})$ is

$$
\|\mathbf{T}\|_{\mathbf{A}^{\prime}}=\sup |\hat{\mathbf{T}}(n)| .
$$

The Radon measures $\mathbf{M}(\mathbf{T})$ are canonically contained in $\mathrm{A}^{\prime}(\mathbf{T})$. If $\mathrm{E} \subseteq \mathbf{T}$ is closed, $\mathrm{A}^{\prime}(\mathrm{E})=\left\{\mathbf{T} \in \mathrm{A}^{\prime}(\mathbf{T})\right.$ : $\left.\operatorname{supp} \mathrm{T} \subseteq \mathrm{E}\right\}$. $\varphi \in \mathrm{A}(\mathbf{T})$ (resp., $T \in \mathrm{~A}^{\prime}(\mathbf{T})$ ) is synthesizable if for all $\mathrm{S} \in \mathrm{A}^{\prime}(\mathrm{Z} \varphi)$ (resp., for all $\psi \in \mathrm{A}(\mathbf{T})$ with $\operatorname{supp} \mathrm{T} \subseteq \mathrm{Z} \psi)\langle\mathrm{S}, \varphi\rangle=0$ (resp., $\langle\mathrm{T}, \psi\rangle=0$ ). E is a synthesis (S) set if for all $\varphi \in \mathrm{A}(\mathbf{T})$ with $\varphi=0 \quad$ on E and for all $\mathrm{T} \in \mathrm{A}^{\prime}(\mathrm{E})$, $\langle\mathrm{T}, \varphi\rangle=0$.

We say that a real-valued $\varphi \in \mathrm{A}(\mathbf{T})$ satisfies condition $\left(\mathrm{M}_{\mathrm{r}}\right)$ if

$$
\begin{array}{lll}
\forall k<r+1 & \exists \mathrm{C}_{\mathrm{K}^{k}}>0 \quad \text { such that } \quad \forall u \in \mathbf{R} \\
& \left\|e^{n \pi+}\right\|_{\mathbf{A}^{\prime}} \leqslant \mathrm{C}_{k}|u|^{-k} .
\end{array}
$$

Clearly $\left(M_{r}\right)$ implies $\left(M_{t}\right)$ if $r \geqslant t$. The following is Malliavin's operational calculus technique and we refer to [2, § B.1] for details, remarks and generalizations.

Proposition 0.1. - If real-salued $\varphi \in A(\mathbf{T})$ satisfies $\left(M_{r}\right)$ for some $r>2$ then $\mathrm{Z} \varphi$ is not an S set.

Remark. - In the proof of the above result we use $\left(\mathrm{M}_{\mathrm{r}}\right)$ to construct $\mathrm{T} \in \mathrm{A}^{\prime}(\mathbf{T})$ such that

$$
\begin{equation*}
\langle\mathrm{T}, \varphi\rangle \neq 0, \quad \mathrm{~T} \varphi^{2}=0 \tag{0.1}
\end{equation*}
$$

Then by an argument which uses Wiener's result on the reciprocal of $\psi \in \mathbf{A}(\mathbf{T})$ we show [1, Theorem $3.15 d$ ] that

S $\theta=0$ implies $\theta=0$ on $\operatorname{supp} S$; thus $\varphi=0$ on $\operatorname{supp} T$ and so $\mathrm{Z} \varphi$ is non-S by (0.1).

We record some routine properties of the \| $\|_{A^{\prime}}$ norm.
(0.2) $\quad \forall \varphi \in \mathbf{A}(\mathbf{T}) \subseteq \mathrm{A}^{\prime}(\mathbf{T}), \quad\|\varphi\|_{\mathbf{A}^{\prime}} \leqslant\|\varphi\|_{\mathbf{A}}$
(0.3) $\forall \varphi \in \mathrm{A}(\mathbf{T}), \quad|\varphi| \leqslant 1, \quad$ either $\quad\|\varphi\|_{\mathbf{A}^{\prime}}<1$
or

$$
(0.4) \xrightarrow{\varphi(x)=a \exp i k x, \quad k \in \mathbf{Z}} \quad \underset{\text { The map }}{\mathbf{A}(\mathbf{T}) \rightarrow \mathbf{R}} \quad \text { and } \quad|a|=1 .
$$

is continuous.
(0.5) $\quad \forall \varphi \in \mathrm{A}(\mathbf{T}), \quad \forall k \in \mathbf{Z} \backslash\{0\}, \quad\|\varphi\|_{\mathbf{A}^{\prime}}=\left\|\varphi^{k}\right\|_{\mathbf{A}^{\prime}}$
where $\varphi^{k}(x)=\varphi(k x)$.

### 0.2. Preliminaries from number theory.

References for the material in this section are [4, Chapters 2 and $15 ; 5 ; 8]$.

For each prime number $p=2,3,5, \ldots$ let $\mathbf{Q}_{p}^{\times}$be the non-zero elements of the $p$-adic completion of $\mathbf{Q}$. Thus

$$
\mathbf{Q}_{p}^{\times}=\left\{\sum_{j=-n}^{\infty} a_{j} p^{j}: 0 \leqslant a_{j}<p, a_{j} \in \mathbf{Z}, \text { some } a_{j} \neq 0, n \geqslant 0\right\}
$$

With the $p$-adic valuation $\left|\left.\right|_{p}, \mathbf{Q}_{p}^{\times}\right.$is a locally compact group under multiplication and is totally disconnected. The compact and open subgroup of units $U_{p}$ for $Q_{p}^{\times}$is

$$
\mathrm{U}_{p}=\left\{\sum_{0}^{\infty} a_{j} p^{j} \in \mathbf{Q}_{P}^{\times}: a_{0} \neq 0\right\}
$$

Let $\mathbf{Q}_{0}^{\times}=\mathbf{R} \backslash\{0\}$. Define $\mathbf{J}_{\mathbf{Q}}$ to be the set of all sequences $\alpha=\left\{\alpha_{p}: p=0,2,3,5, \ldots\right\}$ where $\alpha_{p} \in \mathbf{Q}_{p}^{\times}$and with the property that, for all but a finite number of $p=2,3,5, \ldots$, $\alpha_{p} \in \mathrm{U}_{p}$. Next, consider sets

$$
\mathrm{B}=\prod_{p} \mathrm{~B}_{p} \subseteq \mathrm{~J}_{\mathbf{Q}}
$$

where $\mathrm{B}_{p} \subseteq \mathbf{Q}_{p}^{\times}$is open for all $p=0,2, \ldots$ and $\mathrm{B}_{p}=\mathrm{U}_{p}$ for all but a finite member of $p=2,3, \ldots$. Such sets B form a basis for a topology on $\mathrm{J}_{\mathbf{Q}}$. As such, with component-
wise multiplication, $\mathrm{J}_{\mathbf{Q}}$ is a locally compact abelian group, the idele group corresponding to $\mathbf{Q}$.

It is standard to prove that $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$, the dual group of $\mathbf{J}_{\mathbf{Q}}$, if for each $p=0,2, \ldots$ there is $c_{p} \in \hat{\mathbf{Q}}_{p}^{\times}$such that for all $\alpha=\left\{\alpha_{p}\right\} \in \mathbf{J}_{\mathbf{Q}}$

$$
c(\alpha)=\prod_{p} c_{p}\left(\alpha_{p}\right)
$$

and $c_{p}\left(\mathrm{U}_{p}\right)=1$ for all but a finite number of $p$. When $c_{p}\left(\mathrm{U}_{p}\right)=\{1\}$ we say that $c_{p}$ is unramified.

For each $p=2,3, \ldots$ define $\mathrm{P}_{p} \subseteq \mathbf{Q}_{p}^{\times}$to be

$$
\mathbf{P}_{p}=\left\{\alpha_{p} \in \mathbf{Q}_{p}^{\times}:\left|\alpha_{p}\right|_{p}<1\right\}
$$

and $p_{p}=\mathrm{P}_{p} \cap \mathbf{Z}$. Clearly

$$
\mathbf{P}_{p}=\left\{\sum_{1}^{\infty} a_{j} p^{j} \in \mathbf{Q}_{p}^{\times}\right\}
$$

and so $p_{p}$ is the multiplicative ideal in $\mathbf{Z} \backslash\{0\}$ each of whose elements is divisible by $p$. A neighborhood basis of $1 \in \mathbf{Q}_{p}^{\times} \quad$ in $U_{p}$ is $\left\{1+P_{p}^{n}\right\}$ where $1+P^{0}=U_{p}$. It is standard to check that if $c_{p} \in \hat{\mathbf{Q}}_{P}^{\times}$then there is a smallest integer $n_{p} \geqslant 0$ for which

$$
c_{p}\left(1+\mathrm{P}_{p}^{n_{p}}\right)=\{1\} .
$$

Now, if $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ with corresponding "projections» $c_{p} \in \hat{\mathbf{Q}}_{p}^{\times}$ then there are only finitely many primes $p=2,3, \ldots$ such that the corresponding $n_{p}>0$; this follows since $c_{p}\left(\mathrm{U}_{p}\right)=1$ for all but finitely many $p$. As such, given $c$ we form a multiplicative ideal $f_{c}$ in $\mathbf{Z}$, called the conductor of $c$, defined by

$$
f_{c}=\prod_{n_{p}>0} P_{p}^{n_{p}}
$$

Recall that the fractional ideals in $\mathbf{Q}$ are singly generated. Then, for example, if $p_{1}, \ldots, p_{r}$ are the primes for which $n_{p_{j}}>0, f_{c}$ is generated by $p_{1}^{n_{\rho_{1}}} \ldots p_{r}^{n_{p_{r}}}=h$. We let $\mathrm{G}_{c}$ be the set of multiplicative fractional ideals $\mathrm{A} \subseteq \mathbf{Q}$ generated by $n=q_{1}^{m_{1}} \ldots q_{d}^{m_{d}}, m_{j} \in \mathbf{Z}$, such that each $q_{j}$ is prime and for all $j, k, q_{j} \neq p_{k}$. For $\mathrm{A} \in \mathrm{G}_{c}$ generated by $n$ as
above, we define $\alpha=\left\{\alpha_{p}\right\} \in \mathrm{J}_{Q} \times$ by

$$
\alpha_{p}=\left\{\begin{array}{cc}
1, & p \neq q_{j} \\
q_{j}^{m_{j}}, & p=q_{j}
\end{array}\right.
$$

Then the Hecke character associated with $c$ is a multiplicative homomorphism

$$
\chi_{c}: \mathrm{G}_{c} \rightarrow \mathbf{T}
$$

given by

$$
\chi_{c}(\mathrm{~A})=c_{q_{1}}\left(q_{1}^{m_{1}}\right) \ldots c_{q_{d}}\left(q_{d}^{m_{d}}\right)
$$

The mapping $c \rightarrow \chi_{c}$ is injective.
Observe that we can imbed $\mathbf{Q}^{\times}$into $\hat{\mathbf{J}}_{\mathbf{Q}}$ by the map $q_{1} \rightarrow(q, q, \ldots) . c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ is an idele class character if $c\left(\mathbf{Q}^{\times}\right)=1$. Idele class characters are needed in algebraic number theory to obtain functional equations.

Preserving the above notation between $n$ and A we define the Hecke $L$ series associated with $\chi_{c}$ to be

$$
\mathrm{L}(s, c)=\sum_{(n, h)=1} \frac{\chi_{c}(\mathrm{~A})}{n^{s}}
$$

(for the definition of $L$ we consider only $n \in \mathbf{Z}$, recalling that $n$ could be rational in the definition of $G_{c}$ ). Now, $f_{c}$ is trivial (i.e., $n_{p}=0$ for all $p$ ) if and only if for each $p=2,3, \ldots$

$$
c_{p}\left(\alpha_{p}\right)=\left|\alpha_{p}\right|_{p}^{i t_{p}}
$$

where $t_{p}$ is determined $\bmod 2 \pi / \log p$. Thus for each $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ with trivial conductor there is a unique set of integers $\left\{k_{p}: p=2, \ldots\right\}$ such that

$$
\begin{equation*}
\mathrm{L}(s, c)=\sum_{1}^{\infty} \frac{1}{n^{2}} \exp i \sum_{q} m_{q} k_{q} \tag{0.6}
\end{equation*}
$$

where $n=\Pi q^{m_{q}}$, the prime decomposition of $n$. Conversely given $\left\{k_{p}: p=2, \ldots\right\} \subseteq \mathbf{Z}$ there is a unique $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ defined by

$$
c(n)=\Pi \exp i m_{q} k_{q}
$$

where $\Pi q^{m_{q}}$ is the prime decomposition of $n$.

Finally, if we are given $\left\{k_{p}: p=2, \ldots\right\} \subseteq \mathbf{Z}$ and extend additively by

$$
k_{n}=k_{p}+k_{q} \quad \text { if } \quad n=p q
$$

then (0.6) becomes

$$
\begin{equation*}
\mathrm{L}(s, c)=\sum_{1}^{\infty} \frac{1}{n^{s}} \exp i k_{n} . \tag{0.7}
\end{equation*}
$$

## 1. Pseudo-measure norms and Dirichlet series.

The real part of F defined in (1), considered as a function of $x$ for fixed $s, \sigma>1$, is

$$
\begin{aligned}
\varphi_{s}(x)=\mathrm{F}_{r}(s, x)=\sum_{n=1}^{\infty} \frac{1}{n^{\sigma}}\left[\cos k_{n} x \cos (\tau\right. & \log n) \\
& \left.+\sin k_{n} x \sin (\tau \log n)\right] .
\end{aligned}
$$

Because of condition $\left(\mathrm{M}_{r}\right)$ in $§ 0.1$ we shall consider

$$
\begin{aligned}
\exp i u \varphi_{s}(x)=\prod_{n=1}^{\infty} \exp \frac{i u}{n^{\sigma}}\left[\cos k_{n} x \cos (\tau\right. & \log n) \\
& \left.+\sin k_{n} x \sin (\tau \log n)\right] .
\end{aligned}
$$

As such we define the auxiliary functions

$$
\begin{align*}
\psi_{u, m, s}(x)= & \prod_{n=1}^{m} \exp \frac{i u}{n^{\sigma}}\left[\cos k_{n} x \cos (\tau \log n)\right.  \tag{1.1}\\
& \left.+\sin k_{n} x \sin (\tau \log n)\right]
\end{align*}
$$

and

$$
\begin{align*}
\theta_{u, m, s}(x)=\exp \frac{i u}{(m+1)^{\sigma}}[ & \cos x \cos (\tau \log (m+1))  \tag{1.2}\\
& \left.+\sin x \sin \left(\tau \log _{( }(m+1)\right)\right] .
\end{align*}
$$

Observe that

$$
\psi_{u, m+1, s}=\psi_{a, m, s} \theta_{a, m, s}^{k_{m}^{m+1}} .
$$

Using (0.4) and (0.5) Richards [7, Lemma 1; 2, Theorem B.6] has made the following key observation concerning the growth of $\left\|\|_{A^{\prime}}\right.$.

Proposition 1.1. - Given $\left\{\psi_{u}, \theta_{u}: u \in \mathbf{R}\right\} \subseteq \mathrm{A}(\mathbf{T}) \backslash\{0\}$ and assume $u \longmapsto \psi_{u}, u \longmapsto \theta_{\alpha}$ are continuous functions. Then

$$
\forall \mathrm{R}>0, \quad \forall \varepsilon>0, \quad \exists k \in \mathbf{Z}, \quad k>0,
$$

such that

$$
\begin{gathered}
\forall|u| \leqslant \mathrm{R} \\
\left\|\psi_{u} \theta_{u}^{k}\right\|_{\mathbf{A}^{\prime}}<(1+\varepsilon)\left\|\psi_{u}\right\|_{\mathbf{A}^{\prime}}\left\|\theta_{u}\right\|_{\mathbf{A}^{\prime}} .
\end{gathered}
$$

Fix $\left\{\varepsilon_{k}\right\}$ so that $\varepsilon_{k}>0$ and $\Pi\left(1+\varepsilon_{k}\right) \leqslant 2$. Also for each $c>(1+\sqrt{5}) / 2$ let $B_{c} \subseteq \mathbf{C}$ be the closed rectangle $[1+1 / c, c] \times[-c, c]$. Define an increasing function $c: \mathrm{N} \rightarrow \mathbf{R}, c(m)=\mathrm{R}$, such that

$$
\bigcup_{1}^{\infty} \mathrm{B}_{c}=\{s \in \mathbf{C}: \sigma>1\} .
$$

Using Proposition 1.1 and a uniformity argument we obtain :
Proposition 1.2. - Given $\left\{\varepsilon_{k}\right\}$ and $c$ as above. There is a sequence of integers $k_{n}, n=1,2, \ldots$, increasing to infinity, such that

$$
\forall s \in \mathbf{C}, \quad \sigma>1, \quad \exists \mathrm{~K}_{\sigma}>0
$$

such that

$$
\begin{align*}
\forall m & \geqslant \mathrm{~K}_{\sigma} \quad \forall|u|^{*} \leqslant c(m) \\
\left\|\psi_{a, m+1, s}\right\|_{\mathbf{A}^{\prime}} & <\left(1+\varepsilon_{m}\right)\left\|\psi_{a, m, s}\right\|_{\mathbf{A}^{\prime}}\left\|\theta_{a, m, s}\right\|_{\mathbf{A}^{\prime}} . \tag{1.3}
\end{align*}
$$

Naturally, it may happen that for some $s, \sigma>1$, and some $m$, (1.3) is not true for all $|u| \leqslant c(m)$.

Proposition 1.3.-Given $\left\{\varepsilon_{k}\right\}$ and $c$ as above. Then

$$
\forall s \in \mathbf{C}, \quad \sigma>1, \quad \exists \mathrm{~K}_{\sigma}>0
$$

such that

$$
\begin{gather*}
\forall m \geqslant \mathrm{~K}_{\sigma} \quad \forall|u| \leqslant c(m) \quad \forall n \geqslant m \\
\left\|e^{i u q_{s} \|_{\mathbf{A}^{\prime}}} \leqslant 2 \prod_{j=m}^{n}\right\| \theta_{\mathrm{a}, j, s} \|_{\mathbf{A}^{\prime}} . \tag{1.4}
\end{gather*}
$$

Proof. - Take $\mathrm{K}_{\sigma}$ as in Proposition 1.2 and fix $m \geqslant \mathrm{~K}_{\sigma}$; thus we have (1.3) for all $|u| \leqslant c(m)$.

Arguing iteratively, and using (0.3) and the definition of $\varepsilon_{k}$,

$$
\begin{equation*}
\left\|\psi_{u, k, s}\right\|_{\mathbf{A}^{\prime}} \leqslant 2 \prod_{j=m}^{k}\left\|\theta_{a, j, s}\right\|_{\mathbf{A}^{\prime}} \tag{1.5}
\end{equation*}
$$

for all $k \geqslant m$ and all $|u| \leqslant c(m)$.
(1.4) follows by taking lim's in (1.5) and invoking (0.3) again.

Proposition 1.4. - Given $\left\{\varepsilon_{k}\right\}$ and $c$ as above and form the corresponding F of (1). Take any closed interval $\mathrm{I} \subseteq \mathbf{R} \backslash\{0\}$. Then

$$
\exists \rho \in(0,1)
$$

such that

$$
\begin{align*}
& \forall s \in \mathbf{C}, \quad \sigma>1, \quad \forall n \in \mathbf{Z} \backslash\{0\} \quad \forall u /(m+1)^{\sigma} \in \pm \mathrm{I}, \\
& .6 \theta_{u, m, s}^{n} \|_{\mathbf{A}^{\prime}} \leqslant \rho . \tag{1.6}
\end{align*}
$$

Proof. - From (0.3) and (0.5) there is $\rho_{u, m, s} \in(0,1)$ such that

$$
\forall n \in \mathbf{Z} \backslash\{0\}, \quad\left\|\theta_{a, m, s}^{n}\right\|_{A^{\prime}} \leqslant \rho_{a, m, s} .
$$

For $n$ fixed, the function $\alpha \longmapsto \theta_{a, m, s}^{n}$ from $\mathrm{I} \rightarrow \mathrm{A}(\mathbf{T})$ is continuous, where $\alpha=u /(m+1)^{\sigma}$.
(1.6) follows since continuous functions achieve their maxima on compact sets.
q.e.d.

## 2. Examples of non-S sets.

In light of Proposition 1.3 and Proposition 1.4 we shall see that the key to Theorem 2.1 is to choose $c$ so that for all $n$

$$
\begin{align*}
& \eta^{-1 / \sigma} c(n)^{1 / \sigma}-c(n+1)^{1 / \sigma} \geqslant f(c(n+1))  \tag{2.1}\\
& \eta^{-1 / \sigma} c(n)^{1 / \sigma}-(n+2) \geqslant f(c(n+1))
\end{align*}
$$

for some $\eta \in(0,1)$ and some «relatively quickly increasing» $f$.

Theorem 2.1. - Let $c(n)=e^{n}$ and form the corresponding F of (1). Then for all $s \in \mathbf{C}, \sigma>1$, there is $\mathrm{M}_{\sigma}>0$ and $\delta_{\sigma}>0$ such that

$$
\begin{equation*}
\forall u \in \mathbf{R}, \quad\left\|e^{i u \varphi_{s}}\right\|_{A^{\prime}} \leqslant \mathrm{M}_{\sigma} e^{\left.-\delta_{d} \mid u\right)^{1 / \sigma}} . \tag{2.2}
\end{equation*}
$$

In particular $\left(\mathrm{M}_{r}\right)$ is satisfied for all $r>2$ and $\mathrm{Z} \varphi_{s}$ is non-S.

Proof. - Take $\mathrm{K}_{\tau}$ as in Proposition 1.2 for a fixed $s$. Let $\mathrm{I}=[\eta, 1]$ where $0<\eta<1 / e$.

Choose the corresponding $0<\rho<1$ from Proposition 1.4. Without loss of generality we do the calculation for $u \geqslant 0$.

Take $u \geqslant e^{n_{\sigma}}$ where $n_{\sigma} \geqslant K_{\sigma}$ and $e^{\left(n_{\sigma}+1\right) / \sigma} \geqslant n_{\sigma}+2$; and let $n \geqslant n_{\sigma}$ have the property that

$$
c(n+1) \geqslant u \geqslant c(n) .
$$

From Proposition 1.3

$$
\begin{equation*}
\left\|e^{i a \varphi_{s}}\right\|_{A^{\prime}} \leqslant 2 \prod_{n+1}^{m}\left\|\theta_{u_{i}, j^{\prime}, s}^{k_{j+1}}\right\|_{A^{\prime}} \tag{2.3}
\end{equation*}
$$

for all $|u| \leqslant c(n+1)$ and $m \geqslant n+1$.
For our fixed $u$ and $\sigma$ we now want to count which $j$ 's have the property that

$$
\begin{equation*}
u /(1+j)^{\sigma} \in \mathrm{I} . \tag{2.4}
\end{equation*}
$$

If $c(n+1)^{1 / \sigma} \leqslant 1+j$ then $u /(1+j)^{\sigma} \leqslant 1$ and if

$$
\eta^{1 / \sigma}(1+j) \leqslant c(n)^{1 / \sigma} \quad \text { then } \quad \eta \leqslant u /(1+j)^{\sigma} .
$$

Because of (2.3) and these inequalities the number of $j^{\prime}$ s for which (2.4) holds is estimated by

$$
\begin{equation*}
\eta^{-1 / \sigma} c(n)^{1 / \sigma}-1-\max \left(n+1, c(n+1)^{1 / \sigma}-1\right) \tag{2.5}
\end{equation*}
$$

(note the resemblance to (2.1)).
Since $c(n)=e^{n}$, (2.5) is

$$
\begin{equation*}
e^{n / \sigma}\left(\eta^{-1 / \sigma}-e^{1 / \sigma}\right)=r e^{n / \sigma} \geqslant r e^{-1 / \sigma} u^{1 / \sigma} . \tag{2.6}
\end{equation*}
$$

Combining (2.3), (2.6), and Proposition 1.4 we have (2.2) since $p=e^{-p}, p>0$.
q.e.d.

Remark. - Let us see how much generality we have in choosing $c$ so that Theorem 2.1 is valid. $c(k)$ must grow faster than $k$ so that (2.5) is positive. If $c(k)$ grows like a polynomial the technique of Theorem 2.1 will not work for all $\sigma$ and this leads to the abscissa of convergence problem below. If $c(k)$ grows too fast (e.g., $c(k)=\exp k \log k$ ) the procedure again fails since (2.5) again becomes negative.

Example 2.1. - For the choice of $\left\{k_{n}\right\}$ in Proposition 1.1 and Proposition 1.2 it is desirable to choose the smallest possible $k_{m+1}>0$ given $k_{1}, \ldots, k_{m}>0$. Thus, given $\varepsilon_{1}, c(1)$, and
$k_{1}=1$ we find $k_{2}$. Using Schäfli's integral form for Bessel functions we compute
$\forall N$,

$$
\begin{aligned}
& \sum_{|m|>\mathrm{N}}\left|\hat{\psi}_{u, 1, s}(m)\right|=2 \sum_{m>\mathrm{N}}\left|\mathrm{~J}_{m}(u)\right| \\
& \leqslant 2 \sum_{m>\mathrm{N}}\left|\frac{c(1)}{2}\right|^{m}\left(\sum_{r=0}^{\infty} \frac{c(1)^{2 r}}{2^{2 r} r!(m+r)!}\right) \\
& \leqslant 2 \exp \left(\frac{c(1)^{2}}{4}\right) \sum_{m>\mathrm{N}}\left(\frac{c(1)}{2}\right)^{m} / m!.
\end{aligned}
$$

From the proof of Proposition 1.1 we now take $k_{2}=2 \mathrm{~N}_{\varepsilon_{1}}$ where $\mathrm{N}_{\varepsilon_{1}}$ is the smallest N for which

$$
\sum_{m>\mathrm{N}}\left(\frac{c(1)}{2}\right)^{m} / m!<\frac{\varepsilon_{1}}{2} \exp \left(-\frac{c(1)^{2}}{4}\right) .
$$

Abscissa of Spectral Synthesis Problem. - Given specified F of (1) our calculations [3] indicate that $\mathrm{Z} \varphi_{s}$ becomes more non-spectral as $\sigma \rightarrow 1+$. We would like to determine those F for which there is an abscissa $\sigma=\sigma_{0}$ of spectral synthesis, i.e.,

$$
\begin{array}{ll}
\forall \sigma>\sigma_{0}, & \mathrm{Z} \varphi_{s} \text { is } \mathrm{S} \\
\forall 1<\sigma<\sigma_{0}, & \mathrm{Z} \varphi_{s} \text { is non-S. }
\end{array}
$$

## 3. Spectral synthesis functions and idele characters.

For the remainder of the paper assume for convenience that $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ has trivial conductor, and consider the Hecke L-series characterized by $\left\{k_{p}\right\} \subseteq \mathbf{Z}$, where $p=2,3,5, \ldots$ Given $\mathrm{L}(s, c)$ we associate the Fourier series $\mathrm{F}(s, x)$ (of (1)) for fixed $s, \sigma>1$; and $\mathrm{ZF} \subseteq \mathbf{T}$ is $\{x: \mathrm{F}(s, x)=0\}$, where $s$ is fixed.

Remarks. - 1. If $c$ is an idele class character then the corresponding Hecke character $\chi_{c}$ is precisely a classical Dirichlet character (for Dirichlet L-series); consequently the corresponding Fourier series $\mathrm{F}(s, x)$ is a trigonometric polynomial for each $s, \sigma>1$. In particular $\mathrm{Z} \varphi_{s}$ is finite and thus S .
2. The terminology «fast growing» etc., from the introduction indicates that $\left\{k_{p}\right\}$ tends to infinity at certain rates.

Proposition 3.1. - Given $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ with trivial conductor and corresponding $\left\{k_{p}\right\} \subseteq \mathbf{Z}$.
a) If $k_{p}=0\left(p^{\alpha}\right), p \rightarrow \infty$, for some $\alpha>0$ then

$$
\forall \sigma>1+\alpha, \quad \mathrm{F}(s, x) \in \mathrm{C}^{1}(\mathbf{T}) .
$$

b) If $k_{p}=0(\log p), p \rightarrow \infty$, then

$$
\forall \sigma>1, \quad \mathrm{~F}(s, x) \in \mathrm{C}^{1}(\mathbf{T}) .
$$

c) For each of the above cases, ZF is S .

Proof. - $c$ is clear from the Beurling-Pollard result.
a) Differentiating F with respect to $x$

$$
\left|\sum_{1}^{\infty} \frac{i k_{n}}{n^{n}} e^{i k_{n} x}\right| \leqslant \sum_{1}^{\infty} \frac{\left|k_{n}\right|}{n^{\sigma}}
$$

we need only check that $\left|k_{n}\right| / n^{\alpha}$ is bounded for $\alpha>0$. If $n=\Pi p^{r}$

$$
\left|k_{n}\right| \leqslant \mathrm{K}_{1} \Sigma r p^{\alpha} \leqslant \mathrm{K}_{2} \Sigma p^{\alpha r} \leqslant \mathrm{~K}_{3} n^{\alpha} .
$$

b) Arguing in the same way we need only check that for $\beta>0,\left|k_{n}\right| / n^{\beta}$ is bounded.

If $n=\Pi p^{r}$

$$
\left|k_{n}\right| \leqslant \mathrm{K} \Sigma r \log p=\mathrm{K} \log n
$$

and $\log n / n^{\beta}$ is bounded.

In order to generalize the synthesis result in Proposition 3.1 we say that $\left\{k_{p}\right\} \subseteq \mathbf{Z}^{+}$or the corresponding $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ is $r$-bounded, $r \geqslant 0$, if

$$
\forall \beta>r \quad \exists \mathrm{M}_{\beta} \quad \text { such that } \quad \forall n, \quad k_{n} / n^{\beta} \leqslant \mathrm{M}_{\beta} .
$$

Thus, for example, $k_{p}=\mathrm{O}\left(p^{\alpha}\right), p \rightarrow \infty, \alpha>0$, is 0 -bounded.
Proposition 3.2. - Given $c \in \hat{\mathbf{J}}_{\mathbf{o}}$ with trivial conductor and $\left\{k_{p}\right\} \subseteq \mathbf{Z}^{+}$. If $c$ is r-bounded then for each $\sigma>1+r$, $\mathrm{F}(s, x)$ is a function of bounded variation and ZF is S .

Proof. - The fact that ZF is S if F has bounded variation is standard [6, p. 62]. The bounded variation follows
classically once we observe that

$$
\int_{\mathbf{T}}|\mathrm{F}(s, x+h)-\mathrm{F}(s, x)| d x=\mathrm{O}(h), \quad|h| \rightarrow 0
$$

By direct computation the integral is bounded by $\mathrm{K}|h| \Sigma\left|k_{n}\right| / n^{\sigma} ; \quad$ and so setting $\quad \sigma=1+r+\gamma \quad$ we let $\beta=r+\gamma / 2$ and apply the $r$-boundedness.
q.e.d.

In order to generate non- $\mathrm{S} \mathrm{Z} \varphi$ in $\S 1$ and $\S 2$ the sequence $\left\{k_{n}\right\}$ was chosen to have a certain lacunarity. We now observe that no matter how fast $\overline{\lim }\left|k_{p}\right|$ tends to infinity the sequence $\left\{k_{n}\right\}$, generated by the corresponding $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$, has no lacunarity properties.

Example 3.1. - Given $\boldsymbol{c} \in \hat{\mathbf{J}}_{\mathbf{O}}$ with corresponding $\left\{k_{p}\right\}$. Let $k_{p}>0, k_{p}$ increasing to infinity. If $\left\{k_{m}\right\}$ were lacunary then $k_{m+1} / k_{m} \geqslant \delta>1$ for all $m$. Suppose this is the case. Then for all $m$

$$
\frac{k_{2 m}}{k_{m}}=\frac{k_{2 m}}{k_{2 m-1}} \frac{k_{2 m-1}}{k_{2 m-2}} \cdots \frac{k_{m+1}}{k_{m}}>\delta^{2 m} .
$$

On the other hand

$$
\frac{k_{2 m}}{k_{m}}=1+\frac{k_{2}}{k_{m}}
$$

so that since $k_{p} \rightarrow \infty,\left\{k_{m}\right\}$ can not be lacunary.

## 4. Idelic pseudo-measures.

Given $c \in \hat{\mathbf{J}}_{\mathbf{O}}$ with trivial conductor, and corresponding $\left\{k_{n}\right\} \subseteq \mathbf{Z}$ and F. Our problem is to find conditions in order that

$$
\mathrm{T}_{s} \sim \sum_{n} \frac{1}{n^{s}} e^{i k_{n} x}, \quad 0<\sigma \leqslant 1
$$

represent an element of $\mathrm{A}^{\prime}(\mathbf{T})$ for a fixed $s, 0<\sigma \leqslant 1$; by this we mean that we wish to find conditions on $\left\{k_{p}\right\}$ for which

$$
\begin{equation*}
b_{s}(n)=\sum_{m \in \mathrm{H}(n)} \frac{1}{m^{s}}, \quad \mathrm{H}(n)=\left\{m: k_{m}=n\right\} \tag{4.1}
\end{equation*}
$$

is a bounded sequence. When the sequence $\left\{b_{s}(n): n \in \mathbf{Z}\right\}$ is bounded we say that $c$ determines the pseudo-measure $\mathrm{T}_{s}$.

Clearly Dirichlet characters do not yield pseudo-measures in this way. As a generalization of this fact, we have.

Proposition 4.1. - Given $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ with corresponding $\left\{k_{p}\right\} \subseteq \mathbf{Z}^{+}$. If $\left\{k_{p}\right\}$ is bounded $c$ does not determine a pseudomeasure for any $s, 0<\sigma \leqslant 1$; further, there is $n \geqslant 1$ such that

$$
\sum_{m \in \mathrm{H}(n)} \frac{1}{m}
$$

diverges.
Proof. - Assuming $1 \leqslant k_{p} \leqslant \mathrm{~B}$ we find $n$ such that

$$
\sum_{k_{m}=n} \frac{1}{m}
$$

diverges. Let $C=1 /(B+1)$.
a) We first observe that

$$
\begin{gather*}
\exists n \in[1, \mathrm{~B}] \quad \text { such that } \quad \forall k \geqslant 1, \\
\mathrm{~N}_{j} /(j-k) \geqslant \mathrm{C} \tag{4.2}
\end{gather*}
$$

for infinitely many $j \geqslant k$, where

$$
\mathrm{N}_{j}=\operatorname{card}\left\{k_{p}=n: p_{k} \leqslant p \leqslant p_{j}\right\}
$$

and $p_{j}$ is the $j$-th prime.
$b$ ) Choose $n$ from $a$. Then

$$
\sum_{\substack{m=a \\ p_{m} \in H(n)}}^{j} \frac{1}{p_{m}} \geqslant \sum_{m=j-\mathbf{N}_{j}+1}^{j} \frac{1}{p_{m}} \sim \log p_{j} / p_{j-\mathbf{N}_{j}+1}
$$

by the integral test. Consequently from the prime number theorem

$$
\begin{align*}
& \sum_{\substack{m=a \\
p_{m} \in \mathrm{H}(n)}}^{j} \frac{1}{p_{m}} \geqslant \log \frac{j \log j}{\left(j-\mathrm{N}_{j}+1\right) \log \left(j-\mathrm{N}_{j}+1\right)}  \tag{4.3}\\
& \geqslant \log \frac{j}{j-\mathrm{N}_{j}+1}
\end{align*}
$$

We apply (4.2) which yields $j-\mathrm{N}_{j}+1 \leqslant j(1-\mathrm{C})+1+\mathrm{C} a$
and so the right hand side of (4.3) is greater than or equal to

$$
\log \left(1 /\left[(1-\mathrm{C})+\frac{1}{j}+\mathrm{C} \frac{a}{j}\right]\right)
$$

Now choose $\mathrm{K}, \alpha>0$ such that $\log (1 /[(1-\mathrm{C})+\mathrm{K}])>\alpha$; and then take $j$ large enough so that

$$
(1-\mathrm{C})+\frac{1}{j}+\mathrm{C} \frac{a}{j}<1-\mathrm{C}+\mathrm{K}
$$

Letting $a=a_{i}$ we define $a_{i+1}=j+1$.
Thus starting with $a_{1}=1$ we form $\left\{a_{i}\right\}$ and
$\sum_{m \in \mathbf{H}(n)} \frac{1}{m} \geqslant \sum_{p_{m} \in \mathrm{H}(n)} \frac{1}{p_{m}}=\sum_{i=1}^{\infty} \sum_{\substack{m=a_{i} \\ p_{m} \in \mathrm{H}(n)}}^{a_{i+1}} \frac{1}{p_{m}}>\sum_{1}^{\infty} \alpha=\infty$.
q.e.d.

Proposition 4.2. - Given $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ with corresponding $\left\{k_{p}\right\} \subseteq \mathbf{Z}^{+}$increasing to infinity. Then

$$
\forall n, \quad \operatorname{card} \mathrm{H}(n)<\infty
$$

Proof. - Given $n=\Pi p^{r}$; to show card $\mathrm{H}\left(k_{n}\right)<\infty$. Choose a prime $q=p_{k}$ such that $k_{q}>k_{n}$, by hypothesis.

For each $j<k$ choose $r_{j} \in \mathbf{Z}$ such that $r_{j} k_{p_{j}}>k_{q}$, and define

$$
m_{0}=\prod_{j=1}^{k-1} p_{j}^{r_{j}}
$$

Then

$$
\forall m \geqslant m_{0}, \quad k_{m} \geqslant k_{q}>k_{n}
$$

and so $\mathrm{H}\left(k_{n}\right)$ is finite.
We now give a procedure to find $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ which determine $\mathrm{T}_{s} \in \mathrm{~A}^{\prime}(\mathbf{T}) \backslash \mathbf{M}(\mathbf{T})$.

Lemma. - Let $\mathrm{T} \sim \sum_{1}^{\infty} c_{n} e^{\mathrm{inx}} \in \mathrm{A}^{\prime}(\mathbf{T})$. If

$$
\sum_{1}^{\infty} c_{n} / n \quad \text { diverges }
$$

then $T \in \mathrm{~A}^{\prime}(\mathbf{T}) \backslash \mathrm{M}(\mathbf{T})$.

Proof. - If $\mathrm{T} \in \mathrm{M}(\mathbf{T})$ then

$$
\forall t(x)=\sum_{|n| \leqslant \mathrm{N}} a_{n} e^{i n x}, \quad\left|\sum_{|n| \leqslant \mathrm{N}} a_{n} c_{n}\right| \leqslant\|\mathrm{T}\|_{1}\|t\|_{\infty} .
$$

Take $a_{n} \geqslant 0$ for $n>0,\left\{a_{n}\right\}$ decreasing to 0 , and set $a_{n}=-a_{-n}$ for $n<0$.

Recall, $\left|\sum_{1}^{N} a_{n} \sin n x\right| \leqslant \mathrm{A}(\pi+1)$ if $n a_{n} \leqslant \mathrm{~A}$.
For such $a_{n}$,

$$
\left|\sum_{n=1}^{\mathbb{N}} a_{n} c_{n}\right|=\left|\sum_{|n| \leqslant \mathbb{N}} a_{n} c_{n}\right| \leqslant\|\mathrm{T}\|_{1} 2 \mathrm{~A}(\pi+1)
$$

and so $\sum_{1}^{\infty} a_{n} c_{n}$ converges.
For technical convenience we now let $s=1$.
Proposition 4.3. - Given $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ with corresponding $\left\{k_{p}\right\} \subseteq \mathbf{Z}^{+}$. If

$$
\begin{equation*}
k_{p}=\mathrm{O}\left(\log ^{2} p\right), \quad p \rightarrow \infty \tag{4.4}
\end{equation*}
$$

then $\mathrm{T}_{1} \in \mathrm{~A}^{\prime}(\mathbf{T})$; and $\mathrm{T}_{1} \notin \mathrm{M}(\mathrm{T})$ if

$$
\sum_{1}^{\infty} \hat{\mathrm{T}}_{1}(n) / n
$$

diverges.
Proof. - The fact that $\mathrm{T}_{1} \notin \mathrm{M}(\mathbf{T})$ follows from the Lemma. Assume $\left\{k_{p}\right\}$ increases ot infinity and $k_{p_{1}}>0$.

Let $\Pi(r)$ be the set of all integers

$$
n=\prod_{j=1}^{r} p_{j}^{r_{j}}, \quad r_{j} \geqslant 0 .
$$

We first observe that if

$$
\begin{aligned}
a & =\sum_{1}^{r} 1 / p_{j}, \\
b & =\sum_{m \in \Pi(r)} 1 / m,
\end{aligned}
$$

then

$$
\begin{equation*}
e^{a}-1<b<e^{2 a}-1 . \tag{4.5}
\end{equation*}
$$

This follows since

$$
1+b=\prod_{j=1}^{r}\left(1+\frac{1}{p_{j}}+\frac{1}{p_{j}^{2}}+\cdots\right)
$$

and

$$
e^{1 / p}<1+\frac{1}{p}+\frac{1}{p^{2}}+\cdots=1+\frac{1}{p-1} \leqslant 1+\frac{2}{p}<e^{2 / p}
$$

Set

$$
\mathrm{H}_{n, r}=\sum_{m \in \mathbf{H}(n) \cap \Pi(r)} \frac{1}{m}
$$

We use (4.4), (4.5), and Mertens' estimate

$$
\sum_{p \leqslant x} \frac{1}{p}=\log \log x+\mathrm{C}+\mathrm{O}(1 / \log x), \quad x \rightarrow \infty
$$

to calculate

$$
\begin{aligned}
& \text { (4.6) } \mathrm{H}_{n, r} \leqslant \sum_{m \in \mathbb{\Pi}(r)} 1 / m \leqslant \exp 2 \sum_{1}^{r} 1 / p_{j} \\
& \leqslant \mathrm{C}\left(\log p_{r}\right)^{2} \leqslant \frac{\mathrm{~K}}{2} k_{p_{r}}<\mathrm{K} k_{p_{r}}\left(1-\frac{1}{p_{r+1}-1}\right), \quad \mathrm{K} \geqslant 1,
\end{aligned}
$$

for all $n$.
Note that

$$
\Pi(r+1)=\Pi(r) \cup p_{r+1} \Pi(r) \cup p_{r+1}^{2} \Pi(r) \cup \cdots,
$$

a disjoint union. Thus,

$$
\mathrm{H}(n) \cap \Pi(r+1)=\bigcup_{j=0}^{\infty}\left(\mathrm{H}(n) \cap p_{r+1}^{j} \Pi(r)\right)
$$

is a disjoint union.
If $m \in \mathrm{H}(n) \cap \Pi(r+1)$ then $k_{m}=n$ and $m=u p_{r+1}^{j}$, $u \in \Pi\left(\mathrm{~S}_{\mathrm{r}}\right)$. Thus

$$
k_{u}=n-j k, \quad k=k_{p_{r+1}} .
$$

Consequently,

$$
\sum_{m \in \mathbf{H}(n) \cap p_{r+1}^{j} \Pi(r)} 1 / m=\sum_{\substack{u \in \mathbf{H}\left(n-j_{k}\right) \\ u \in(r)}} 1 /\left(u p_{r+1}^{j}\right)=\frac{1}{p_{r+1}^{j}} \mathbf{H}_{n-j k, r}
$$

and so
(4.7) $\quad \mathrm{H}_{n, r+1}=\mathrm{H}_{n, r}+\frac{1}{p_{r+1}} \mathrm{H}_{n-k, r}+\frac{1}{p_{r+1}^{2}} \mathrm{H}_{n-2 k, r}+\cdots$.

From (4.5) there is $M \geqslant 1$ such that

$$
\forall n, \quad \mathrm{H}_{n, 1} \leqslant \mathrm{M} .
$$

Since $b_{1}(n)=\sup _{r} H_{n, r}$ we'll prove that if $n$ is fixed then

$$
\mathrm{H}_{n, r} \leqslant \mathrm{MK} k_{p_{4}} \quad \text { for each } r .
$$

Using (4.6) and (4.7),

$$
\begin{aligned}
& \mathrm{H}_{n, 2} \leqslant \\
& \quad \mathrm{H}_{n, 1}+\mathrm{M}\left(\frac{1}{p_{2}-1}\right) \\
& \quad \leqslant \operatorname{MK} k_{p_{4}}\left(1-\frac{1}{p_{2}-1}\right)+\mathrm{MK} k_{p_{4}}\left(\frac{1}{p_{2}-1}\right)=\mathrm{MK} k_{p_{4}} .
\end{aligned}
$$

We argue similarly for any $H_{n, r}$.
q.e.d.

Example 4.1. - Condition (4.4) determines many pseudomeasures. We note that $k_{p}=[\log p]$ also determines a pseudomeasure by appropriate technical refinements. In order to give specific examples of $\mathbf{T} \in \mathrm{A}^{\prime}(\mathbf{T}) \backslash \mathbf{M}(\mathbf{T})$ determined by $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ we now use $k_{p}=[\log p], k_{2}=1$ (for technical convenience only). If $n$ is given and $k \leqslant n$ then from the prime number theorem ( $p_{j} \sim j \log j, j \rightarrow \infty$ ) the number of primes in $\left[e^{k}, e^{k+1}\right)$ is estimated by $e^{k}(k(e-1)-1) / k(k+1) \equiv \mathrm{N}_{k}$. Thus there are approximately $\mathrm{N}_{k}$ primes $p$ for which $k_{p}=k$. Therefore we write

$$
\begin{array}{rcc} 
& n & m\left(\text { where } k_{m}=n\right) \\
\bar{n} & =1+1+\cdots+1 & m \\
=1 \\
=k_{3}+1+\cdots+1 & & =3 \cdot 2^{n-k_{3}}  \tag{4.8-2}\\
= & \vdots & \\
=k_{p(n)} & & =p(n)
\end{array}
$$

where $p(n)$ is the largest prime $p$ for which $k_{p}=n$. Consequently the sum $\Sigma \frac{1}{m}$ for those $m$ listed in (4.8) is bounded below approximately by

$$
\begin{equation*}
\frac{1}{e} \sum_{\substack{k+a=n+1 \\ a \geqslant 0 \\ k \geqslant 2}} \frac{1}{2^{a}} \frac{(k-1)(e-1)-1}{(k-1) k} \tag{4.9-2}
\end{equation*}
$$

We rewrite (4.9) as

$$
\frac{1}{e} \sum_{a=0}^{n-1} \frac{1}{2^{a}} \frac{(n-a)(e-1)-1}{(n-a)(n+1-a)}
$$

and estimate it by
(4.10-2) $\frac{1}{n}+\frac{1}{2(n-1)}+\frac{1}{2^{2}(n-2)}+\cdots+\frac{1}{2^{n-1}}$
(we can also estimate the integral

$$
\left.e^{-n} \int_{1}^{n} \frac{e^{x}}{x} d x\right)
$$

For the next steps we form (4.8-3), ..., (4.8-p), ... where if $m$ is listed in (4.8-p) and $k_{m}=n$ then

$$
m=q 2^{a_{a} 3^{a_{3}}} \ldots p^{a_{p}}
$$

where $q$ is a prime or 1 and if $a_{2}+\cdots+a_{p-1}>0$ then $a_{p}>0$. We form the corresponding sum (4.9-p) by again counting the number of primes $q$ in the allowable (that is, $a_{p}>0$ and $n=k_{q}+a_{2} k_{2}+\cdots+a_{p} k_{p}$ ) intervals ( $\left.e^{k}, e^{k+1}\right)$. Consequently, we form a sequence of finite sums (4.10-p) whose total sum over $p$ is a lower bound $b(n)$ of $\hat{\mathrm{T}}_{\mathbf{1}}(n)$ and check that $\sum_{1} b(n) / n$ diverges.

Example 4.2. - If $\mathrm{E} \subseteq \mathbf{Z}$ is lacunary (e.g., Example 3.1) then E is Sidon [6]. Sidon sets are a special case of $\Lambda(t)$ sets for all $t \in(0, \infty) . \mathrm{V}(t)$ sets E , for $t \in(1, \infty)$, are characterized by the property that

$$
\{\mu \in \mathbf{M}(\mathbf{T}): \forall n \notin \mathrm{E}, \hat{\mu}(n)=0\} \subseteq \mathrm{L}^{t}(\mathbf{T}) .
$$

Given $c \in \hat{\mathbf{J}}_{\mathbf{Q}}$ with corresponding $k_{p}$ (let $\left\{k_{p}\right\}$ increase to infinity with $\left.k_{2} \geqslant 1\right) . r_{t}\left(n,\left\{k_{p}\right\}\right)$ is the number of representations of $n$ as a sum of $t$ elements, possibly repeated, from $\left\{k_{p}\right\}$. When $\left\{k_{p}\right\}$ is not $\Lambda(2 t)$ for any $t$ then

$$
\forall t, \quad \sup _{n} r_{t}\left(n,\left\{k_{p}\right\}\right)=\infty .
$$

Consequently, such $c \in \hat{\mathrm{~J}}_{\mathbf{Q}}$ which further satisfy (4.4) are a natural source in which to find $T \in A^{\prime}(\mathbf{T}) \backslash M(\mathbf{T})$.
