# On the asymptotic equidistribution of sums of independent identically distributed random variables 

by<br>W. STADJE<br>Mathematik/Informatik, Universität Osnabrück, 45 Osnabrück, Postfach 44 69, West Germany

Abstract. - For a sum $S_{n}$ of $n$ I.I.D. random variables the idea of approximate equidistribution is made precise by introducing a notion of asymptotic translation invariance. The distribution of $S_{n}$ is shown to be asymptotically translation invariant in this sense iff $S_{1}$ is nonlattice. Some ramifications of this result are given.

Key words : Sums of I.I.D. random variables, asymptotic equidistribution, asymptotic translation invariance.

Résumé. - On introduit, pour une somme $\mathrm{S}_{n}$ de $n$ variables aléatoires indépendantes équidistribuées, une notion d'invariance asymptotique par translation, qui permet de rendre précise l'idée d'équidistribution approximative. On montre que la loi de $S_{n}$ est asymptotiquement invariante par translation en ce sens si, et seulement si, la loi de $\mathrm{S}_{1}$ est non arithmétique. On donne quelques extensions de ce résultat.

## 1. INTRODUCTION

Let $T_{1}, T_{2}, \ldots$ be a sequence of independent random variables with a common distribution $\mathrm{P}^{\mathrm{T}_{n}}=\mathrm{P}^{\mathrm{T}_{1}}$ and let $\mathrm{S}_{n}=\mathrm{T}_{1}+\ldots+\mathrm{T}_{n}$. Intuitively, if
$E\left(T_{1}\right)=0$ and $T_{1} \not \equiv 0$, the mass of the probability measure $P^{S_{n}}$ is expected to be approximately "equidistributed", as $n$ becomes large. If $\mathrm{E}\left(\mathrm{T}_{1}\right)>0$, one is inclined to think of something like an "approach to uniformity at infinity". An old result of this kind is due to Robbins (1953). If $T_{1}$ is not concentrated on a lattice,

$$
\begin{equation*}
n^{-1} \sum_{i=1}^{n} h\left(\mathrm{~S}_{i}\right) \rightarrow \lim _{\mathrm{T} \rightarrow \infty}(2 \mathrm{~T})^{-1} \int_{-\mathrm{T}}^{\mathrm{T}} h(x) d x, \quad \text { as } \quad n \rightarrow \infty \tag{1.1}
\end{equation*}
$$

for all almost periodic functions $h$ (i.e. if $h$ is the uniform limit of trigonometric polynomials). For a partial sharpening of this result see Theorem 3 of Stadje (1985). In the case when $T_{1}$ is not concentrated on a lattice, $\mathrm{E}\left(\mathrm{T}_{1}\right)=0$ and $0<\sigma^{2}:=\operatorname{Var}\left(\mathrm{T}_{1}\right)<\infty$, the expectation of asymptotic equidistribution can also be justified by the limiting relation

$$
\begin{equation*}
\sigma(2 \pi n)^{1 / 2} \mathrm{P}\left(\mathrm{~S}_{n} \in \mathrm{I}\right) \rightarrow \lambda(\mathrm{I}), \quad \text { as } \quad n \rightarrow \infty \tag{1.2}
\end{equation*}
$$

which is valid for all bounded intervals $\mathrm{I} \subset \mathbb{R}$, where $\lambda$ denotes the Lebesgue measure (Shepp (1964), Stone (1965, 1967), Breiman (1968), chapt. 10).

One might try to interpret approximate uniformity of $\mathrm{P}^{\mathbf{S}_{n}}$ by stating that $P\left(S_{n} \in I\right)$ asymptotically only depends on the length of $I$. Since $\lim \mathrm{P}\left(\mathrm{S}_{n} \in \mathrm{I}\right)=0$ for every bounded interval I , this idea should be made $n \rightarrow \infty$
reasonable by examining the speed of convergence of $\mathrm{P}\left(\mathrm{S}_{n} \in \mathrm{I}\right)$. This is done in (1.2) stating $a_{n} \mathrm{P}^{\mathrm{S}_{n}}$ approaches the Lebesgue measure, where $a_{n}=\sigma(2 \pi n)^{1 / 2}$.

In this paper another approach to the idea of equidistribution of $\mathrm{P}^{S_{n}}$ is developed. The essential property of an "equidistribution" is the invariance under translations. To measure the degree of translation invariance of a probability measure Q on $\mathbb{R}$, we introduce, for $a \in \mathbb{R}$ and $t>s>0$, the quantities

$$
\begin{gather*}
d(a, t, \mathrm{Q}):=\sum_{i=-\infty}^{\infty}|\mathrm{Q}((a+i t, a+(i+1) t])-\mathrm{Q}((a+(i-1) t, a+i t])|  \tag{1.3}\\
\mathrm{D}(t, \mathrm{Q}):=\sup _{a \in \mathbb{R}} d(a, t, \mathrm{Q})  \tag{1.4}\\
\tilde{\mathrm{D}}(s, t, \mathrm{Q}):=\sup _{s \leqq u \leqq t} \mathrm{D}(u, \mathrm{Q}) . \tag{1.5}
\end{gather*}
$$

We call a sequence $\left(\mathrm{Q}_{n}\right)_{n \geqq 1}$ of probability measures asymptotically translation invariant (ATI), if $\lim _{n \rightarrow \infty} \tilde{\mathrm{D}}\left(s, t, \mathrm{Q}_{n}\right)=0$ for all $t>s>0$. The main theorem of this paper states that $\left(\mathrm{P}^{\mathrm{S}_{n}}\right)_{n \geqq 1}$ is ATI if, and only if, $\mathrm{P}^{\mathrm{T}_{1}}$ is not concentrated on a lattice. No moment conditions are needed for this equivalence. Let $\mathrm{D}_{n}(t):=\tilde{\mathrm{D}}\left(t^{-1}, t, \mathrm{P}_{n}\right), t>1$. Regarding the speed of convergence of $\mathrm{D}_{n}(t)$ we remark that

$$
\begin{equation*}
\liminf _{n \rightarrow \infty} n^{1 / 2} \mathrm{D}_{n}(t)>0 \quad \text { for all } t>1, \quad \text { if } \quad \mathrm{E}\left(\mathrm{~T}_{1}^{2}\right)<\infty \tag{1.6}
\end{equation*}
$$

To see (1.6), let without loss of generality $\mathrm{E}\left(\mathrm{T}_{1}\right)=0$ and $\mathrm{E}\left(\mathrm{T}_{1}^{2}\right)=1$. Then, by Chebyshev's inequality,

$$
\begin{equation*}
\mathrm{P}\left(\left|\mathrm{~S}_{n}\right|<n^{1 / 2}\right) \geqq 1-n^{-1} . \tag{1.7}
\end{equation*}
$$

The interval ( $-n^{1 / 2}, n^{1 / 2}$ ) can be covered by $\left[2 n^{1 / 2} / t\right]+1$ half-open intervals of length $t$. One of these intervals, say I, obviously satisfies

$$
\begin{equation*}
\mathrm{P}\left(\mathrm{~S}_{n} \in \mathrm{I}\right) \geqq\left(1-n^{-1}\right) /\left(\left[2 n^{1 / 2} / t\right]+1\right) \geqq \frac{1}{2} \frac{1}{2 n^{1 / 2} t+1}, \quad \text { if } \quad n \geqq 2 \tag{1.8}
\end{equation*}
$$

Choose $a \in[0, t]$ and $i_{0} \in \mathbb{Z}$ such that $\mathrm{I}=\left(a+i_{0} t, a+\left(i_{0}+1\right) t\right]$.
Then

$$
\begin{align*}
& d\left(a, t, \mathrm{P}^{\mathrm{S}_{n}}\right) \geqq \sum_{i=-\infty}^{i_{0}}\left[\mathrm{P}\left(\mathrm{~S}_{n} \in(a+i t, a+(i+1) t]\right)\right. \\
&\left.\quad \quad-\mathrm{P}\left(\mathrm{~S}_{n} \in(a+(i-1) t, a+i t]\right)\right]
\end{aligned} \quad \begin{aligned}
& \quad=\mathrm{P}\left(\mathrm{~S}_{n} \in\left(a+i_{0} t, a+\left(i_{0}+1\right) t\right]\right) \geqq \frac{1}{4 t+2} n^{-1 / 2}, \quad n \geqq 2 \tag{1.9}
\end{align*}
$$

(1.6) follows from (1.9).

In order to derive a converse result to (1.6), we need a further notion. A distribution $Q$ on $\mathbb{R}$ is called strongly nonlattice, if its characteristic function $\varphi$ satisfies

$$
\begin{equation*}
\limsup _{|\zeta| \rightarrow \infty}|\varphi(\zeta)|<1 . \tag{1.10}
\end{equation*}
$$

The second main result of this note is that if $\mathrm{P}^{\mathrm{T}_{1}}$ is strongly nonlattice,

$$
\begin{equation*}
\limsup _{n \rightarrow \infty} n^{1 / 2} \mathrm{D}_{n}(t)<\infty \quad \text { for all } t>1 \tag{1.11}
\end{equation*}
$$

## 2. THE MAIN THEOREM

We shall prove
Theorem 1. - The following two statements are equivalent.
(a) $\mathrm{P}^{\mathrm{T}_{1}}$ is nonlattice.
(b) $\left(\mathrm{P}^{\mathrm{S}_{n}}\right)_{n \geqq 1}$ is ATI.

Proof. $-(a) \Rightarrow(b)$. Assume first that $\mathrm{E}\left|\mathrm{T}_{1}\right|^{3}<\infty$ and $\mathrm{E}\left(\mathrm{T}_{1}\right)=0$. Let $\sigma^{2}=\mathrm{E}\left(\mathrm{T}_{1}^{2}\right), \mu_{3}=\mathrm{E}\left(\mathrm{T}_{1}^{3}\right)$ and denote the distribution function of $\mathrm{S}_{n}$ by $\mathrm{F}_{n}$. Then

$$
\begin{align*}
d\left(a, t, \mathrm{P}^{\mathrm{S}_{n}}\right)=\sum_{i=-\infty}^{\infty} \mid \mathrm{F}_{n}(a+(i+1) t)-2 \mathrm{~F}_{n}(a+i t) & \\
& +\mathrm{F}_{n}(a+(i-1) t) \mid \tag{2.1}
\end{align*}
$$

Since $\mathrm{P}^{\mathrm{T}_{1}}$ is nonlattice, a well-known expansion for distribution functions yields

$$
\begin{equation*}
\mathrm{F}_{n}\left(n^{1 / 2} \sigma x\right)=\Phi(x)+\frac{\mu_{3}}{6 \sigma^{3} n^{1 / 2}}\left(1-x^{2}\right) \varphi(x)+\varepsilon_{n}(x) n^{-1 / 2} \tag{2.2}
\end{equation*}
$$

for all $x \in \mathbb{R}$, where

$$
\begin{equation*}
\varepsilon_{n}:=\sup _{x \in \mathbb{R}}\left|\varepsilon_{n}(x)\right| \rightarrow 0, \quad \text { as } \quad n \rightarrow \infty \tag{2.3}
\end{equation*}
$$

and $\Phi$ and $\varphi$ are the distribution function and density of $N(0,1)$ (see e.g. Feller (1971), p. 539). It is easy to check that for each $j \in \mathbb{N}$ and $a \in[0, t]$

$$
\begin{align*}
& \sum_{i>j}\left|\mathrm{~F}_{n}(a+(i+1) t)-2 \mathrm{~F}_{n}(a+i t)+\mathrm{F}_{n}(a+(i-1) t)\right| \\
& \leqq 1-\mathrm{F}_{n}(a+(j+1) t)+1-\mathrm{F}_{n}(a+j t) \leqq 2 \mathrm{P}\left(\mathrm{~S}_{n}>j t\right) \tag{2.4}
\end{align*}
$$

and

$$
\begin{align*}
& \sum_{i<-j}\left|\mathrm{~F}_{n}(a+(i+1) t)-2 \mathrm{~F}_{n}(a+i t)+\mathrm{F}_{n}(a+(i-1) t)\right| \\
& \leqq \leqq \mathrm{F}_{n}(a-j t)+\mathrm{F}_{n}(a-(j+1) t) \leqq 2 \mathrm{P}\left(\mathrm{~S}_{n} \leqq-(j-1) t\right) \tag{2.5}
\end{align*}
$$

Inserting (2.2)-(2.5) into (2.1) we obtain, for $a \in[0, t]$,

$$
\begin{array}{rl}
d\left(a, t, \mathrm{P}^{\mathrm{S}}\right) \leqq 2 & \mathrm{P}\left(\left|\mathrm{~S}_{n}\right| \geqq(j-1) t\right)+(2 j+1) \varepsilon_{n} n^{-1 / 2} \\
+\sum_{i=-\infty}^{\infty}\left|\Phi\left(\frac{a+(i+1) t}{\sigma n^{1 / 2}}\right)-2 \Phi\left(\frac{a+i t}{\sigma n^{1 / 2}}\right)+\Phi\left(\frac{a+(i-1) t}{\sigma n^{1 / 2}}\right)\right| \\
& \left.+\frac{\left|\mu_{3}\right|}{6 \sigma^{3} n^{1 / 2}} \sum_{i=-\infty}^{\infty} \right\rvert\,\left(1-x_{i+1}^{2}\right) \varphi\left(x_{i+1}\right) \\
& -2\left(1-x_{i}^{2}\right) \varphi\left(x_{i}\right)+\left(1-x_{i-1}^{2}\right) \varphi\left(x_{i-1}\right) \mid \tag{2.6}
\end{array}
$$

where $x_{i}:=(a+i t) / \sigma n^{1 / 2}$. By Chebyshev's inequality,

$$
\begin{equation*}
2 \mathrm{P}\left(\left|\mathrm{~S}_{n}\right| \geqq(j-1) t\right)+(2 j+1) \varepsilon_{n} n^{-1 / 2} \leqq \frac{2 \sigma^{2} n}{t^{2}(j-1)^{2}}+(2 j+1) \varepsilon_{n} n^{-1 / 2} \tag{2.7}
\end{equation*}
$$

The smallest order of magnitude of the righthand side of (2.7) is attained for $j=j_{n}$ being equal to the integer part of $n^{1 / 2} \varepsilon_{n}^{-1 / 3}$; in this case

$$
\begin{align*}
2 \mathrm{P}\left(\left|\mathrm{~S}_{n}\right| \geqq\left(j_{n}-1\right) t\right)+\left(2 j_{n}+1\right) \varepsilon_{n} & n^{-1 / 2} \\
& =\left(1+t^{-2}\right) O\left(\varepsilon_{n}^{2 / 3}\right), \quad \text { as } \quad n \rightarrow \infty \tag{2.8}
\end{align*}
$$

Next we estimate the two series in (2.6). Let $X$ be a standard normal random variable. Then the first sum at the righthand side of (2.6) is equal
to

$$
\begin{align*}
& \sum_{i=-\infty}^{\infty} \mid \mathrm{P}\left(\sigma n^{1 / 2} \mathrm{X} \in\right.(a+i t, a+(i+1) t]) \\
& \quad-\mathrm{P}\left(\sigma n^{1 / 2} \mathrm{X}-t \in(a+i t, a+(i+1) t)\right] \mid \\
& \leqq\left(\sigma n^{1 / 2}\right)^{-1} \int_{-\infty}^{\infty}\left|\varphi\left(x / \sigma n^{1 / 2}\right)-\varphi\left((x+t) / \sigma n^{1 / 2}\right)\right| d x \\
&=2\left(\sigma^{1 / 2}\right)^{-1}[ {\left[\int_{-\infty}^{-t / 2} \varphi\left((x+t) / \sigma n^{1 / 2}\right) d x-\int_{-\infty}^{-t / 2} \varphi\left(x / \sigma n^{1 / 2}\right) d x\right] } \\
&= 2 \int_{-t / 2 \sigma n^{1 / 2}}^{t / 2 \sigma n^{1 / 2}} \varphi(u) d u=t O\left(n^{-1 / 2}\right), \quad \text { as } n \rightarrow \infty . \tag{2.9}
\end{align*}
$$

To estimate the last sum at the right side of (2.6), note that the function $\left(1-x^{2}\right) \exp \left(-x^{2} / 2\right)$ has four points of inflexion. Regarding the sequence

$$
a_{i}:=\left(1-x_{i+1}^{2}\right) \varphi\left(x_{i+1}\right)-\left(1-x_{i}^{2}\right) \varphi\left(x_{i}\right), \quad i \in \mathbb{Z}
$$

this implies that $\left(a_{i}-a_{i-1}\right)_{i \in \mathbb{Z}}$ changes signs at most four times. Using its telescoping form the sum in question can be bounded from above as follows:

$$
\begin{equation*}
\sum_{i=-\infty}^{\infty}\left|a_{i}-a_{i-1}\right| \leqq 8 \sup _{-\infty<i<\infty}\left|a_{i}\right| \tag{2.10}
\end{equation*}
$$

Further, by the mean value theorem,

$$
\begin{equation*}
\left|a_{i}\right| \leqq\left|x_{i+1}-x_{i}\right| \sup _{x \in \mathbb{R}}\left|\frac{d}{d x}\left(1-x^{2}\right) \varphi(x)\right|=\mathrm{K} t / \sigma n^{1 / 2} \tag{2.11}
\end{equation*}
$$

for some constant K. Inserting (2.8)-(2.11) into (2.6) we arrive at

$$
\begin{equation*}
d\left(a, t, \mathrm{P}_{n}\right)=\left(1+t^{-2}\right) O\left(\varepsilon_{n}^{2 / 3}\right)+t O\left(n^{-1 / 2}\right), \quad \text { as } \quad n \rightarrow \infty \tag{2.12}
\end{equation*}
$$

so that

$$
\begin{equation*}
\mathrm{D}\left(t, \mathrm{P}_{n}\right)=\left(1+t^{-2}\right) O\left(\varepsilon_{n}^{2 / 3}\right)+t O\left(n^{-1 / 2}\right), \quad \text { as } \quad n \rightarrow \infty . \tag{2.13}
\end{equation*}
$$

To establish the assertion without moment conditions we first remark that $\mathrm{D}(t, \mathrm{Q})$ is translation invariant in the sense that

$$
\begin{equation*}
\mathrm{D}(t, \mathrm{Q})=\mathrm{D}\left(t, \mathrm{Q} * \varepsilon_{x}\right) \quad \text { for all } x \in \mathbb{R}, \quad t>0 \tag{2.14}
\end{equation*}
$$

where $*$ denotes convolution and $\varepsilon_{x}$ is the point mass at $x$. Thus, (2.13) holds, if $\mathrm{E}\left|\mathrm{T}_{1}\right|^{3}<\infty$ (without the assumption $\mathrm{E}\left(\mathrm{T}_{1}\right)=0$ ). Further, for probability measures Q and R we have

$$
\begin{equation*}
\mathrm{D}(t, \mathrm{Q} * \mathrm{R}) \leqq \mathrm{D}(t, \mathrm{Q}) \tag{2.15}
\end{equation*}
$$

(2.15) is proved as follows:

$$
\begin{align*}
& \mathrm{D}(t, \mathrm{Q} * \mathrm{R})= \sup _{a} \sum_{i=-\infty}^{\infty} \mid(\mathrm{Q} * \mathrm{R})((a+i t, a+(i+1) t]) \\
&-(\mathrm{Q} * \mathrm{R})((a+(i-1) t, a+i t]) \mid \\
& \leqq \sup _{a} \sum_{i=-\infty}^{\infty} \int_{-\infty}^{\infty} \mid \mathrm{Q}((a+i t-x, a+(i+1) t-x]) \\
&\quad-\mathrm{Q}((a+(i-1) t-x, a+i t-x)]) \mid d \mathrm{R}(x) \\
& \leqq \int_{-\infty}^{\infty} \sup _{a} \sum_{i=-\infty}^{\infty} \mid \mathrm{Q}((a+i t-x, a+(i+1) t-x]) \\
& \quad \mathrm{Q}((a+(i-1) t-x, a+i t-x]) \mid d \mathrm{R}(x) \\
&=\int_{-\infty}^{\infty} \mathrm{D}(t, \mathrm{Q}) d \mathrm{R}(x)=\mathrm{D}(t, \mathrm{Q}) . \tag{2.16}
\end{align*}
$$

Next suppose that $P^{\mathbf{T}_{1}}=\alpha Q+(1-\alpha) R$ for some $\alpha \in(0,1]$ and probability measures $Q$ and $R$ such that $Q$ satisfies, for some constants $K_{1}, K_{2}$,

$$
\begin{equation*}
\mathrm{D}\left(t, \mathrm{Q}^{* n}\right) \leqq\left(1+t^{-2}\right) \mathrm{K}_{1} \varepsilon_{n}^{2 / 3}+t \mathrm{~K}_{2} n^{-1 / 2}, \quad \text { as } \quad n \rightarrow \infty \tag{2.17}
\end{equation*}
$$

( $\mathrm{Q}^{* n}$ is the $n$-fold convolution of Q with itself). Then

$$
\begin{array}{r}
\mathrm{D}\left(t, \mathrm{P}_{n}\right)=\sup _{a} \sum_{i=-\infty}^{\infty} \left\lvert\, \sum_{l=0}^{n}\binom{n}{l} \alpha^{l}(l-\alpha)^{n-l}\left\{\mathrm{Q}^{* l} * \mathrm{R}^{*(n-l)}((a+i t,\right.\right. \\
\left.a+(i+1) t])-\mathrm{Q}^{* l} * \mathrm{R}^{*(n-l)}((a+(i-1) t, a+i t])\right\} \mid \\
\leqq \sum_{l=0}^{n}\binom{n}{l} \alpha^{l}(1-\alpha)^{n-l} \mathrm{D}\left(t, \mathrm{Q}^{* l} * \mathrm{R}^{*(n-l)}\right) \\ \tag{2.18}
\end{array}
$$

Let $\delta_{n}:=\sup _{l>n} \varepsilon_{l}$. Then $\delta_{n} \downarrow 0$ and, by Chebyshev's inequality for the binomal distribution and (2.17), it follows that, for arbitrary $\varepsilon \in(0, \alpha)$,

$$
\begin{align*}
& \sum_{l=0}^{n}\binom{n}{l} \alpha^{l}(1-\alpha)^{n-l} \mathrm{D}\left(t, \mathrm{Q}^{* l}\right) \leqq 2 \sum_{l \leqq(\alpha-\varepsilon) n}\binom{n}{l} \alpha^{l}(1-\alpha)^{n-l} \\
& +\left(1+t^{-2}\right) \mathrm{K}_{1} \sup _{l>(\alpha-\varepsilon) n} \varepsilon_{l}+t \mathrm{~K}_{2}((\alpha-\varepsilon) n)^{-1 / 2} \\
& \leqq 2 \alpha(1-\alpha) \varepsilon^{-2} n^{-1}+\mathrm{K}\left[\left(1+t^{-2}\right) \delta_{(\alpha-\varepsilon) n}+t n^{-1 / 2}\right] \tag{2.19}
\end{align*}
$$

where $K=\max \left(K_{1}, K_{2}\right)$. (2.19) implies that $\mathrm{D}_{n}(t) \rightarrow 0$, as $n \rightarrow \infty$, for all $t>1$.

Now we choose a function $f$ on $\mathbb{R}$ such that $0<f(x)<1$ for all $x \in \mathbb{R}$ and

$$
\int_{-\infty}^{\infty}|x|^{3} f(x) d \mathrm{P}^{\mathrm{T}_{1}}(x)<\infty
$$

Let $\alpha:=\int_{-\infty}^{\infty} f(x) d \mathrm{P}^{\mathrm{T}_{1}}(x)$ and define the probability measures Q and R by $d \mathrm{Q}:=\alpha^{-1} f d \mathrm{P}^{\mathrm{T}_{1}}, d \mathrm{R}=(1-\alpha)^{-1}(1-f) d \mathrm{P}^{\mathrm{T}_{1}}$. Then the third moment of $Q$ is finite and $Q$ is nonlattice so that $Q$ satisfies (2.17). Since $\mathrm{P}^{\mathrm{T}_{1}}=\alpha \mathrm{Q}+(1-\alpha) \mathrm{R}$, it follows that $\mathrm{D}_{n}(t) \rightarrow 0$.
$(b) \Rightarrow(a)$. Let $\mathrm{P}^{\mathbf{T}_{1}}$ have span $\lambda>0$. If $t \in(0, \lambda / 2)$, at most one of the successive intervals $(a+(i-1) t, a+i t]$ and $(a+i t, a+(i+1) t]$ contains a multiple of $\lambda$. Therefore it is obvious that $d\left(a, t, \mathrm{P}^{\mathrm{S}_{n}}\right)=2$ for all $a \in \mathbb{R}$, $t \in(0, \lambda / 2)$ and $n \in \mathbb{N}$.

## 3. THE STRONGLY NONLATTICE CASE

Concerning the speed of convergence of $\mathrm{D}_{n}(t)$ we shall now prove
Theorem 2. - If $\mathrm{P}^{\mathrm{T}_{1}}$ is strongly nonlattice,

$$
\begin{equation*}
\lim \sup n^{1 / 2} \mathrm{D}_{n}(t)<\infty \quad \text { for all } t>1 \tag{3.1}
\end{equation*}
$$

Proof. - Let $\eta:=\limsup _{|\zeta| \rightarrow \infty}|\varphi(\zeta)|<1$. We can decompose $\mathrm{P}^{\mathrm{T}_{1}}=\alpha \mathrm{Q}+(1-\alpha) \mathrm{R}$, where $\alpha \in(0,1]$ and Q and R are probability measures such that $Q$ is strongly nonlattice and concentrated on a bounded interval. If $\mathrm{P}^{\mathrm{T}_{1}}$ itself is concentrated on a bounded interval, this is trivial. Otherwise let $\alpha_{N}:=P\left(T_{1} \in[-N, N]\right)$, where $N$ is large enough to ensure $0<\alpha_{N}<1$. Define, for Borel sets B,

$$
\begin{gathered}
\mathrm{Q}_{\mathrm{N}}(\mathrm{~B}):=\alpha_{N}^{-1} \mathrm{P}\left(\mathrm{~T}_{1} \in \mathrm{~B} \cap[-\mathrm{N}, \mathrm{~N}]\right) \\
\mathrm{R}_{\mathrm{N}}(\mathrm{~B}):=\left(1-\alpha_{\mathrm{N}}\right)^{-1} \mathrm{P}\left(\mathrm{~T}_{1} \in \mathrm{~B} \backslash[-\mathrm{N}, \mathrm{~N}]\right) .
\end{gathered}
$$

Then the characteristic functions $\tilde{\varphi}_{N}$ and $\tilde{\underline{\varphi}}_{N}$ of $Q_{N}$ and $R_{N}$ satisfy $\tilde{\varphi}_{N}=\alpha_{N}^{-1}\left(\varphi-\left(1-\alpha_{N}\right) \widetilde{\tilde{\varphi}}_{\mathrm{N}}\right)$ so that

$$
\begin{equation*}
\limsup _{|\zeta| \rightarrow \infty}\left|\tilde{\varphi}_{N}(\zeta)\right| \leqq \alpha_{N}^{-1}\left(\eta+1-\alpha_{N}\right) \tag{3.2}
\end{equation*}
$$

and the righthand side of (3.2) is smaller than 1 for sufficiently large N , because $\alpha_{N} \uparrow 1$.

We proceed by proving the assertion for Q instead of $\mathrm{P}^{\mathrm{T}_{1}}$. Obviously we may assume that $\int x d \mathrm{Q}(x)=0$. Let $\mathrm{F}_{n}$ be the distribution function of
$\mathrm{Q}^{* n}$ and $\sigma^{2}:=\int x^{2} d \mathrm{Q}(x)$. Since Q is strongly nonlattice and possesses moments of all orders, a well-known expansion yields, for every $r \geqq 3$,

$$
\begin{equation*}
\mathrm{F}_{n}\left(n^{1 / 2} \sigma x\right)-\Phi(x)-\varphi(x) \sum_{k=3}^{r} n^{-(k / 2)+1} \mathrm{R}_{k}(x)=o\left(n^{-(r / 2)+1}\right) \tag{3.3}
\end{equation*}
$$

uniformly in $x$, where $\mathrm{R}_{k}$ is a polynomial depending only on the first $r$ moments of Q(see, e. g., Feller (1971), p. 541). Letting $r=5$ and proceeding as in (2.4)-(2.6) we obtain, for arbitrary $j$,
$d\left(a, t, \mathrm{Q}^{* n}\right) \leqq 2 \mathrm{Q}^{* n}(\mathbb{R} \backslash[-(j-1) t,(j-1) t])$

$$
\begin{gather*}
+(2 j+1) o\left(n^{-3 / 2}\right)+\sum_{i=-j}^{j} \left\lvert\, \Phi\left(\frac{a+(i+1) t}{\sigma n^{1 / 2}}\right)\right. \\
\left.-2 \Phi\left(\frac{a+i t}{\sigma n^{1 / 2}}\right)+\Phi\left(\frac{a+(i-1) t}{\sigma n^{1 / 2}}\right) \right\rvert\, \\
+\sum_{k=3}^{5} n^{-(k / 2)+1} \sum_{i=-j}^{j} \mid \varphi\left(x_{i+1}\right) \mathrm{R}_{k}\left(x_{i+1}\right)-2 \varphi\left(x_{i}\right) \mathrm{R}_{k}\left(x_{i}\right) \\
+\varphi\left(x_{i-1}\right) \mathrm{R}_{k}\left(x_{i-1}\right) \mid . \tag{3.4}
\end{gather*}
$$

Here again $x_{i}=(a+i t) / \sigma n^{1 / 2}$. Since each function $\varphi(x) \mathrm{R}_{k}(x)$ has a bounded derivative and only a finity number of points of inflexion, the same reasoning as in the proof of Theorem 1 (for $\mathrm{R}(x)=1-x^{2}$ ) shows that, for $k=3,4,5$,

$$
\begin{align*}
& \sum_{i=-\infty}^{\infty} \mid \varphi\left(x_{i+1}\right) \mathrm{R}_{k}\left(x_{i+1}\right)-\varphi\left(x_{i}\right) \mathrm{R}_{k}\left(x_{i}\right) \\
& \quad \begin{array}{l}
\quad-\left[\varphi\left(x_{i}\right) \mathrm{R}_{k}\left(x_{i}\right)-\varphi\left(x_{i-1}\right) \mathrm{R}_{k}\left(x_{i-1}\right)\right] \mid \\
\leqq \mathrm{L} \sup _{-\infty<i<\infty}\left|\varphi\left(x_{i+1}\right) \mathrm{R}_{k}\left(x_{i+1}\right)-\varphi\left(x_{i}\right) \mathrm{R}_{k}\left(x_{i}\right)\right| \\
\leqq \tilde{\mathrm{L}} \sup _{-\infty<i<\infty}\left|x_{i+1}-x_{i}\right|=\tilde{\mathrm{L}} t / \sigma n^{1 / 2}
\end{array}
\end{align*}
$$

where L and $\tilde{\mathrm{L}}$ are appropriate constants. Thus the last term at the right side of (3.4) is $t O\left(n^{-1 / 2}\right)$. Further using (2.9) for the remaining sum in (3.4) and Chebyshev's inequality we arrive at

$$
\begin{align*}
d\left(a, t, \mathrm{Q}^{* n}\right) \leqq 2 \mathrm{Q}^{* n}(\mathbb{R} \backslash & {[-(j-1) t,(j-1) t]) } \\
& +(2 j+1) o\left(n^{-3 / 2}\right)+t O\left(n^{-1 / 2}\right) \\
& =t^{-2} O\left(n / j^{2}\right)+(2 j+1) o\left(n^{-3 / 2}\right)+t O\left(n^{-1 / 2}\right) \tag{3.6}
\end{align*}
$$

Choosing $j=j_{n}=n^{5 / 6}$, (3.6) implies that

$$
\begin{equation*}
d\left(a, t, \mathrm{Q}^{* n}\right)=t^{-2} O\left(n^{-2 / 3}\right)+t O\left(n^{-1 / 2}\right) \tag{3.7}
\end{equation*}
$$

Now arguing similarly as in (2.18) and (2.19),
$\mathrm{D}\left(t, \mathrm{P}_{n}\right) \leqq \sum_{l=0}^{n}\binom{n}{l} a^{l}(1-\alpha)^{n-l} \mathrm{D}\left(t, \mathrm{Q}^{* l}\right)$

$$
\begin{equation*}
\leqq 2 \alpha(1-\alpha) \varepsilon^{-2} n^{-1}+\mathrm{K}\left[t^{-2} O\left(n^{-2 / 3}\right)+t O\left(n^{-1 / 2}\right)\right] \tag{3.8}
\end{equation*}
$$

where $\varepsilon>0$ and K are constants. It follows that $\mathrm{D}_{n}(t)=O\left(n^{-1 / 2}\right)$ for each $t>1$, as claimed.
