# GEVREY HYPOELLIPTICITY FOR A CLASS OF OPERATORS 

WITH MULTIPLE CHARACTERISTICS .
by L. RODINO (Università di Torino)

INTRODUCTION.

In this paper we prove a result of Gevrey regularity for a certain class of quasi-elliptic operators degenerate on a symplectic manifold; representative examples in $\mathbb{R}_{x, y}^{2}$ are given by

$$
\begin{equation*}
P=D_{x}-r_{1} x_{D_{y}}^{k} \tag{0.1}
\end{equation*}
$$

$$
\begin{equation*}
P=\left(D_{x}-r_{1} x^{h} D_{y}^{k}\right)\left(D_{x}-r_{2} x^{h} D_{y}^{k}\right)+\lambda x^{h-1} D_{y}^{k}, \tag{0.2}
\end{equation*}
$$

where $h, k$ are fixed positive integers and $\operatorname{Im} r_{j} \neq 0$ for $j=1,2$, say $\operatorname{Im} r_{1}<0$ and $\operatorname{Im} r_{2}>0$.

The hypoellipticity of a related class of pseudo differential operators was discussed in Parenti-Rodino [8]; in particular, for $P$ in (0.1) we have hypoellipticity if and only if one at least of the integers $h, k$ is even, whereas $p$ in (0.2) is hypoelliptic if and only if the parameter $\lambda \in \mathbb{C}$ avoids a certain discrete set of eigenvalues. The nature of the arguments in [8] was microlocal, and this allowed several geometric invariant applications (see Part II in [8]). Here, arguing from a local point of view, we shall limit ourselves to the case of a "flat" symplectic characteristic manifold and we shall consider only linear partial differential operators; in this situation we shall be able to prove a result of Gevrey regularity by combining some a priori estimates in [8] and a method of

## L. RODINO

Grushin, Section 5 of [4]. For $P$ in (0.1), (0.2) it will come out that hypoellipticity implies Gevrey hypoellipticity with respect to suitable classes. Let us note that the above-mentioned argument of Grushin, which we generalize here in a trivial way, can be microlocalized, as we hope to show in future papers, so that it applies actually also to the pseudo differential case, for example to the operators which we obtain in (0.1), (0.2) by fixing $k=1$ and allowing $r_{1}, r_{2}$, $\lambda$ to be analytic pseudo differential operators of order zero (for operators of similar type the analytic hypoellipticity has been proved recently by Trèves [12], Tartakoff [11], Métivier [7], by means of other methods and under the additional assumption $h=1$ ).

## 1. STATEMENT OF THE RESULT.

Let us first recall some definitions concerning Gevrey classes and quasielliptic operators. Write $z$ for the real variable in $\mathbb{R}^{n}$ and let $M=\left(M_{1}, \ldots, M_{n}\right)$ be a fixed $n$-tuple of positive rational numbers. Let $\Omega$ be an open subset of $\mathbb{R}^{n}$. We define $G^{M}(\Omega)$ to be the class of all $f \in C^{\infty}(\Omega)$ such that for every $\mathrm{KCC} \Omega$

$$
\begin{equation*}
\max _{z \in K}\left|D_{z}^{\mu} f(z)\right| \leq C_{K}^{|\mu|+1}\left(\mu_{1}!\right)^{M_{1}} \ldots\left(\mu_{n}!\right)^{M_{n}} \tag{1.1}
\end{equation*}
$$

for all $\mu=\left(\mu_{1}, \ldots, \mu_{n}\right) \in z_{+}^{n}$ and with a constant $C_{K}$ depending only on $f$ and $K$. When $M_{j}=1$ for every $j, j=1, \ldots, n, G^{M}(\Omega)$ consists of all analytic functions in $\Omega$. The $G^{M}$-singular support of a distribution $f \in \mathscr{D}^{( }(\Omega)$, $G^{M}$ - sing supp $f$, is defined in this way: $x_{0} \notin G^{M}$-sing supp $f$ if and only if there exists a neighborhood $V C \Omega$ of $x_{0}$ such that $f \in G^{M}(V)$. We say that a linear partial differential operator $P$ with coefficients in $G^{M}(\Omega)$ is $G^{M}$-hypoelliptic in $\Omega$ if

$$
\begin{equation*}
G^{M} \text { - sing supp } P f=G^{M} \text {-sing supp } f, \text { for every } f \in \mathscr{D}^{\prime}(\Omega) \tag{1.2}
\end{equation*}
$$

Typical examples of $G^{M}$-hypoelliptic operators are the $M$-quasi-elliptic operators, i.e. the linear partial differential operators $P=\sum_{\langle\mu, M>\leq m} c_{\mu}(z) D_{z}^{\mu}$, $c_{\mu} \in G^{M}(\Omega)$, such that in $\Omega \sum_{<\mu, M>=m} c_{\mu}(z) \zeta^{\mu} \neq 0$ for $\zeta \neq 0$ (Volevich [13]; for the constant coefficients see Hörmander [5], Chapter 4, and Pini [9]; see also Zanghirati [14], where the classes $G^{M}(\Omega)$ are characterized through the iterations of such operators).

We shall consider here a class of operators $P$ quasi-elliptic with respect to a suitable weight $M$, which degenerate on a flat symplectic submanifold of $\Omega \times \mathbb{R}_{\zeta}^{n} . \operatorname{Fix} \nu, 1 \leq \nu<n$, and split $z=(x, y), \quad x=\left(x_{1}=z_{1}, \ldots, x_{\nu}=z_{\nu}\right) \in \mathbb{R}^{\nu}$, $y=\left(y_{1}=z_{\nu+1}, \ldots, y_{n-\nu}=z_{n}\right) \in R^{n-\nu}$. Let $L=\left(L_{1}, \ldots, L_{n-\nu}\right)$ be a given ( $\left.n-\nu\right)$-tuple of positive integers with $\min L_{j}=1$ and let $k$ be a given common multiple of the $L_{j}$ 's. Fix finally two positive integers $h$ and $m_{1}$, and write $m=m_{1} k$. We define

$$
\begin{equation*}
P=\sum_{(\alpha, \beta, \gamma) \in \gamma \not \subset}{ }^{a}{ }_{\alpha \beta \gamma}(z) x^{\gamma} D_{x}^{\alpha} D_{y}^{\beta}, \tag{1.3}
\end{equation*}
$$

where the set of indices $X X C \subset \mathbf{z}_{+}^{\nu} \times \mathbf{z}_{+}^{n-\nu} \times \mathbf{z}_{+}^{\nu}$ is given by

$$
\begin{align*}
& X \gamma C=\{(\alpha, \beta, \gamma) ;|\alpha| k+\langle\beta, L>\leq m, h m \geq| \gamma|k \geq|\alpha| k+(1+h)<\beta, L>-m  \tag{1.4}\\
& \text { and } \left.\beta_{j} L_{j} / k \in \mathbf{z}_{+} \text {for all } j=1, \ldots, n-\nu\right\} .
\end{align*}
$$

Consider the $n$-tuple

$$
\begin{equation*}
M=\left(M_{1}, \ldots, M_{n}\right), M_{j}=k \text { for } 1 \leq j \leq \nu, M_{j}=L_{j-\nu} \text { for } v+1 \leq j \leq n, \tag{1.5}
\end{equation*}
$$

and suppose the coefficients $a_{\alpha \beta \gamma}$ are in $G^{M}(\Omega)$, where now $\Omega$ is in a neighborhood of the origin in $\mathbb{R}^{n}$. Introduce also the sets of indices

$$
\begin{align*}
& W \mathcal{C}_{0}=\{(\alpha, \beta, \gamma) \in M(,|\gamma| k=|\alpha| k+(1+h)<\beta, L>-m\},  \tag{1.6}\\
& \mathscr{X} \mathcal{C}_{0}=\left\{(\alpha, \beta, \gamma) \in \mathcal{X} \mathcal{C}_{0},|\alpha| k+\langle\beta, L\rangle=m\right\} . \tag{1.7}
\end{align*}
$$

Writing $\zeta, \xi, \eta$ for the dual variables of $z, x, y$, respectively, we assume

Since $\langle\mu, M\rangle=|\alpha| k+\langle\beta, L\rangle$ with our choice of $M$ and with $\mu=(\alpha, \beta)$, condition
(1.8) implies the (micro) M-quasi-ellipticity of $P$ outside the manifold
$\{x=0, \xi=0\}$, for $z$ in a small neighborhood of the origin in $\mathbb{R}^{n}$; then in view of Volevich [13] $P$ is $G^{M}$-hypoelliptic for $x \neq 0$.

Consider now the operator with polynomial coefficients in $\mathbb{R}_{\mathbf{x}}^{V}$

$$
\begin{equation*}
\mathscr{O}\left(\eta, x, D_{x}\right)=\sum_{(\alpha, \beta, \gamma) \in \gamma \gamma l_{0} a_{\alpha \beta \gamma}(0) \eta^{\beta} x_{D_{x}}^{\alpha}} \tag{1.9}
\end{equation*}
$$

and assume

$$
\begin{equation*}
\operatorname{Ker}^{\mathscr{C}}\left(\eta, x, D_{x}\right) \cap \mathscr{P}\left(\mathbb{R}_{x}^{\nu}\right)=\{0\} \text { for all } \eta \neq 0 \tag{1.10}
\end{equation*}
$$

Condition (1.10), joined with (1.8), guarantees the hypoellipticity of $P$ in $a$ full neighborhood of the origin (see Parenti-Rodino [8]), and it is also necessary for the hypoellipticity when the coefficients $a_{\alpha \beta \gamma}$ are constant (see Taniguchi [10]). In the case $V=1$ it is possible to translate (1.10) into explicit conditions on the coefficients $a_{\alpha \beta \gamma}$ (Mascarello-Rodino [6], Sections 3, 4, 5). The result which we shall prove here is the following:

Theorem 1.1: Under the preceding hypotheses, and in particular under the conditions (1.8), (1.10) and the assumption $a_{\alpha \beta \gamma} \in G^{M}(\Omega), M$ as in (1.5), the operator $P$ in (1.3) is $G^{M}$-hypoelliptic in a neighborhood of the origin. For example the models of the Introduction are $G^{(k, 1)}$-hypoelliptic, for any $h$, if and only if they are hypoelliptic. When $k=1, L_{j}=1$ for every $j$, we
recapture the result of Grushin [4]. In the case $m=2, k=1$ or $k=2$, Theorem 1.1 intersects also some well known results about the analytic and Gevrey regularity of the second order operators (see Baouendi-Goulaouic [1], Derridj-Zuily [2], Durand [3] for a general study in this connection).

## 2. PROOF .

Applying the result of Volevich [13] in the region where $x \neq 0$ and observing that assumptions (1.8), (1.10) are invariant for small translations in the $y$ variables, we are reduced to prove the following statement: if $f \in \mathscr{D}^{\prime}$ (v) and Pf $\in G^{M}(V)$, for $M$ as in (1.5) and for some neighborhood $V$ of the origin in $\mathbb{R}^{n}, \bar{V} C \subset \Omega$, then $f$ is in $G^{M}\left(V^{\prime}\right)$, for some other neighborhood $V^{\prime} C V$. Actually, since we know from the results of [8] that $P$ is hypoelliptic at the origin it will be not restrictive to argue under the additional assumption $f \in C^{\infty}(V)$.

We shall use the following estimate for $L^{2}$-norms: if the hypotheses of Theorem 1.1 are satisfied, there exists a neighborhood $U$ of the origin in $\mathbb{R}^{n}$ and a constant $C>0$ such that

$$
\begin{equation*}
\sum_{(\alpha, \beta, \gamma) \in X \not \subset C}\left\|x^{\gamma} D_{x}^{\alpha} D_{y}^{\beta} u\right\| \leq c\|P u\| \text { for every } \quad u \in C_{o}^{\infty}(U) \tag{2.1}
\end{equation*}
$$

This inequality follows easily from the properties of continuity of the parametrix of $P$ in [8] (see in particular the proof of Theorem 3.1 in the first part of the paper). Let us write for $\rho>0$

$$
\begin{equation*}
B_{\rho}=\left\{z=(x, y) \in \mathbb{R}^{n},|x|<\rho^{k} \text { and } \sum_{j=1}^{n-v}\left|y_{j}\right|^{2 / L_{j}}<\rho^{2}\right\} . \tag{2.2}
\end{equation*}
$$

By passing to a new system of coordinates we can assume without loss of generality

## L. RODINO

$U=B_{2}$ in (2.1) and, at the same time, $f \in C^{\infty}(V)$, $P f \in G^{M}(V)$ for a neighborhood $V$ of $B_{2}$. We shall prove that $f$ is then in $G^{M}\left(B_{1}\right)$. Let us begin with two technical lemmas.

Lemma 2.1: Let $\rho, \rho_{1}$ be given positive constants and let $M$ be the weight in (1.5). There exists $\phi \in C_{0}^{\infty}\left(\mathbb{R}^{n}\right)$ such that supp $\phi \subset B_{\rho_{1}+\rho}, \phi(z)=1$ for $z \in{ }^{B} \rho_{1}, 0 \leq \phi(z) \leq 1$ for every $z \in \mathbb{R}^{n}$ and
(2.3) $\quad \max \left|D_{z}^{\mu} f(z)\right| \leq c_{\mu} \rho^{-<\mu, M>}$
where $c_{\mu}$ does not depend on $\rho, \rho_{1}$; moreover $D_{x}^{\alpha} \phi(z)=0$ for $|x|<\rho_{1}^{k}$ if $|\alpha| \neq 0$.

Lemma 2.2: Let $f$ be in $C^{\infty}(V)$ and fix $K C C V$. The following conditions are equivalent:

There exists $A>0$ such that for all $\mu \in \mathbb{Z}_{+}^{n}$ $\max _{z \in K} \mid D_{z}^{\mu_{f}(z) \mid \leq A^{|\mu|+1}\left(\mu_{1}!\right)^{M_{1}} \ldots\left(\mu_{n}!\right)^{M_{n}} .}$.

There exists $A>0$ such that for all $\mu \in \mathbf{z}_{+}^{n}$
$\max _{z \in K}\left|D_{z}^{\mu} f(z)\right| \leq A(A<\mu, M>)^{<\mu, M>} \quad$.

For every integer $t \geq 0$ write $I_{t}=\left\{\mu \in \mathbb{Z}_{+}^{\mathrm{n}},\langle\mu, \mathrm{M}\rangle \leq \mathrm{t}\right\}$; there exists $A>0$ such that for all $t \geq 0$
$\max _{\mu \in I_{t}} \max _{z \in K}\left|D_{z}^{\mu} f(z)\right| \leq A^{t+1} t!\quad$.
Let $\left(J_{t}\right)$ be a sequence of finite subsets of $z_{+}^{n}$ such that $I_{t-t_{1}} \subset J_{t} \subset I_{t+t_{2}}$, for suitable fixed integers $t_{1}, t_{2} \geq 0$ and for every $t \geq t_{1}$. There exists $A>0$ such that for all $t \geq 0$
$\max _{\mu \in J_{t}} \max _{z \in K}\left|D_{z}^{\mu_{f(z)}}\right| \leq A^{t+1} t!\quad$.

$$
\begin{align*}
& \text { For }\left(J_{t}\right) \text { as in }(2.7) \text {, there exists } A>0 \text { such that for all } t \geq 0  \tag{2.8}\\
& \max \|_{\mu \in J_{t}}^{\mu_{f} \|_{L^{2}(K)} \leq A^{t+1} t!}
\end{align*}
$$

The construction of $\phi$ in Lemma 2.1 is standard (cf. Lemma 1.6 in [14], for example). As for Lemma 2.2, one gets easily from Stirling's formula that $(2.4) \longleftrightarrow(2.5)$ and $(2.5) \longleftrightarrow(2.6)$; the equivalence $(2.6) \longleftrightarrow(2.7)$ is obvious and $(2.7) \longleftrightarrow(2.8)$ is a consequence of the embedding theorems of Sobolef (the statement is valid in this case for any $n$-tuple $M$ of rational positive numbers). In the sequel we shall apply Lemma 2.2 with $M$ as in (1.5) and with the following choice of the sets $J_{t}$ :
(2.9)

$$
\left\{\begin{array}{l}
J_{t}=J_{t}^{1} \cup J_{t}^{2} \\
J_{t}^{1}=\{\mu=(\alpha, \beta), 2|\alpha| k+\langle\beta, L\rangle \leq t \quad \text { and }|\alpha| k \leq(1+h) m\} \\
J_{t}^{2}=\left\{\mu=(\alpha, \beta), \mu \in I_{t-(1+h) m} \text { and }|\alpha| k \geq(1+h) m\right\}
\end{array}\right.
$$

since now $I_{t}=\{\mu=(\alpha, \beta),|\alpha| k+\langle\beta, L\rangle \leq t\}$ we have $I_{t-(1+h) m} \subset J_{t} \subset I_{t}$ for $t \geq(1+h) m$ and the assumption on $J_{t}$ in (2.7) is satisfied. Using Lemma 2.2 with $K=B_{2}$ and $J_{t}$ as in (2.9), we obtain from the hypotheses $P f \in G^{M}(V)$, $a_{\alpha \beta \gamma} \in G^{M}(V)$ that for a suitable constant $A$ and for all $t \geq 0$

$$
\begin{equation*}
\max _{\mu \in J_{t}}\left\|D_{z}^{\mu} P f\right\|_{L^{2}\left(B_{2}\right)} \leq A^{t+1} t! \tag{2.10}
\end{equation*}
$$

$$
\begin{equation*}
\max _{\mu \in I_{t}} \max _{z \in B_{2}}\left|D_{z}^{\mu} a_{\alpha \beta \gamma}(z)\right| \leq A^{t+1} t! \tag{2.11}
\end{equation*}
$$

Set now for $f \in C^{\infty}(V)$ and $1 \leq \sigma \leq 2$

$$
\begin{align*}
& \|\|f, \sigma\|\|=\sum_{(\alpha, \beta, \gamma) \in \partial d l}\left\|x^{\gamma} D_{x}^{\alpha_{y}} D_{D^{\beta}}\right\|_{L^{2}\left(B_{\sigma}\right)},  \tag{2.12}\\
& \|f f, \sigma\|\left\|_{t}=\max _{\mu \in J_{t}}\right\| D_{z}^{\mu} f, \sigma\| \| . \tag{2.13}
\end{align*}
$$

Take $\rho>0$ and $\rho_{1}>1$, with $\rho_{1}+\rho<2$, and let $\phi$ be defined according to Lemma 2.1. From the estimate (2.1) we obtain for any $\mu \in \mathbb{Z}_{+}^{n}$
(2.14) $\quad\left\|D_{z}^{\mu_{f}, \rho_{1}}\right\| \leq\|\mid\| D_{z}^{\mu_{f}, 2}\| \| \leq c\left\|P\left(\phi D_{z}^{\mu}\right)\right\|$.

Then writing

$$
\begin{equation*}
\left\|P\left(\phi D_{z}^{\mu} f\right)\right\| \leq\left\|\phi D_{z}^{\mu}{ }_{P f}\right\|+\left\|[P, \phi]_{z}^{\mu} f\right\|+\left\|\phi\left[P, D_{z}^{\mu}\right]_{f}\right\| \tag{2.15}
\end{equation*}
$$

we have for every $t \geq 0$

$$
\begin{equation*}
\left\|f, \rho_{1}\right\| \|_{t} \leq c \max _{\mu \in J_{t}}\left\{\left\|D_{z}^{\mu} P_{L f}\right\|_{\left(B_{2}\right)}+\left\|[P, \phi]_{z}^{\mu} f\right\|+\left\|\left[P, D_{z}^{\mu}\right]_{f}\right\|_{L^{2}{ }_{\left(B_{\rho_{1}+\rho}\right)}}\right\} \tag{2.16}
\end{equation*}
$$

The two last terms in the right-hand side of (2.16) will be estimated by means of the following lemmas; in the statements $t_{o}$ represents a large integer, which will be determined in the proofs.

Lemma 2.3. For every $\mu \in J_{t}, t \geq t_{0}$, we have

$$
\begin{equation*}
\left\|[P, \phi] D_{z}^{\mu} f\right\| \leq c \sum_{j=1}^{m} \rho^{-j}\| \| f, \rho_{1}+\rho\| \|_{t-j} \tag{2.17}
\end{equation*}
$$

where the constant $C$ does not depend on $\rho, \rho_{1}, t$.
Lemma 2.4. There exists $C>0$ such that for every $\mu \in J_{t}, t \geq t_{0}$ :

$$
\begin{equation*}
\left\|\left[P, D_{z}^{\mu}\right]_{f}\right\|_{L^{2}\left(B_{\rho_{1}+\rho}\right)} \leq c \sum_{j=1}^{t} A^{j} \frac{t!}{(t-j)!} \|\left.\right|_{f, \rho_{1}+\rho \mid \|_{t-j}} \tag{2.18}
\end{equation*}
$$

Applying the lemmas and the hypothesis (2.10), from (2.16) we deduce the inequality

$$
\begin{align*}
&\left\|\|f, \rho,\|_{t} \leq c\{ \right. A^{t+1} t!  \tag{2.19}\\
&+\sum_{j=1}^{m} \rho^{-j}\left\|f, \rho_{1}+\rho \mid\right\| \|_{t-j} \\
&\left.+\sum_{j=1}^{t} A^{j} \frac{t!}{(t-j)!}\left\|f, \rho_{1}+\rho\right\| \|_{t-j}\right\}
\end{align*}
$$

where the constant $C$ does not depend on $\rho, \rho_{1}, t$ and we assume $t \geq t_{o}$. Let now $s$ be any fixed integer, $s \geq t_{0}$, and define for $t \leq s-t_{0}$ :

$$
\begin{equation*}
\omega_{s, t}=s^{-t-t_{0}}\|\mid f, 2-(t+1) / s\| \|_{t} \tag{2.20}
\end{equation*}
$$

If we set $\rho=1 / s, \rho_{1}=2-t / s$, from (2.19) we obtain for a new constant $c_{1}$ :

$$
\begin{equation*}
\omega_{s, t} \leq C_{1}\left\{A^{t}+\sum_{j=1}^{m} \omega_{s, t-j}+\sum_{j=1}^{t} A^{j} \omega_{s, t-j}\right\} \tag{2.21}
\end{equation*}
$$

It is now easy to prove that there exists a constant $B$ independent of $s$ and t, $\mathrm{B}>1$, such that

$$
\begin{equation*}
\omega_{s, t} \leq(2 B)^{t+1} \text { for } t \leq s-t_{0} \tag{2.22}
\end{equation*}
$$

In fact, (2.22) is trivially satisfied by a suitable $B$ if $t \leq t_{o}$, and it can be proved to be valid in general for a large $B$ arguing by induction and using (2.21) (cf. [4], Section 5). In particular, if we set in (2.22) $t=s-t_{0}$ we obtain that for some constant $c_{2}$ and for $s \geq t_{0}$

$$
\begin{equation*}
\left\|\left\|, 2-\left(s-t_{0}+1\right) / s\right\|_{s-t_{0}} \leq\left(C_{2} s\right)^{s}\right. \tag{2.23}
\end{equation*}
$$

From (2.23), from Lemma 2.2, from Stirling's formula and from the obvious estimates

$$
\begin{equation*}
\max _{\mu \in J_{t}}\left\|D_{z}^{\mu_{f} \|_{L\left(B_{1}\right)}^{2}} \underset{t}{ } \leq\right\| f, 1\| \|_{t} \tag{2.24}
\end{equation*}
$$

## L. RODINO

we get finally the conclusion $f \in G^{M}\left(B_{1}\right)$.
It remains to prove Lemma 2.3 and Lemma 2.4. Of course the definition of $J_{t}$ in (2.9) will play an essential role here; we shall use in particular the following two properties of the sets $J_{t}$ :
if $(\alpha+\tilde{\alpha}, \beta+\tilde{\beta}) \in J_{t}$ and $\langle\bar{\beta}, L\rangle \leq|\tilde{\alpha}| k+\langle\tilde{\beta}, L\rangle$
then $\quad(\alpha, \beta+\bar{\beta}) \in \mathrm{J}{ }_{\mathrm{t}-|\tilde{\alpha}| \mathrm{k}-\langle\tilde{\beta}, \mathrm{L}\rangle+\langle\bar{\beta}, \mathrm{L}\rangle}$;

$$
\begin{align*}
& \text { if } \left.|\alpha+\tilde{\alpha}| k \leq(1+h) m \quad, \quad(\alpha+\tilde{\alpha}, \beta) \in J_{t} \text { and }<\tilde{\beta}, \mathrm{L}\right\rangle \leq|\tilde{\alpha}| k  \tag{2.26}\\
& \text { then }(\alpha, \beta+\beta) \in J_{t-|\tilde{\alpha}| k} .
\end{align*}
$$

Proof of Lemma 2.3. The expression $[P, \phi] D_{z}^{\mu} f$ in (2.17) is a linear combination of a finite number of terms of the form

$$
\begin{equation*}
x^{\gamma}\left(D_{z}^{\mu "} \phi\right) D_{z}^{\mu^{\prime}+\mu_{f}}, \tag{2.27}
\end{equation*}
$$

where $\left(\mu^{\prime}+\mu^{\prime \prime}, \gamma\right) \in \mathcal{Y}, \mu^{\prime \prime} \neq 0$, and $\mu=\left(\alpha_{1}, \beta_{1}\right) \in J_{t} . \operatorname{split} \mu^{\prime}=\left(\alpha^{\prime}, \beta^{\prime}\right)$, $\mu^{\prime \prime}=\left(\alpha^{\prime \prime}, \beta^{\prime \prime}\right)$ and assume first $\alpha^{\prime \prime}=0$. If $\mu \in I_{m+(n-\nu) k}$ and if $t_{0}$ in the statement is sufficiently large the norm of the function (2.27) can be easily estimated by means of the term $\rho^{-m}\| \|_{f, \rho_{1}+\rho} \|_{t-m}$ in the right-hand side of (2.17). Therefore we may assume without loss of generality $\left|\alpha_{1}\right| k+\left\langle\beta_{1}, L\right\rangle \geq m+(n-\nu) k$; in this case we can write $\left(\alpha_{1}, \beta_{1}\right)$ in the form $\left(\alpha_{1}^{\prime}+\alpha_{1}^{\prime \prime}, \beta_{1}^{\prime}+\beta_{1}^{\prime \prime}\right)$ and $\beta^{\prime}$ in the form $\left(\beta_{2}^{\prime}, \beta_{2}^{\prime \prime}\right)$, with $\left\langle\beta_{2}^{\prime}, L\right\rangle\langle(n-\nu) k$, in such a way that $| \alpha_{1}^{\prime \prime} \mid k+\left\langle\beta_{1}^{\prime \prime}, L\right\rangle=\left\langle\beta^{\prime \prime}+\beta_{2}^{\prime}, L\right\rangle$. Regrouping the derivatives in (2.27), we obtain
where $\left(\alpha_{1}^{\prime}, \beta_{1}^{\prime}+\beta_{2}^{\prime}\right) \in J_{t-j}$ with $j=\langle\beta ", L\rangle$, in view of (2.25). On the other hand, if we choose $\beta_{1}^{\prime \prime}, \beta_{2}^{\prime \prime}$ suitably, then the components of $\beta_{1}^{\prime \prime+}+\beta_{2}^{\prime \prime}$ satisfy

$$
\begin{equation*}
\left(\beta_{1}^{\prime \prime}+\beta_{2}^{\prime \prime}\right)_{q} L_{q} / k \in z_{+}, q=1, \ldots, n-\nu \tag{2.29}
\end{equation*}
$$

Therefore $\left(\alpha^{\prime}+\alpha_{1}^{\prime \prime}, \beta_{1}^{\prime \prime}+\beta_{2}^{\prime \prime}, \gamma\right) \in \mathcal{X l}$ and, in view of (2.3), the norm of the function in (2.28) is estimated by the term in the right-hand side of (2.17) at which $j=\langle\beta ", L\rangle$.
If $\alpha " \neq 0$, then in (2.27) $D_{z}^{\mu "} \phi=0$ for $|x|<1, \quad$ according to Lemma 2.1. Thus in all the estimates one can assume that the power of $\gamma$ in (2.27) is maximal, i.e. $|\gamma| k=h m$, and repeating the preceding arguments we find easily that for $\left|\alpha_{1}\right| k+\left\langle\beta_{1}, L\right\rangle$ sufficiently large the norm of (2.27) is estimated by the term of (2.17) in which $j=|\alpha| k+\langle\beta ", L\rangle$.

Proof of Lemma 2.4. The expression $\left[P, D_{z}^{\mu} f\right]$ in (2.18) consists of the sum of the terms

$$
\begin{equation*}
\left(D_{x}^{\alpha "} D_{y}^{\beta "} a_{\alpha \beta \gamma}\right)\left(D_{x}^{\alpha^{\prime \prime}} x^{\gamma}\right) D_{x}^{\alpha} D_{y}^{\beta}\left(D_{x}^{\alpha \prime} D_{y}^{\beta^{\prime}} f\right), \tag{2.30}
\end{equation*}
$$

where $\left(\alpha^{\prime}+\alpha^{\prime \prime}+\alpha^{\prime \prime}, \beta^{\prime}+\beta^{\prime \prime}\right)=\left(\alpha_{1}, \beta_{1}\right)=\mu \in J_{t},|\alpha "| k \leq h m$, and $(\alpha, \beta, \gamma) \in \gamma Y L$. If $|\alpha "| k+\langle\beta ", L\rangle=t_{2}$ and $|\alpha "| k=t_{3}$, then their number does not exceed $c j_{t!/} t_{2}!(t-j)!$, where $j=t_{2}+t_{3}$ and $c$ is a suitable constant. Then, in view of (2.11), it will be sufficient to check that for $j \neq 0$

$$
\begin{equation*}
\left\|\left(D_{x}^{\alpha " '} x_{x}^{\gamma}\right) D_{x}^{\alpha+\alpha}{ }_{D_{y}}^{\beta+\beta^{\prime}}{ }_{f}\right\|_{L^{2}\left(B_{\rho_{1}+\rho}\right)} \leq c\| \| f, \rho_{1}+\rho\| \|_{t-j} \tag{2.31}
\end{equation*}
$$

The expression $D_{x}^{\alpha " '} x^{\gamma}$ is nonzero only in the case when each component of $\gamma$ does not exceed the corresponding component of $\alpha^{\prime \prime \prime}$; hence $\gamma^{\prime}=\gamma-\alpha " ' \in \mathbb{Z}_{+}^{\nu}$ is well defined. Since $D_{x}^{\alpha " '} x^{\gamma}$ is proportional to $x^{\gamma^{\prime}}$, we are reduced to prove that every triple of multi-indices $\left(\alpha+\alpha^{\prime}, \beta+\beta^{\prime}, \gamma^{\prime}\right)$ can be written in the form

$$
\begin{equation*}
\left(\alpha+\alpha^{\prime}, \beta+\beta^{\prime}, \gamma^{\prime}\right)=\left(\alpha_{2}, \beta_{2}, \gamma^{\prime}\right)+\left(\alpha_{3}, \beta_{3}, 0\right) \tag{2.32}
\end{equation*}
$$

where

$$
\begin{equation*}
\left(\alpha_{2}, \beta_{2}, \gamma^{\prime}\right) \in \gamma \gamma\left[\text { and }\left(\alpha_{3}, \beta_{3}\right) \in J_{t-j}\right. \tag{2.33}
\end{equation*}
$$

Assume first $\left|\alpha^{\prime}\right| k \geq\langle\beta, L\rangle$; then we can write $\alpha+\alpha^{\prime}$ in the form $\alpha_{2}+\alpha_{3}$, where $\left|\alpha_{2}\right| k=|\alpha| k+\langle\beta, L\rangle$ (this is possible since $\langle\beta, L\rangle$ is a multiple of $k$ ). If we take $\beta_{2}=0$ and $\beta_{3}=\beta+\beta^{\prime}$, then the relation (2.32) holds and clearly $\left(\alpha_{2}, \beta_{2}, \gamma^{\prime}\right) \in J \not C /$, whereas $\left(\alpha_{3}, \beta_{3}\right) \in J_{t-j}$ follows from (2.25).
Assume now $\left|\alpha^{\prime}\right| k \ll \beta, L>$ and $\left|\alpha^{\prime \prime}\right| k \leq\langle\beta, L\rangle$; then we can write $\beta+\beta^{\prime}$ in the form of a sum $\beta_{2}+\beta_{3}$, where $\left\langle\beta_{2}, L\right\rangle=\langle\beta, L\rangle-|\alpha "| k$ and the components of $\beta_{2}$ satisfy:

$$
\begin{equation*}
\left(\beta_{2}\right)_{q} L_{q} / k \in \mathbb{Z}_{+}, q=1, \ldots, n-\nu \tag{2.34}
\end{equation*}
$$

Let us take $\alpha_{2}=\alpha, \alpha_{3}=\alpha$. Then the identity (2.32) is valid and clearly $\left(\alpha_{2}, \beta_{2}, \gamma^{\prime}\right) \in \mathcal{V Z}$. On the other hand we have in this case $\left|\alpha^{\prime}+\alpha^{\prime \prime}\right| k \leq(1+h) m$; then we may apply (2.26) and from $\left(\alpha^{\prime}+\alpha^{\prime \prime}, \beta^{\prime}\right) \in J_{t-t_{2}}$ we deduce $\left(\alpha_{3}, \beta_{3}\right) \in J_{t-j}$. Finally, if $\left|\alpha^{\prime}\right| k \ll \beta, L><\left|\alpha^{\prime \prime}\right| k$ we set $\left(\alpha_{2}, \beta_{2}\right)=(\alpha, 0),\left(\alpha_{3}, \beta_{3}\right)=$ $=\left(\alpha^{\prime}, \beta+\beta^{\prime}\right)$, and the relations (2.32), (2.33) follow easily from the preceding arguments.
