## 1. Introduction

An arrangement of hyperplanes is a finite collection of C-linear subspace of dimension $(l-1)$ in $\mathbf{C}^{l}$. For such an arrangement $\mathscr{A}$, there is a natural projective arrangement $\mathscr{A}^{*}$ of hyperplanes in $\mathbf{C P}^{l-1}$ associated to it. Let $M(\mathscr{A})=\mathbf{C}^{l}-\bigcup\{H: H \in \mathscr{A}\}$ and $M\left(\mathscr{A}^{*}\right)=\mathbf{C P}^{l-1}-\bigcup\left\{H^{*}: H^{*} \in \mathscr{A}^{*}\right\}$. Then it is clear that $M(\mathscr{A})=M\left(\mathscr{A}^{*}\right) \times \mathbf{C}^{*}$. The central problem in the theory of arrangements is to find connections between the topology or differentiable structure of $M(\mathscr{A})\left(\right.$ or $\left.M\left(\mathscr{A}^{*}\right)\right)$ and the combinatorial geometry of $\mathscr{A}$.

The study of the topology of $M(\mathscr{A})$ is important both in the theory of hypergeometric functions. (See the work of Gelfand [Ge] and his subsequent papers, the work of Deligne and Mostow [De-Mo] and subsequent papers by Mostow) and in the singularity theory ([Ar], [Br], [De] and also [Ca].). Moreover, it plays a role in some interesting problems in algebraic geometry (see especially the works of Hirzebruch [Hi] and Moishezon [Mo].).

Let $M_{l}$ denote the braid space with $l$ strands i.e., $M_{l}$ is the complement of complexified braid arrangement $A_{l}$ defined by $Q=\Pi_{1 \leqslant i<j \leqslant l}\left(z_{i}-z_{j}\right)$. In 1969, Arnold [Ar] was able to calculate the Poincaré polynomial of the pure braid space $M_{l}$ and the cohomology ring structure of $H^{*}\left(M_{l}\right)$. In general for an arbitrary arrangement $\mathscr{A}$, define holomorphic differential forms $\omega_{H}=(1 /(2 \pi i))\left(\mathrm{d} \alpha_{H} / \alpha_{H}\right)$ where $\alpha_{H}$ is the linear form defining the hyperplane $H$ for $H \in \mathscr{A}$ and let [ $\omega_{H}$ ] denote the corresponding cohomology class. Let $R(\mathscr{A})=\oplus_{p=0}^{l} R_{p}$ be the graded $\mathbf{C}$-algebra of holomorphic differential forms on $M(\mathscr{A})$ generated by the $\omega_{H}$ and 1 . Arnold conjectured that the natural map $\eta \rightarrow[\eta]$ of $R(\mathscr{A}) \rightarrow H^{*}(M(\mathscr{A}), \mathbf{C})$ is an isomorphism of graded algebras. This was proved by Brieskorn [Br] in 1971 who showed in fact that the Zsubalgebra of $R(\mathscr{A})$ generated by the forms $\omega_{H}$ and 1 is isomorphic to the singular cohomology $H^{*}(M(\mathscr{A}), \mathbf{Z})$. Although Brieskorn proved the Arnold conjecture, it was not known whether the algebra $R(\mathscr{A})$ is determined by the combinatorial data of $\mathscr{A}$, since the linear forms enter the definition of $R(\mathscr{A})$. In 1980, Orlik and Solomon [Or-So1] showed that for an arbitrary arrange-

[^0]ment $\mathscr{A}$ the Poincarté polynomial of $M(\mathscr{A})$ equals the Poincaré polynomial of $\mathscr{A}$. Hence the betti number of $M(\mathscr{A})$ is combinatorially determined. They also introduced a graded algebra $A(\mathscr{A})$ in [Or-So1]. It is a combinatorial invariant of $\mathscr{A}$. The main result of [Or-So1] asserts that there is an isomorphism of algebras $A(\mathscr{A}) \simeq R(\mathscr{A})$. This, together with the Brieskorn solution to Arnold's conjecture, imply that the cohomology ring $H^{*}(M(\mathscr{A}), \mathbf{C})$ is a combinatorial invariant of $\mathscr{A}$.

The next difficult unsolved problems involve the homotopy groups of $M(\mathscr{A})$. In a Bourbaki Seminar talk, Brieskorn [Br] generalized Arnold's results. He replaced the symmetric group and the braid arrangement by a Coxeter group $W$ acting in $\mathbf{R}^{l}$. Then $A$ acts as a reflection group in $\mathbf{C}^{l}$. Let $\mathscr{A}=\mathscr{A}(W)$ be its reflection arrangement. Brieskorn conjectured that $\mathscr{A}(W)$ is a $K(\pi, 1)$ arrangement for all Coxeter groups $W$. He proved this for some of the groups by representing $M$ as the total space of a sequence of fibrations. Deligne [De] settled the question by proving that complement of complexification of real simplicial arrangement is $K(\pi, 1)$. This result proves Brieskorn's conjecture because the arrangement of a Coxeter group is simplicial. Shepherd and Todd [Sh-To] classified finite irreducible complex reflection groups. Recall that real reflection groups are also called Coxeter groups because finite irreducible real reflection groups were classified by Coxeter [Co]. Every real reflection group may be viewed as a complex reflection group. There are examples of complex reflection groups which are not Coxeter groups. Orlik and Solomon [Or-So2] conjectured that all the complex reflection arrangements are $K(\pi, 1)$. For a subclass of irreducible complex reflection groups called Shepherd groups, this was proved by Orlik and Solomon [Or-So3]. The conjecture is still open for the remaining irreducible complex reflection groups. In [Sa1], Salvetti made a fundamental contribution to the understanding of the higher homotopy in the complement of an arrangement. He considered a union of real affine hyperplanes in $\mathbf{C}^{l}$ with complement $M$ and constructed explicitly a $C W$-complex $X \subset M$ of dimension $l$ with the homotopy type of $M$. Recently, he introduced a class of cellular complexes by which Deligne's result is re-proved and generalized [Sa3]. Orlik [Or] has constructed for all arrangements a finite simplicial complex of the homotopy type of $M$. In [Ar], Arvola exhibits a simplicial homotopy equivalence between Salvetti complex and Orlik complex in the case of real arrangement. Recently, Björner and Ziegler presented a general method for constructing regular complexes with the homotopy type of $M(\mathscr{A})$. They generalized the construction of Salvetti [Sa1] to complex arrangements, gave a new proof of Brieskorn-Orlik-Solomon theorem and investigated a class of topological deformed complex arrangements [ $\mathrm{Bj}-\mathrm{Zi}$ ].

The difficult and still unsolved problem is whether the topological or diffeomorphic type of complement $M(\mathscr{A})$ of an arrangement is combinatorial
in nature. The purpose of this paper is to give a partial solution to this problem. Let $\mathscr{A}$ be a central arrangement in $\mathbf{C}^{3}$ and $\mathscr{A}^{*}$ be the corresponding projective arrangement in $\mathbf{C} \mathbf{P}^{2}$. We can define a graph $G\left(\mathscr{A}^{*}\right)$ which depends only on the combinatorial data of the arrangement. An arrangement $\mathscr{A}^{*}$ is called a nice arrangement if after removing pairwise disjoint star shaped subgraphs of $G$, the graph becomes a forest.

MAIN THEOREM. Let $\mathscr{A}_{1}$ and $\mathscr{A}_{2}$ be two central nice arrangements in $\mathbf{C}^{3}$ and $\mathscr{A}_{1}^{*}, \mathscr{A}_{2}^{*}$ be the corresponding projective arrangements in $\mathbf{C P}^{2}$. If the lattices of $\mathscr{A}_{1}$ and $\mathscr{A}_{2}$ are isomorphic, then the complements of the projective arrangements $A_{1}^{*}, \mathscr{A}_{2}^{*}$ in $\mathbf{C P}^{2}$ are diffeomorphic to each other.

The proof of our Main Theorem above actually works for much general arrangements. We shall give an example in Section 4 to demonstrate this. Any arrangement such that the proof of our Main Theorem works is called a good arrangement. Given a projective arrangement $\mathscr{A}^{*}$ in $\mathbf{C} \mathbf{P}^{2}$, it is important to find a presentation of the fundamental group of the complement $M\left(\mathscr{A}^{*}\right)$ and determine whether $\pi_{1}\left(M\left(\mathscr{A}^{*}\right)\right)$ depends only on the lattice $L(\mathscr{A})$. If $\mathscr{A}^{*}$ is the complexification of a real arrangement, then this problem was solved by Randall [Ra]. The following corollary is an immediate application of our Main Theorem above.

COROLLARY. A presentation of the fundamental group of the complement $M\left(\mathscr{A}^{*}\right)$ of a nice arrangement in $\mathbf{C P}^{2}$ can be explicitly written and it depends only on the lattice of $\mathscr{A}$.

The second author would like to thank M. Falk for his invitation to participate in the AMS-CBMS on Arrangement of Hyperplanes at Northern Arizona University in 1988. The Main Theorem was announced in the survey paper [Ji-Ya]. The Main Theorem is based on the observation that the diffeomorphic types of the complements of arrangements are the same in a one parameter family of arrangements with isomorphic lattices. This follows immediately from a Teissier's numerical characterization of Whitney condition [Te] and Thom's first isotopy theorem. It was also observed independently during the AMS-CBMS on Arrangement of Hyperplanes by Randell [Ra]. Recently Arvola [Ar] has determined $\pi_{1}\left(M\left(\mathscr{A}^{*}\right)\right.$ ), from a certain planar graph. In Section 2, we shall recall some terminology in abstract lattice theory. In Section 3 we shall prove the Main Theorem. For each projective arrangement in $\mathbf{C P}{ }^{2}$, we associate a variety in $\left(\mathbf{C P}^{1}\right)^{p}$ where $p$ is the number of lines in the graph $G\left(\mathscr{A}^{*}\right)$. This variety plays an important role in studying the diffeomorphic type of arrangement. In Section 4 we shall study two examples of these varieties.

## 2. Arrangement $\mathscr{A}$ and its lattice $L(\mathscr{A})$

We begin by recalling some terminology in lattice theory.
DEFINITION 2.1. Let $P$ be a poset. An upper bound of a subset $X$ of $P$ is an element $a \in P$ such that $x \leqslant a$ for every $x \in X$. The least upper bound is an upper bound less than or equal to every other upper bound; it is denoted by $\sup X$. The notion of lower bound of $X$ ard greatest lower bound $(\inf X)$ of $X$ are defined dually.

DEFINITION 2.2. A lattice is a poset $P$ any two of whose elements have a greatest lower bound or "meet" denoted by $x \wedge y$, and a lowest upper bound or "join" denoted by $x \vee y$.
DEFINITION 2.3. An element $y$ covers an element $x$ in a lattice $L$ if and only if $x<y$, but $x<z<y$ for no element $z$ in $L$.

DEFINITION 2.4. A chain in a lattice $L$ is any linearly ordered subset of $L$.
DEFINITION 2.5. A lattice having no infinite chains is said to be semimodular whenever it has the covering property: for all lattice elements $x, y$, if $x$ and $y$ cover $x \wedge y$, then $x \vee y$ covers $x$ and $y$.

DEFINITION 2.6. Let $L$ be a lattice with finite elements. The length of a chain $C$ of $L$ is defined as $|C|-1$. The rank of $a \in L$, denoted by $r(a)$, is the length of the longest chain in $L$ below $a$. Let $\hat{0}=\inf L$ and $\hat{1}=\sup L$. Then $r(\hat{0})=0$. The rank of $L$ (rank $L$ ) is defined to be $r(\hat{1})$. If $a$ in $L$ has rank 1 , then $a$ is called a point or an atom of the lattice.

DEFINITION 2.7. A point lattice (or atomic lattice) is a lattice in which every element is a join of points. A geometric lattice is a semimodular point lattice with no infinite chains.

In this paper an arrangement $\mathscr{A}$ is a finite collection of hyperplanes $\left\{H_{1}, \ldots, H_{n}\right\}$ through the origin in $\mathbf{C}^{l}$. The lattice $L(\mathscr{A})$ is the set of all intersections of subsets of $\mathscr{A}$, partially ordered by reverse inclusion i.e. $X \leqslant Y \leftrightarrow Y \subseteq X$. The rank function $r$ on $L(\mathscr{A})$ is $r(X)=\operatorname{codim} X=$ $l-\operatorname{dim}_{\mathbf{c}} X$ for $X \in L(\mathscr{A})$, each $H_{i}$ is an atom of $L(\mathscr{A})$, the join is by $X \vee Y=X \cap Y$ and the meet is by $X \wedge Y=\bigcap\{Z: Z \in L(\mathscr{A}), X \cup Y \subset Z\}$.

LEMMA 2.8. Let $\mathscr{A}$ be an arrangement. Then
(i) for every $X \in L(\mathscr{A})$ all chains from $X$ to $\mathbf{C}^{l}$ have the same cardinality,
(ii) every element of $L(\mathscr{A})-\left\{\mathbf{C}^{l}\right\}$ is join of atoms,
(iii) for all $X, Y \in L(\mathscr{A})$ the rank function satisfies

$$
r(X \wedge Y)+r(X \vee Y) \leqslant r(X)+r(Y)
$$

Thus $L(\mathscr{A})$ is a geometric lattice.

DEFINITION 2.9. Let $L_{p}=L_{p}(\mathscr{A}):=\{X \in L(\mathscr{A}): r(X)=p\}$. The Hasse diagram of $L(\mathscr{A})$ has vertices labelled by the elements of $L(\mathscr{A})$ and arranged on levels $L_{p}, p \geqslant 0$. Suppose $X \in L_{p}$ and $Y \in L_{p+1}$. An edge connects $X$ with $Y$ if $X<Y$.

EXAMPLE 2.10. Let $\mathscr{A}$ be an arrangement of hyperplanes in $\mathbf{C}^{3}$ consisting of the elements

$$
\begin{aligned}
& \left\{(x, y, z) \in \mathbf{C}^{3}: x=y\right\},\left\{(x, y, z) \in \mathbf{C}^{3}: x=-y\right\} .\left\{(x, y, z) \in \mathbf{C}^{3}: y=z\right\} \\
& \left\{(x, y, z) \in \mathbf{C}^{3}: y=-z\right\},\left\{(x, y, z) \in \mathbf{C}^{3}: x=z\right\},\left\{(x, y, z) \in \mathbf{C}^{3}: x=-z\right\} .
\end{aligned}
$$

Figure 2.1 shows the Hasse diagram of $L(\mathscr{A})$.

## 3. Proof of the Main Theorem

In this section, we denote $\mathscr{A}$ the (central) arrangement of hyperplanes in $\mathbf{C}^{3}$ and $\mathscr{A}^{*}$ its associated projective arrangement of hyperplanes in $\mathbf{C P}^{2}$. Let $\left.L \mathscr{A}\right)$ be the lattice associated with $\mathscr{A}$.

DEFINITION 3.1. A point $p$ in $\mathbf{C P}^{2}$ is of multiplicity $k$ in $\mathscr{A}^{*}$ if $p$ is the intersection of exactly $k$ lines in $\mathscr{A}^{*}$. Let $t_{k}\left(\mathscr{A}^{*}\right)$ be the number of $k$-tuple points in the arrangement $\mathscr{A}^{*}$. Then the complexity of $\mathscr{A}^{*}$ is defined to be $\Sigma_{k \geqslant 3}(k-2) t_{k}\left(\mathscr{A}^{*}\right)$.

Let us define the graph $G$ from an arrangement $\mathscr{A}^{*}$ in $\mathbf{C P}^{2}$. Let $V G$ be the set of vertices of $G$ consisting of all points of $\mathscr{A}^{*}$ with multiplicity greater than 2. Let $E G$ be the set of edges of $G$. Each edge in $E G$ is a pair of distinct vertices $\left(v_{1}, v_{2}\right)$ of $V G$ which span a line $\left\langle v_{1}, v_{2}\right\rangle$ of $\mathscr{A}^{*}$. A reduced path of $G$ is denoted by a $(n+1)$-tuple $\left(v_{0}, \ldots, v_{n}\right)$ such that $\left(v_{i-1}, v_{i}\right) \in E G$ and

Fig. 2.1. Hasse diagram of Example 2.10.
$\left\langle v_{i-1}, v_{i}\right\rangle \neq\left\langle v_{i}, v_{i+1}\right\rangle$ for $i=1, \ldots, n-1$. Furthermore, it is a loop when $v_{0}=v_{n}, n \geqslant 3 . G$ is called a forest if it does not contain such a loop.

For a $v_{0} \in V G$, define a subgraph $\operatorname{St}\left(v_{0}\right)$ of $G$ by setting $V \operatorname{St}\left(v_{0}\right)=$ $\left\{v_{0}\right\} \cup\left\{v \in V G:\left\langle v_{0}, v\right\rangle \in \mathscr{A}^{*}\right\}$ and $\operatorname{ESt}\left(v_{0}\right)=\left\{(v, w) \in E G: v=v_{0}\right.$ or $w=0$, otherwise $\left.\langle v, w\rangle=\left\langle v_{0}, v\right\rangle\right\}$.

Fig. 3.1. A nice arrangement $S^{*}$ including the line in infinite.

Fig. 3.2. The graph $G$ of $\mathscr{A}^{*}$.

Fig. 3.3. The graph $G^{\prime}=G-\left(E \operatorname{St}\left(v_{1}\right) \cup\left\{v_{1}\right\} \cup E \operatorname{St}\left(v_{2}\right) \cup\left\{v_{2}\right\}\right)$.

DEFINITION 3.2. An arrangement $\mathscr{A}^{*}$ in $\mathbf{C P}^{2}$ is said to be nice if the graph $G$ from $\mathscr{A}^{*}$ has the following property: There are $v_{1}, \ldots, v_{m} \in V G$ such that $\operatorname{St}\left(v_{1}\right), \ldots, \operatorname{St}\left(v_{m}\right)$ are pairwise disjoint in $G$ and $G^{\prime}=G-\bigcup_{i=1}^{m}\left(E \operatorname{St}\left(v_{i}\right) \cup\left\{v_{i}\right\}\right)$ is a forest.

THEOREM 3.3. Let $\mathscr{A}_{0}^{*}$ and $\mathscr{A}_{1}^{*}$ be two nice projective arrangements in $\mathbf{C P}^{2}$. If the lattices of $\mathscr{A}_{0}$ and $\mathscr{A}_{1}$ are isomorphic, then the complements $M\left(\mathscr{A}_{0}^{*}\right)$ and $M\left(\mathscr{A}_{1}^{*}\right)$ of the projective arrangements $\mathscr{A}_{0}^{*}$ and $\mathscr{A}_{1}^{*}$ in $\mathbf{C P}{ }^{2}$ are diffeomorphic to each other.

Proof. We represent the two arrangements as $\mathscr{A}_{1}^{*}=\left\{H_{1}, H_{2}, \ldots, H_{n}\right\}$ and $\mathscr{A}_{\mathrm{O}}^{*}=\left\{G_{1}, G_{2}, \ldots, G_{n}\right\}$ where $H_{i}=\left(h_{i 1}, h_{i 2}, h_{i 3}\right)$ and $G_{i}=\left(g_{i 1}, g_{i 2}, g_{i 3}\right)$ are in $\mathbf{C P}^{2}$. We shall construct a one-parameter family of arrangements $\mathscr{A}^{*}(t)$ such that $\mathscr{A}^{*}(0)=\mathscr{A}_{0}^{*}, \mathscr{A}^{*}(1)=\mathscr{A}_{1}^{*}$ and $L(\mathscr{A}(t)) \equiv L\left(\mathscr{A}_{0}\right)$ for all $t \in[0,1]$.

Let $\mathscr{A}^{*}=\left\{F_{1}, F_{2}, \ldots, F_{n}\right\}$ where $F_{i}=x_{i} G_{i}+y_{i} H_{i}$ for some $x_{i}, y_{i} \in \mathbf{C}$ such that $F_{i}$ is in $\mathbf{C P}^{2}, i=1,2, \ldots, n$. Let $I=\{(i, j, k): 1 \leqslant i<j<k \leqslant n\}$. So $|I|=\binom{n}{3}$. Consider any triple $\left(F_{i}, F_{j}, F_{k}\right),(i, j, k) \in I$. Denote the matrix

$$
\left[\begin{array}{lll}
x_{i} g_{i 1}+y_{i} h_{i 1} & x_{i} g_{i 2}+y_{i} h_{i 2} & x_{i} g_{i 3}+y_{i} h_{i 3} \\
x_{j} g_{j 1}+y_{j} h_{j 1} & x_{j} g_{j 2}+y_{j} h_{j 2} & x_{j} g_{j 3}+y_{j} h_{j 3} \\
x_{k} g_{k 1}+y_{k} h h_{k 1} & x_{k} g_{k 2}+y_{k} h_{k 2} & x_{k} g_{k 3}+y_{k} h_{k 3}
\end{array}\right]
$$

by $\left[F_{i} F_{j} F_{k}\right]$ and its determinant by $\left|F_{i} F_{j} F_{k}\right|$. We now can write

$$
\begin{align*}
\left|F_{i} F_{j} F_{k}\right|= & \left|G_{i} G_{j} G_{k}\right| x_{i} x_{j} x_{k}+\left|H_{i} G_{j} G_{k}\right| y_{i} x_{j} x_{k} \\
& +\left|G_{i} H_{j} G_{k}\right| x_{i} y_{j} x_{k}+\left|G_{i} G_{j} H_{k}\right| x_{i} x_{j} y_{k} \\
& +\left|G_{i} H_{j} H_{k}\right| x_{i} y_{j} y_{k}+\left|H_{i} G_{j} H_{k}\right| y_{i} x_{j} y_{k} \\
& +\left|H_{i} H_{j} G_{k}\right| y_{i} y_{j} x_{k}+\left|H_{i} H_{j} H_{k}\right| y_{i} y_{j} y_{k} . \tag{3.1}
\end{align*}
$$

Since each two lines in $\mathbf{C P}^{2}$ meet exactly at one point, to get $L(\mathscr{A}) \equiv L\left(\mathscr{A}_{0}\right)$, it is sufficient to have the following

For any $(i, j, k) \in I,\left|F_{i} F_{j} F_{k}\right|=0$ if and only if $\left|G_{i} G_{j} G_{k}\right|=0$
Let $l=\Sigma_{j \geqslant 3}\binom{j}{3} t_{j}\left(\mathscr{A}_{1}^{*}\right)$. By (3.2), we need to have $l$ equations and $\binom{n}{3}-l$ inequalities

$$
\begin{align*}
& P_{1}=0, \ldots, P_{l}=0  \tag{3.3}\\
& Q_{1} \neq 0, \ldots, Q_{\left(\frac{3}{3}\right)-l} \neq 0 \tag{3.4}
\end{align*}
$$

Both $P_{i}$ and $Q_{j}$ have the forms like (3.1). But for $P_{i}$, the first term and the last term are zero since $\left|G_{i} G_{j} G_{k}\right|=\left|H_{i} H_{j} H_{k}\right|=0$ by (3.2). Among $P_{1}, \ldots, P_{l}$ at most $c\left(\mathscr{A}_{1}\right)=\Sigma_{j \geqslant 3}(j-2) t_{j}\left(\mathscr{A}_{1}^{*}\right)$ of them are independent. To see this, we consider a $j$-tuple point $V(j \geqslant 3)$. Let $F_{1}, \ldots, F_{j}$ be the lines of $\mathscr{A}^{*}$ passing through $V$. We have $\binom{j}{3}$ equations $\left(\left|F_{1} F_{2} F_{3}\right|=0, \ldots\right.$, etc). Since $\left\{F_{1}, \ldots, F_{j}\right\}$ can be linearly generated by $F_{1}$ and $F_{2}$, the $\binom{j}{3}$ equations is reduced equivalently to $j-2$ equations $\left|F_{1} F_{2} F_{i}\right|=0$ for $i=3, \ldots, j$. Now consider all $j$-tuple points $(j \geqslant 3)$. We have a system of $c\left(\mathscr{A}_{1}\right)$ equations, say $\left\{P_{1}=0, \ldots, P_{c\left(\mathscr{A}_{1}\right)}=0\right\}$ which is equivalent to $\left\{P_{1}=0, \ldots, P_{l}=0\right\}$.

As we observed before, each $\operatorname{Pr}$ can be written like

$$
\begin{gather*}
\operatorname{Pr}=a_{r} y_{i r} x_{j r} x_{k r}+b_{r} x_{i r} y_{j r} y_{j r} x_{k r}+c_{r} x_{i r} x_{j r} y_{k r}^{k}+\alpha_{r} x_{i r} y_{j r} y_{k r} \\
+\beta_{r} y_{i r} x_{j r} y_{k r}+\gamma_{r} y_{i r} y_{j r} x_{k r} \tag{3.5}
\end{gather*}
$$

where $a_{r}=\left|H_{i r} G_{j r} G_{k r}\right|$ etc. Replacing $\mathscr{A}_{0}^{*}$ by $\varphi\left(\mathscr{A}_{0}^{*}\right)$ if necessary where $\varphi: \mathbf{C P}^{2} \rightarrow \mathbf{C P}^{2}$ is a complex analytic automorphism, we assume without loss of generality that any one (two) line(s) in $\mathscr{A}_{0}^{*}$ and any two (one) line(s) in $\mathscr{A}_{1}^{*}$ do not intersect at a point. This means that $a_{r} b_{r} c_{r} \alpha_{r} \beta_{r} \gamma_{r} \neq 0$ for all $r=1, \ldots, c\left(\mathscr{A}_{1}\right)$.

Note that $P_{r}$ is viewed as polynomial in $\left(\left(x_{1}: y_{1}\right), \ldots,\left(x_{n}: y_{n}\right)\right) \in\left(\mathbf{C} \mathbf{P}^{1}\right)^{n}$. For each $r$, indices $i_{r}, j_{r}, k_{r}$ are pairwise distinct and $\left(i_{r}, j_{r}, k_{r}\right) \neq\left(i_{s}, j_{s}, k_{s}\right)$ for $r \neq s$ where $1 \leqslant i_{r}, j_{r}, k_{r}, i_{s}, j_{s}, k_{s} \leqslant n$ and $\leqslant r, s \leqslant c\left(\mathscr{A}_{1}\right)$. Before we can continue our proof, we need to introduce the following concept.

DEFINITION 3.4. $\left(x_{i}: y_{i}\right) \in \mathbf{C} \mathbf{P}^{1}$ is called irregular for the following equation

$$
\begin{align*}
a y_{i} x_{j} x_{k} & +b x_{i} y_{j} x_{k}+c x_{i} x_{j} y_{k}+\alpha x_{i} y_{j} y_{k}+\beta y_{i} x_{j} y_{k} \\
& +\gamma y_{i} y_{j} x_{k} \tag{3.6}
\end{align*}=0 \quad(a b c \alpha \beta \gamma \neq 0)
$$

if $\left(a y_{i}\right) x_{j} x_{k}+\left(b x_{i}+\gamma y_{i}\right) y_{j} x_{k}+\left(c x_{i}+\beta y_{i}\right) x_{j} y_{k}+\left(\alpha x_{i}\right) y_{j} y_{k}$ is a reducible polynomial of the other two variables $\left(x_{j}: y_{j}\right)$ and $\left(x_{k}: y_{k}\right)$. Otherwise we call $\left(x_{i}: y_{i}\right)$ regular for the equation (3.6).

LEMMA 3.5. Assume $\left(\left(x_{1}: y_{1}\right),\left(x_{2}: y_{2}\right),\left(x_{3}: y_{3}\right)\right) \in\left(\mathbf{C P}^{1}\right)^{3}$ is a solution of (3.6). If $\left(x_{1}: y_{1}\right)$ is irregular, then either $\left(x_{2}: y_{2}\right)$ or $\left(x_{3}: y_{3}\right)$ is irregular for (3.6). If $\left(x_{1}: y_{1}\right)$ is regular, then $\left(x_{2}: y_{2}\right)$ and $\left(x_{3}: y_{3}\right)$ are either both regular or both irregular for (3.6). In other words, the number of irregulars cannot be 1 .

Proof. When $y_{1}=0$, (3.6) becomes

$$
b y_{2} x_{3}+c x_{2} y_{3}+\alpha y_{2} y_{3}=0
$$

which is irreducible. So if $\left(x_{1}: y_{1}\right)$ is irregular, then $x_{1} \neq 0$ and $y_{1} \neq 0$.
Write (3.6) as polynomial of $\left(x_{2}: y_{2}\right)$ and $\left(x_{3}: y_{3}\right)$

$$
\left(a y_{1}\right) x_{2} x_{3}+\left(b x_{1}+\gamma y_{1}\right) y_{2} x_{3}+\left(c x_{1}+\beta y_{1}\right) x_{2} y_{3}+\left(\alpha x_{1}\right) y_{2} y_{3}=0
$$

It is reducible if and only if

$$
\left(b x_{1}+\gamma y_{1}\right)\left(c x_{1}+\beta y_{1}\right)=a \alpha x_{1} y_{1}
$$

or

$$
\begin{equation*}
b c x_{1}^{2}+(b \beta+\gamma c-\alpha a) x_{1} y_{1}+\beta \gamma y_{1}^{2}=0 \tag{3.7}
\end{equation*}
$$

which has at most two roots of $\left(x_{1}: y_{1}\right)$. When $\left(x_{1}: y_{1}\right)$ is a root of the equation above, (3.6) becomes

$$
\left[\left(a y_{1}\right) x_{3}+\left(c x_{1}+\beta y_{1}\right) y_{3}\right]\left[x_{2}+\frac{\alpha x_{1}}{c x_{1}+\beta y_{1}} y_{2}\right]=0
$$

from which we have the solution to either $\left(x_{2}: y_{2}\right)=\left(-\alpha x_{1}: c x_{1}+\beta y_{1}\right)$ or $\left(x_{3}: y_{3}\right)=\left(-\left(c x_{1}+\beta y_{1}\right): a y_{1}\right)$.

In the first case, we have

$$
x_{1}=-\frac{x_{2}}{\alpha} \quad \text { and } \quad y_{1}=\frac{1}{\beta} y_{2}+\frac{c}{\alpha \beta} x_{2}
$$

Put these into (3.7) yields

$$
\begin{aligned}
& b c \beta x_{2}^{2}-\left(c x_{2}^{2}+\alpha x_{2} y_{2}\right)(b \beta+\gamma c-\alpha a)\left(y_{2}+\frac{c}{\alpha} x_{2}\right) \\
& \quad+\beta \alpha \cdot \frac{1}{\beta^{2}}\left(y_{2}^{2}+\frac{2 c}{\alpha} x_{2} y_{2}+\frac{c^{2}}{\alpha^{2}} x_{2}^{2}\right)=0 \\
& \Rightarrow b c \beta_{2}^{2}-\left(c x_{2}^{2}+\alpha x_{2} y_{2}\right)(b \beta+\gamma c-\alpha a) \\
& \quad+\left(\gamma c^{2} x_{2}^{2}+2 x \alpha \gamma x_{2} y_{2}+\gamma \alpha^{2} y_{2}^{2}\right)=0 \\
& \Rightarrow\left(b c \beta-c b \beta-\gamma c^{2}+\alpha c a+\gamma c^{2}\right) x_{2}^{2}+\left(-\alpha b \beta-\alpha \gamma c+\alpha^{2} a\right) \\
& \quad+2(\alpha \gamma) x_{2} y_{2}+\gamma \alpha^{2} y_{2}^{2}=0 \\
& \Rightarrow c a x_{2}^{2}+(a \alpha+\gamma c-b \beta) x_{2} y_{2}+\gamma \alpha y_{2}^{2}=0 .
\end{aligned}
$$

The last equation is a necessary and sufficient condition for $\left(x_{2}: y_{2}\right)$ being irregular of (3.6). For the second case, we have the same conclusion for $\left(x_{3}: y_{3}\right)$.

From the argument above we also have
LEMMA 3.6. There are at most two irregular $\left(x_{i}: y_{i}\right)$ of (3.6) for each $i=1,2$, 3. $(0: 1)$ and $(1: 0)$ are regular of $(3.6)$.

LEMMA 3.7. For each fixed regular $\left(x_{1}: y_{1}\right)$ of (3.6), the following relation prodcuces an automorphism of $\mathbf{C P}{ }^{1}$

$$
\binom{x_{3}}{y_{3}}=K\left(\begin{array}{cc}
-\beta y_{1}-c x_{1} & -\alpha x_{1}  \tag{3.8}\\
a y_{1} & b x_{1}+\gamma y_{1}
\end{array}\right)\binom{x_{2}}{y_{2}}, \quad K \in \mathbf{C}^{*}
$$

which sends regular values to regular values of (3.6). In particular $\left(x_{1}: y_{1}\right)=\left(x_{2}: y_{2}\right)=(0: 1)($ respectively $(1: 0))$ corresponds to $\left(x_{3}: y_{3}\right)=(0: 1)$ (respectively $(1: 0)$ ).

Proof.

$$
\left|\begin{array}{cc}
-\beta y_{1}-c x_{1} & -\alpha x_{1} \\
a y_{1} & b x_{1}+\gamma y_{1}
\end{array}\right|=-b c x_{1}^{2}-(b \beta+\gamma c-\alpha a) x_{1} y_{1}-\beta \gamma y_{1}^{2} .
$$

Since ( $x_{1}: y_{1}$ ) is a regular value, the above expression is nonzero by (3.7). So (3.8) is an automorphism of $\mathbf{C P}{ }^{1}$. Clearly (3.8) satisfies equation (3.6). By Lemma 3.5, the mapping (3.8) sends regular values of (3.6) to regular values of (3.6). The last statement of the lemma is obvious.

REMARK 3.8. Equation (3.8) is equivalent to equation (3.6). For we write (3.6) as

$$
\left(a y_{1} x_{2}+b x_{1} y_{2}+\gamma y_{1} y_{2}\right) x_{3}+\left(\alpha x_{1} y_{2}+\beta y_{1} x_{2}+c x_{1} x_{2}\right)=0
$$

Then $\left(x_{3}, y_{3}\right)=K\left(-\alpha x_{1} x_{2}-\beta y_{1} y_{2}-c x_{1} x_{2}, a y_{1} x_{2}+b x_{1} y^{2}+\gamma y_{1} y_{2}\right)$ which is (3.8). So if $\left(x_{1}: y_{1}\right)$ and $\left(x_{2}: y_{2}\right)$ are regular of (3.6), then there is a unique $\left(x_{3}: y_{3}\right)$ solved in terms of $\left(x_{1}: y_{1}\right)$ and $\left(x_{2}: y_{2}\right)$. We call such procedure "fixing two variables to solve the other" and such $\left(x_{1}: y_{1}\right),\left(x_{2}: y_{2}\right),\left(x_{3}: y_{3}\right)$ "solved variables". Let us now return to the proof of Theorem 3.3. Since $\mathscr{A}_{1}^{*}$ is a nice projective arrangement in $\mathbf{C P}^{2}$, there are $v_{1}, \ldots, v_{m} \in V G$, where $G$ is the graph of $\mathscr{A}_{1}^{*}$, such that $\operatorname{St}\left(v_{1}\right), \ldots, \operatorname{St}\left(\dot{v}_{m}\right)$ are disjoint pairwise in $G$ and

$$
G^{\prime}=G-\bigcup_{i=1}^{m}\left(E\left(\operatorname{St}\left(v_{i}\right)\right) \cup\left\{v_{i}\right\}\right)
$$

is a forest.
Suppose $m=1$. Assume that $v_{1}$ is a point of multiplicity $k$ in $\mathscr{A}_{1}^{*}$. Recall that by the definition of $G, k \geqslant 3$. Then there are $k$ variables appearing in $k-2$ equations of (3.6). Suppose that these variables are $\left(x_{1}: y_{1}\right), \ldots,\left(x_{k}: y_{k}\right)$ and $\left(x_{1}: y_{1}\right),\left(x_{2}: y_{2}\right)$ appear in each of these $k-2$ equations. We can fix $\left(x_{1}: y_{1}\right)$, $\left(x_{2}: y_{2}\right)$ to solve $\left(x_{3}: y_{3}\right), \ldots,\left(x_{k}: y_{k}\right)$.

The rest of the unsolved variables and equations in (3.5) correspond to the graph $G^{\prime}$ which is a forest. At each following step, we consider the graph formed by the vertices with unsolved variables. In each component of this graph we pick a vertex which is adjacent (in $G$ ) to a vertex whose variables are solved and apply the same procedure to solve its variables. (If there is a connected component of $G^{\prime}$ which is not connected with any vertices whose variables are solved, we pick any one of its vertices.) The set of vertices whose variables are solved and which lie in a same connected component of $G$ span a subgraph of $G$ which is connected. Thus we can solve all variables in terms of some variables without ambiguity since $G^{\prime}$ is a forest.

For the case $m=0$ or $m>1$ we apply the same procedure. All variables are presented as

$$
\left(\left(x_{1}: y_{1}\right), \ldots,\left(x_{n}: y_{n}\right)\right)=f\left(\left(x_{1}: y_{1}\right), \ldots,\left(x_{p}: y_{p}\right)\right)
$$

where each component of $f$ is a composition by some maps as (3.8). So they are homogeneous polynomial of $\left(x_{1}: y_{1}\right), \ldots,\left(x_{p}: y_{p}\right)$. Let $U:=\left(\mathbf{C P}^{1}\right)^{p}-$ $\left\{\left(\left(x_{1}: y_{1}\right), \ldots,\left(x_{p}: y_{p}\right)\right):\right.$ for some $1 \leqslant i \leqslant p,\left(x_{i}: y_{i}\right)$ is irregular of some equation
of (1) $\}$. By Lemma 3.6, $U$ is an open connected set of $\left(\mathbf{C P}^{1}\right)^{p}$. By Lemma 3.7, $f$ defines an embedding from $U \subset\left(\mathbf{C} \mathbf{P}^{1}\right)^{p}$ to $\left.(\mathbf{C P})^{1}\right)^{n}$. Since $U$ is irreducible, so is $f(U)$ irreducible. Observe that $(0: 1)^{n}=((0: 1), \ldots,(0: 1))$ and $(1: 0)^{n}=$ $((1: 0), \ldots,(1: 0))$ are contained in $f(U)$. We deduce that $(0: 1)^{n}$ and $(1: 0)^{n}$ are in the same irreducible component of $\left\{P_{1}=0, P_{2}=0, \ldots, P_{c\left(\mathscr{A}_{1}\right)}=0\right\}$. Recall that irreducible variety minus a subvariety is still a connected set. If $\left(\left(x_{1}: y_{1}\right), \ldots,\left(x_{n}: y_{n}\right)\right)=((1: 0), \ldots,(1: 0)) \quad$ (respectively $\quad((0: 1), \ldots,(0: 1))$ then $\mathscr{A}^{*}$ is $\mathscr{A}_{0}^{*}$ (respectively $\mathscr{A}_{1}^{*}$ ). Therefore condition (3.22) is satisfied at these two points, so there is a curve from $((1: 0), \ldots,(1: 0))$ to $((0: 1), \ldots,(0: 1))$ such that (3.2) is satisfied for any point lying in the curve. This means that we have constructed a one-parameter family of arrangements $\mathscr{A}^{*}(t)$ such that $\mathscr{A}^{*}(0)=\mathscr{A}_{0}^{*}, \mathscr{A}^{*}(1)=\mathscr{A}_{1}^{*}$ and $L(\mathscr{A}(t)) \equiv L\left(\mathscr{A}_{0}\right)$ for all $t \in[0,1]$.

We now define a stratification of $\mathbf{C} \mathbf{P}^{2} \times[0,1]$ which consists of three strata $W, X$ and $Y$ only. Let $Y$ be $\left\{(p, t) \in \mathbf{C P}^{2} \times[0,1]: p\right.$ is a point of multiplicity $k \geqslant 2$ in $\left.\mathscr{A}^{*}(t)\right\}, X$ be $\left\{(p, t) \in \mathbf{C P}^{2} \times[0,1]: p\right.$ is a point of multiplicity one in $\left.\mathscr{A}^{*}(t)\right\}$ and $W=\mathbf{C P}^{2} \times[0,1]-\left\{(p, t) \in \mathbf{C P}^{2} \times[0,1]: p\right.$ is a point of $\left.\mathscr{A}^{*}(t)\right\}$. We can think of $X \cup Y$ as a total space of the family of plane curve singularities $\left|\mathscr{A}^{*}(t)\right|$ ( $=$ union of hyperplanes of $\mathscr{A}^{*}(t)$ ) in $\mathbf{C} \mathbf{P}^{2}$. Since $L\left(\mathscr{A}^{*}(t)\right)$ is isomorphic to $L\left(\mathscr{A}_{0}^{*}\right)$ for all $t$, we see easily that this family of plane singularities is a $\mu^{*}$-constant family. In view of a theorem of Teissier [Te], the stratification satisfies the Whitney condition. Consider $\mathbf{C P}^{2} \times[0,1]$ together with the projection map to the second factor. This map is proper since $\mathbf{C P}^{2}$ is compact. It is also a submersion. Moreover its restriction is a submersion on each stratum. Now we apply Thom's first isotopy theorem (proved by Mather [Ma]) to finish the proof of our Main Theorem. For the convenience of the reader, we recall the statement of Thom's first isotopy theorem which can be found for instance in [Go-Mac].

THOM'S FIRST ISOTOPY THEOREM. Let $f: Z \rightarrow \mathbf{R}^{n}$ be a proper, smooth map which is a submersion on each stratum of a Whitney stratification of $Z$. Then there is a stratum-preserving homeomorphism

$$
h: Z \rightarrow \mathbf{R}^{n} \times\left(f^{-1}(0) \cap Z\right)
$$

which is smooth on each stratum and commutes with the projection to $\mathbf{R}^{n}$. In particular, the fibres of $f$ are homeomorphic by a stratum-preserving homeomorphism.

## 4. Examples

In this section, we shall show an example of an arrangement which is not nice, but the statement of our Main Theorem is still true.

EXAMPLE 4.1. Let $G$ be the following graph

$G$ consists of 8 lines and 5 triple points

$$
G^{\prime}=G-\left(E\left(\mathrm{St}\left(V_{0}\right)\right) \cup\left\{V_{0}\right\}\right) .
$$

Clearly $\mathscr{A}^{*}$ is not a nice arrangement. However the proof of our Main Theorem still works if we can show that $((1: 0), \ldots,(1: 0))$ and $((0: 1), \ldots,(0: 1))$ in $\left(\mathbf{C P}^{1}\right)^{8}$ is in the same irreducible component of the following variety defined by the following equations

$$
\begin{align*}
& a_{0} y_{1} y_{2} x_{3}+b_{0} y_{1} x_{2} x_{3}+c_{0} x_{1} y_{2} x_{3}+\alpha_{0} x_{1} x_{2} y_{3}+\beta_{0} x_{1} y_{2} y_{3}+\gamma_{0} y_{1} x_{2} y_{3}=0  \tag{4.1}\\
& a_{1} y_{3} y_{4} x_{5}+b_{1} y_{3} x_{4} x_{5}+c_{1} x_{3} y_{4} x_{5}+\alpha_{1} x_{3} x_{4} y_{5}+\beta_{1} x_{3} y_{4} y_{5}+\gamma_{1} y_{3} x_{4} y_{5}=0  \tag{4.2}\\
& a_{2} y_{2} y_{5} x_{6}+b_{2} y_{2} x_{5} x_{6}+c_{2} x_{2} y_{5} x_{6}+\alpha_{2} x_{2} x_{5} y_{6}+\beta_{2} x_{2} y_{5} y_{6}+\gamma_{2} y_{2} x_{5} y_{6}=0  \tag{4.3}\\
& a_{3} y_{1} y_{6} x_{7}+b_{3} y_{1} x_{6} x_{7}+c_{3} x_{1} y_{6} x_{7}+\alpha_{3} x_{1} x_{6} y_{7}+\beta_{3} x_{1} y_{6} y_{7}+\gamma_{3} y_{1} x_{6} y_{7}=0  \tag{4.4}\\
& a_{4} y_{4} y_{7} x_{8}+b_{4} y_{4} x_{7} x_{8}+c_{4} x_{4} y_{7} x_{8}+\alpha_{4} x_{4} x_{7} y_{8}+\beta_{4} x_{4} y_{7} y_{8}+\gamma_{4} y_{4} x_{7} y_{8}=0 \tag{4.5}
\end{align*}
$$

Let $\left(x_{1}: y_{1}\right),\left(x_{2}: y_{2}\right)$ and $\left(x_{4}: y_{4}\right)$ be regular values of (4.1), $\ldots$, (4.5). Thus we have from (4.1), $\ldots$, (4.5) respectively the following

$$
\begin{align*}
& \left(x_{3}: y_{3}\right)=\left(-\left(\alpha_{0} x_{1} x_{2}+\beta_{0} x_{1} y_{2}+\gamma_{0} y_{1} x_{2}\right):\left(a_{0} y_{1} y_{2}+b_{0} y_{1} x_{2}+c_{0} x_{1} y_{2}\right)\right)  \tag{4.6}\\
& \left(x_{5}: y_{5}\right)=\left(-\left(\alpha_{1} x_{3} x_{4}+\beta_{1} x_{3} y_{4}+\gamma_{1} y_{3} x_{4}\right):\left(a_{1} y_{3} y_{4}+b_{1} y_{3} x_{4}+c_{1} x_{3} y_{4}\right)\right)  \tag{4.7}\\
& \left(x_{6}: y_{6}\right)=\left(-\left(\alpha_{2} x_{2} x_{5}+\beta_{2} x_{2} y_{5}+\gamma_{2} y_{2} x_{5}\right):\left(a_{2} y_{2} y_{5}+b_{2} y_{2} x_{5}+c_{2} x_{2} y_{5}\right)\right)  \tag{4.8}\\
& \left(x_{7}: y_{7}\right)=\left(-\left(\alpha_{3} x_{1} x_{6}+\beta_{3} x_{1} y_{6}+\gamma_{3} y_{1} x_{6}\right):\left(a_{3} y_{1} y_{6}+b_{3} y_{1} x_{6}+c_{3} x_{1} y_{6}\right)\right)  \tag{4.9}\\
& \left(x_{8}: y_{8}\right)=\left(-\left(\alpha_{4} x_{4} x_{7}+\beta_{4} x_{4} y_{7}+\gamma_{4} y_{4} x_{7}\right):\left(a_{4} y_{4} y_{7}+b_{4} y_{4} x_{7}+c_{4} x_{4} y_{y}\right)\right) \tag{4.10}
\end{align*}
$$

Let $V=\left\{\left(\left(x_{1}: y_{1}\right),\left(x_{2}: y_{2}\right),\left(x_{4}: y_{4}\right)\right) \in\left(\mathbf{C} \mathbf{P}^{1}\right)^{3}:\left(x_{1}: y_{1}\right),\left(x_{2}: y_{2}\right)\right.$ and $\left(x_{4}: y_{4}\right)$ are regular of (4.1)-(4.5) $\}$. Since for each $i,\left(x_{i}: y_{i}\right)$ has at most 2 irregular values for each equation. So $V$ is a connected open subset of ( $\left.\mathbf{C P})^{1}\right)^{3}$ by taking away finite number of planes and lines from $\left(\mathbf{C P}^{1}\right)^{3}$. Let $W=\left\{\left(\left(x_{1}: y_{1}\right), \ldots,\left(x_{8}: y_{8}\right)\right) \in\left(\mathbf{C} \mathbf{P}^{1}\right)^{8}:(4.6)-(4.10)\right.$ are satisfied and $\left(\left(x_{1}: y_{1}\right)\right.$, $\left.\left.\left(x_{2}: y_{2}\right),\left(x_{4}: y_{4}\right)\right) \in V\right\}$. Observe that $V$ is homeomorphic to $W$ by the map defined by (4.6)-(4.10). It follows that $W$ is an irreducible variety containing $((0: 1), \ldots,(0: 1))$ and $((1: 0), \ldots,(1: 0)) \in\left(\mathbf{C P}^{1}\right)^{8}$. So the Main Theorem is still true for this arrangement, i.e. $\mathscr{A}^{*}$ is a good arrangement.

REMARK. Each expression of (4.7)-(4.10) can be written in terms of $\left(x_{1}: y_{1}\right)$, $\left(x_{2}: y_{2}\right)$ and $\left(x_{4}: y_{4}\right)$ by successive substitution of each previous expression.

In the next example, we shall associate to a projective arrangement in $\mathbf{C P}{ }^{2}$ two varieties in $\left(\mathbf{C P}^{1}\right)^{6}$. We shall show that these two varieties have 8 irreducible components. In the first variety, $((1: 0), \ldots,(1: 0))$ and $((0: 1), \ldots,(0: 1))$ are in the same irreducible component, while in the second variety $((1: 0), \ldots,(1: 0))$ and $((0: 1), \ldots,(0: 1))$ are in different irreducible components.

EXAMPLE 4.2. Let $\mathscr{A}^{*}$ be a projective arrangement with the following graph $G$.

$G$ consists of 6 lines and 4 triple points

$$
G^{\prime}=G-\left(E\left(\operatorname{St}\left(v_{0}\right) \cup\left\{v_{0}\right\}\right)\right.
$$

$$
\left.\begin{array}{l}
a_{0} y_{1} x_{2} x_{3}+b_{0} x_{1} y_{2} x_{3}+c_{0} x_{1} x_{2} y_{3}+\alpha_{0} x_{1} y_{2} y_{3}+\beta_{0} y_{1} x_{2} y_{3}+\gamma_{0} y_{1} y_{2} x_{3}=0 \\
a_{1} y_{1} x_{4} x_{5}+b_{1} x_{1} y_{4} x_{5}+c_{1} x_{1} x_{4} y_{5}+\alpha_{1} x_{1} y_{4} y_{5}+\beta_{1} y_{1} x_{4} y_{5}+\gamma_{1} y_{1} y_{4} x_{5}=0  \tag{4.1}\\
a_{2} y_{2} x_{5} x_{6}+b_{2} x_{2} y_{5} x_{6}+c_{2} x_{2} x_{5} y_{6}+\alpha_{2} x_{2} y_{5} y_{6}+\beta_{2} y_{2} x_{5} y_{6}+\gamma_{2} y_{2} y_{4} x_{6}=0 \\
a_{3} y_{3} x_{6} x_{4}+b_{3} x_{3} y_{6} x_{4}+c_{3} x_{3} x_{6} y_{4}+\alpha_{3} x_{3} y_{6} y_{4}+\beta_{3} y_{3} x_{6} y_{4}+\gamma_{3} y_{3} y_{6} x_{4}=0
\end{array}\right\}
$$

(I). The simplest example is that we take $a_{i}=b_{i}=c_{i}=\alpha_{i}=\beta_{i}^{i}=\gamma_{i}=1$ ( $i=0,1,2,3$ ) in (4.11).

If $\left(x_{3}: y_{3}\right)$ is irregular of (2), then Lemma 3.5 says that either $\left(x_{1}: y_{1}\right)$ or $\left(x_{2}: y_{2}\right)$ is irregular of (2). Therefore if $\left(x_{1}: y_{1}\right)$ and ( $x_{2}: y_{2}$ ) are regular of (2), so is $\left(x_{3}: y_{3}\right)$. Thus we have

$$
\begin{equation*}
x_{i}^{2}+y_{i}^{2}+x_{i} y_{i} \neq 0 \quad \text { for } i=1,2,3 \tag{4.12}
\end{equation*}
$$

i.e. $\left(x_{i}: y_{i}\right) \neq(\alpha: 1)$ or $(\beta: 1)$ for $i=1,2,3$ where

$$
\alpha=\frac{-1+\sqrt{3} i}{2}, \quad \beta=\frac{-1-\sqrt{3} i}{2}
$$

Observe that $\alpha \beta=1, \alpha+\beta=-1$. Write equation (4.11) as follows

$$
\begin{align*}
\left(x_{3}: y_{3}\right) & =\left(-x_{1} x_{2}-x_{1} y_{2}-y_{1} x_{2}: y_{1} y_{2}+y_{1} x_{2}+x_{1} y_{2}\right) \\
\binom{x_{4}}{y_{4}} & =k_{1} A_{1}\binom{x_{5}}{y_{5}},\binom{x_{5}}{y_{5}}=k_{2} A_{2}\binom{x_{6}}{y_{6}},\binom{x_{6}}{y_{6}}=k_{3} A_{3}\binom{x_{4}}{y_{4}} \tag{4.13}
\end{align*}
$$

where $k_{i} \in \mathbf{C} \backslash\{0\}$ and

$$
A_{i}=\left(\begin{array}{cc}
-\left(x_{i}+y_{i}\right) & -x_{i} \\
y_{i} & x_{i}+y_{i}
\end{array}\right) \quad i=1,2,3 .
$$

Each $\left\|A_{i}\right\| \neq 0$ by (4.12). It follows from (4.13) that

$$
\binom{x_{4}}{y_{4}}=k A\binom{x_{4}}{y_{4}}
$$

where $k$ is some number if $\mathbf{C} \backslash\{0\}$ and

$$
A=\left(x_{1}^{2}+y_{1}^{2}+x_{1} y_{1}\right)\left(\begin{array}{cc}
x_{2}^{2}-y_{2}^{2} & x_{2}^{2}+2 x_{2} y_{2} \\
y_{2}^{2}+2 x_{2} y_{2} & -\left(x_{2}^{2}-y_{2}^{2}\right)
\end{array}\right)
$$

For a solution $\left(x_{4}: y_{4}\right) \in \mathbf{C} \mathbf{P}^{1}$, we must have $\operatorname{det}(k A-I)=0$. So

$$
k= \pm \frac{1}{\Delta} \quad \text { where } \Delta=\left(x_{1}^{2}+y_{1}^{2}+x_{1} y_{1}\right)\left(x_{2}^{2}+y_{2}^{2}+x_{2} y_{2}\right) .
$$

For $k=1 / \Delta$, we have a solution of (4.11)

$$
\left.\begin{array}{l}
\left(x_{4}: y_{4}\right)=\left(x_{2}: y_{2}\right)  \tag{4.14}\\
\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=\left(-x_{1} x_{2}-x_{1} y_{2}-y_{1} x_{2}: y_{1} y_{2}+x_{1} y_{2}+y_{1} x_{2}\right) \\
\left(x_{6}: y_{6}\right)=\left(x_{1}: y_{1}\right)
\end{array}\right\}
$$

It is easy to check that the solution (4.14) of (4.11) is valid for all $\left(\left(x_{1}: y_{1}\right)\right.$, $\left.\left(x_{2}: y_{2}\right)\right) \in\left(\mathbf{C P}^{1}\right)^{2}-\left\{P_{1}, P_{2}\right\}$ where $P_{1}=((\alpha: 1),(\beta: 1))$ and $P_{2}=((\beta: 1),(\alpha: 1))$. This solution set (4.14) is isomorphic to $\left(\mathbf{C P} \mathbf{P}^{1}\right)^{2}-\left\{P_{1}, P_{2}\right\}$. It contains $((0: 1), \ldots,(0: 1))$ and $((1: 0), \ldots,(1: 0))$ of $\left(\mathbf{C P}^{1}\right)^{6}$. We denote this solution set $U_{1}^{\prime}$.

For $k=-1 / \Delta$, we have another solution set of (4.11) denoted by $U_{2}^{\prime}$

$$
\begin{align*}
& \left(x_{3}: y_{3}\right)=\left(-x_{1} x_{2}-x_{1} y_{2}-y_{1} x_{2}: y_{1} y_{2}+y_{1} x_{2}++x_{1} y_{2}\right) \\
& \left(x_{4}: y_{4}\right)=\left(-x_{2}-2 y_{2}: 2 x_{2}+y_{2}\right)  \tag{4.15}\\
& \left(x_{5}: y_{5}\right)=\left(x_{1} x_{2}-x_{1} y_{2}-y_{1} x_{2}-2 y_{1} y_{2}: y_{1} y_{2}-y_{1} x_{2}-x_{1} y_{2}-2 x_{1} x_{2}\right) \\
& \left(x_{6}: y_{6}\right)=\left(-x_{1}-2 y_{1}: 2 x_{1}+y_{1}\right)
\end{align*}
$$

for all $\left(\left(x_{1}: y_{1}\right),\left(x_{2}: y_{2}\right)\right) \in\left(\mathbf{C P}^{1}\right)^{2}-\left\{P_{1}, P_{2}\right\}$.

For $\left(x_{1}: y_{1}\right)$ or $\left(x_{2}: y_{2}\right)$ being fixed as irregular of (4.11) we get all other six solution sets of (2) in ( $\left.\mathbf{C P} \mathbf{P}^{1}\right)^{6}$.

$$
\begin{aligned}
& U_{3}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\alpha: 1),\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\beta: 1)\right\} \\
& U_{4}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\beta: 1),\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\alpha: 1)\right\} \\
& U_{5}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\alpha: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\beta: 1)\right\} \\
& U_{6}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\beta: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\alpha: 1)\right\} \\
& U_{7}=\left\{\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\alpha: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\beta: 1)\right\} \\
& U_{8}=\left\{\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\beta: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\alpha: 1)\right\} .
\end{aligned}
$$

Each of these six sets is isomorphic to $\left(\mathbf{C} \mathbf{P}^{1}\right)^{2}$. So they are irreducible components. Furthermore, if we define

$$
\begin{aligned}
& V_{1}=\left\{\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)\right\} \cap\left(U_{3} \cup U_{4}\right), \\
& V_{2}=\left\{\left(x_{5}: y_{5}\right)=\left(x_{3}: y_{3}\right)\left(\begin{array}{ll}
-1 & 2 \\
-2 & 1
\end{array}\right) \cap\left(U_{3} \cup U_{4}\right)\right\}
\end{aligned}
$$

in $\left(\mathbf{C P}^{1}\right)^{6}$. Let $U_{1}=U_{1}^{\prime} \cup V_{1}$ and $U_{2}=U_{2}^{\prime} \cup V_{2}$. Then both $U_{1}$ and $U_{2}$ are irreducible components of the algebraic set defined by (4.11). For the proof of the last statement we consider $U_{1}^{\prime}$ which is isomorphic to $\left(\mathbf{C} \mathbf{P}^{1}\right)^{2}-\left\{P_{1}, P_{2}\right\}$. Each element of $V_{1}$ is in the closure of $U_{1}^{\prime}$ since

$$
\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=\left(-x_{1} x_{2}-x_{2} y_{1}-x_{1} y_{2}: y_{1} y_{2}+x_{1} y_{2}+y_{1} x_{2}\right)
$$

in $U_{1}^{\prime}$ so $U_{1}$ is an irreducible component defined by the following equations:

$$
\begin{aligned}
& x_{2} y_{4}-y_{2} x_{4}=0 \\
& x_{1} y_{6}-y_{1} x_{6}=0 \\
& x_{3} y_{5}-y_{3} x_{5}=0 \\
& \left(y_{1} y_{2}+x_{1} y_{2}+x_{1} y_{1}\right) x_{3}+\left(x_{1} x_{2}+x_{1} y_{2}+x_{2}^{2} y_{1}\right) y_{3}=0
\end{aligned}
$$

Similarly we can show that $U_{2}$ is also an irreducible component.
The connection among those eight irreducible components can be expressed by the following configurations.

Fig. 4.1.

Figure 4.1(a) and (b) indicates that $U_{1} \cap U_{2}=\left\{R_{1}, R_{2}, \ldots, R_{6}\right\}$ where the six points are as follows:

$$
\begin{aligned}
U_{5} & \cap U_{7}=R_{1} \\
& =\left\{\left(x_{1}: y_{1}\right)=\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=\left(x_{6}: y_{6}\right)=(\alpha: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\beta: 1)\right\} \\
U_{6} & \cap U_{8}=R_{2} \\
& =\left\{\left(x_{1}: y_{1}\right)=\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=\left(x_{6}: y_{6}\right)=(\beta: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\alpha: 1)\right\} \\
U_{3} & \cap U_{5}=R_{3} \\
& =\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\alpha: 1),\left(x_{2}: y_{2}\right)=\left(x_{3}: y_{3}\right)=\left(x_{4}: y_{4}\right)=\left(x_{5}: y_{5}\right)=(\beta: 1)\right\} \\
U_{4} & \cap U_{6}=R_{4} \\
& =\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\beta: 1),\left(x_{2}: y_{2}\right)=\left(x_{3}: y_{3}\right)=\left(x_{4}: y_{4}\right)=\left(x_{5}: y_{5}\right)=(\alpha: 1)\right\} \\
U_{4} & \cap U_{7}=R_{5} \\
& =\left\{\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\alpha: 1),\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\beta: 1)\right\} \\
U_{3} & \cap U_{8}=R_{6} \\
& =\left\{\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\beta: 1),\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\alpha: 1)\right\} .
\end{aligned}
$$

The intersection of $U_{i}(i=1$ or 2$)$ and $U_{j}=(j=3,4,5$ or 6$)$ is a line. We list them as follows:

$$
\begin{aligned}
& U_{1} \cap U_{3}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\alpha: 1),\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\beta: 1),\right. \\
& \left.\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)\right\} \\
& U_{1} \cap U_{4}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\beta: 1),\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\alpha: 1)\right. \text {, } \\
& \left.\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)\right\} \\
& U_{2} \cap U_{3}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\alpha: 1),\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\beta: 1)\right. \text {, } \\
& \left.\left(x_{5}: y_{5}\right)=\left(x_{3}: y_{3}\right)\left(\begin{array}{ll}
-1 & 2 \\
-2 & 1
\end{array}\right)\right\} \\
& U_{2} \cap U_{4}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\beta: 1),\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\alpha: 1)\right. \text {, } \\
& \left.\left(x_{5}: y_{5}\right)=\left(x_{3}: y_{3}\right)\left(\begin{array}{ll}
-1 & 2 \\
-2 & 1
\end{array}\right)\right\} \\
& U_{1} \cap U_{5}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\alpha: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\beta: 1),\right. \\
& \left.\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)\right\} \\
& U_{1} \cap U_{6}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\beta: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\alpha: 1),\right. \\
& \left.\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)\right\} \\
& U_{2} \cap U_{5}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\alpha: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\beta: 1),\right. \\
& \left.\left(x_{4}: y_{4}\right)=\left(x_{2}: y_{2}\right)\left(\begin{array}{ll}
-1 & 2 \\
-2 & 1
\end{array}\right)\right\} \\
& U_{2} \cap U_{6}=\left\{\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)=(\beta: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\alpha: 1)\right. \text {, } \\
& \left.\left(x_{4}: y_{4}\right)=\left(x_{2}: y_{2}\right)\left(\begin{array}{ll}
-1 & 2 \\
-2 & 1
\end{array}\right)\right\} \\
& U_{1} \cap U_{7}=\left\{\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\alpha: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\beta: 1),\right. \\
& \left.\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)\right\} \\
& U_{1} \cap U_{8}=\left\{\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\beta: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\alpha: 1),\right. \\
& \left.\left(x_{1}: y_{1}\right)=\left(x_{6}: y_{6}\right)\right\} \\
& U_{2} \cap U_{7}=\left\{\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\alpha: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\beta: 1)\right. \text {, } \\
& \left.\left(x_{6}: y_{6}\right)=\left(x_{1}: y_{1}\right)\left(\begin{array}{ll}
-2 & 2 \\
-2 & 1
\end{array}\right)\right\}
\end{aligned}
$$

$$
\begin{aligned}
U_{2} \cap U_{8}= & \left\{\left(x_{2}: y_{2}\right)=\left(x_{4}: y_{4}\right)=(\beta: 1),\left(x_{3}: y_{3}\right)=\left(x_{5}: y_{5}\right)=(\alpha: 1)\right. \\
& \left.\left(x_{6}: y_{6}\right)=\left(x_{1}: y_{1}\right)\left(\begin{array}{ll}
-2 & 2 \\
-2 & 1
\end{array}\right)\right\} .
\end{aligned}
$$

(II). The second example is that we take $a_{i}=-3, \beta_{i}=\gamma_{i}=-1$, $b_{i}=c_{i}=\alpha_{i}=1$ for $i=1,2,3$. Then we get the following $P_{r}$ equations in the proof of Theorem 3.3

$$
\begin{aligned}
& P_{1} y_{1} x_{2} x_{3}+x_{1} y_{2} x_{3}+x_{1} x_{2} y_{3}+x_{1} y_{2} y_{3}+y_{1} x_{2} y_{3}+y_{1} y_{2} x_{3}=0 \\
& P_{2}-3 y_{1} x_{4} x_{5}+x_{1} y_{4} y_{5}+x_{1} x_{4} y_{5}+x_{1} y_{4} y_{5}-y_{1} x_{4} y_{5}-y_{1} y_{4} x_{5}=0 \\
& P_{3}-3 y_{2} x_{5} y_{6}+x_{2} y_{5} x_{6}+x_{2} x_{5} y_{6}+x_{2} y_{5} x_{6}-y_{2} x_{5} y_{6}-y_{2} y_{5} x_{6}=0 \\
& P_{4}-3 y_{3} x_{6} x_{4}+x_{3} y_{6} x_{4}+x_{3} x_{6} y_{4}+x_{3} y_{6} x_{4}-y_{3} x_{6} y_{4}-y_{3} y_{6} x_{4}=0 .
\end{aligned}
$$

To keep the same lattice, we want to take away the following varieties defined by the following $Q_{r}$ equations in the proof of Theorem 3.3.

$$
\begin{array}{ll}
Q_{1} \quad & a_{1} x_{1} x_{2} x_{4}+b_{1} y_{1} x_{2} x_{4}+c_{1} x_{1} y_{2} x_{4}+d_{1} x_{1} x_{2} y_{4}+e_{1} x_{1} y_{2} y_{4}+f_{1} y_{1} x_{2} y_{4} \\
& \quad+g_{1} y_{1} y_{2} x_{4}+h_{1} y_{1} y_{2} y_{4}=0 \\
Q_{2} \quad & a_{2} x_{2} x_{3} x_{5}+b_{2} y_{2} x_{3} x_{5}+c_{2} x_{2} y_{3} x_{5}+d_{2} x_{2} x_{3} y_{5}+e_{3} x_{2} y_{3} y_{5}+f_{2} y_{2} x_{3} y_{5} \\
& \quad+g_{2} y_{2} y_{3} x_{5}+h_{2} y_{2} y_{3} y_{5}=0 \\
Q_{3} \quad & a_{3} x_{3} x_{1} x_{6}+b_{3} y_{3} x_{1} x_{6}+c_{3} x_{3} y_{1} x_{6}+d_{3} x_{3} x_{1} y_{6}+e_{3} x_{3} y_{1} y_{6}+f_{3} y_{3} x_{1} y_{6} \\
& \quad+g_{3} y_{3} y_{1} x_{6}+h_{3} y_{3} y_{1} y_{6}=0 .
\end{array}
$$

Similar computations as before shows that the algebraic set

$$
W=\left\{P_{i}=0, i=1,2,3,4\right\}
$$

has eight irreducible components $W_{1}, W_{2}, \ldots, W_{8}$ where each $W_{i}$ is an irreducible component in $\left(\mathbf{C P}^{1}\right)^{6}$ of dimension 2. In fact the equations for $W_{1}$ and $W_{2}$ are given respectively

$$
W_{1}:\left\{\begin{array}{l}
2 x_{1} x_{6}+x_{1} y_{6}+y_{1} x_{6}=0 \\
2 x_{2} x_{4}+x_{2} y_{4}+y_{2} x_{4}=0 \\
2 x_{3} x_{5}+x_{3} y_{5}+y_{3} x_{5}=0 \\
\left(y_{1} y_{2}+x_{1} y_{2}+x_{2} y_{1}\right) x_{3}+\left(x_{1} x_{2}+x_{1} y_{2}+x_{2} y_{1}\right) y_{3}=0
\end{array}\right.
$$

$$
W_{2}:\left\{\begin{array}{l}
x_{1} y_{6}+3 y_{1} x_{6}+2 y_{1} y_{6}=0 \\
x_{2} y_{4}+3 y_{2} x_{4}+2 y_{2} y_{4}=0 \\
x_{3} y_{5}+3 y_{3} x_{5}+3 y_{3} y_{5}=0 \\
\left(y_{1} y_{2}+x_{1} y_{2}+x_{2} y_{2}\right) x_{3}+\left(x_{1} x_{2}+x_{1} y_{2}+x_{2} y_{1}\right) y_{3}=0 .
\end{array}\right.
$$

Clearly $((0: 1), \ldots,(0: 1)) \in W_{1}$ and $\left((1: 0, \ldots,(1: 0)) \in W_{2}\right.$.
We want to show that for some chosen coefficients in equations $Q_{i}$,

$$
W-\bigcup_{i=1}^{3}\left\{Q_{i}=0\right\}
$$

becomes disconnected in such a way that there is no path joining $((1: 0), \ldots,(1: 0))$ and $((0: 1), \ldots,(0: 1))$. We first observe that $W_{1} \cap W_{2}=\left\{R_{1}\right.$, $\left.R_{2}, \ldots, R_{6}\right\}$ where

$$
\begin{aligned}
R_{1}:\left(\left(x_{1}: y_{1}\right)\right. & =\left(x_{2}: y_{2}\right)=(\alpha: 1),\left(x_{3}: y_{3}\right)=(\beta: 1), \\
\left(x_{4}: y_{4}\right) & \left.=\left(x_{6}: y_{6}\right)=(-\alpha: 2 a+1),\left(x_{5}: y_{5}\right)=(-\beta: 2 \beta+1)\right) \\
R_{2}:\left(\left(x_{1}: y_{1}\right)\right. & =\left(x_{2}: y_{2}\right)=(\beta: 1),\left(x_{3}: y_{3}\right)=(\alpha: 1), \\
\left(x_{4}: y_{4}\right) & \left.=\left(x_{6}: y_{6}\right)=(-\beta: 2 \beta+1),\left(x_{5}: y_{5}\right)=(-\alpha: 2 \alpha+1)\right) \\
R_{3}:\left(\left(x_{1}: y_{1}\right)\right. & =(\alpha: 1),\left(x_{6}: y_{6}\right)=(-\alpha: 2 \alpha+1), \\
\left(x_{2}: y_{2}\right) & \left.=\left(x_{3}: y_{3}\right)=(\beta: 1),\left(x_{4}: y_{4}\right)=\left(x_{5}: y_{5}\right)=(-\beta: 2 \beta+1)\right) \\
R_{4}:\left(\left(x_{1}: y_{1}\right)\right. & =(\beta: 1),\left(x_{6}: y_{6}\right)=(-\beta: 2 \beta+1), \\
\left(x_{2}: y_{2}\right) & \left.=\left(x_{3}: y_{3}\right)=(\alpha: 1),\left(x_{4}: y_{4}\right)=\left(x_{5}: y_{5}\right)=(-\alpha: 2 \alpha+1)\right) \\
R_{5}:\left(\left(x_{2}: y_{2}\right)\right. & =(\alpha: 1),\left(x_{4}: y_{4}\right)=(-\alpha: 2 \alpha+1), \\
\left(x_{1}: y_{1}\right) & =\left(x_{3}: y_{3}\right)=(\beta: 1),\left(x_{5}: y_{5}\right)=\left(x_{6}: y_{6}\right)=(-\beta: 2 \beta+1) \\
R_{6}:\left(\left(x_{2}: y_{2}\right)\right. & =(\beta: 1),\left(x_{4}: y_{4}\right)=(-\beta: 2 \beta+1), \\
\left(x_{1}: y_{1}\right) & \left.=\left(x_{3}: y_{3}\right)=(\alpha: 1),\left(x_{5}: y_{5}\right)=\left(x_{6}: y_{6}\right)=(-\alpha: 2 \alpha+1)\right) .
\end{aligned}
$$

Let us take $a_{i}=2, b_{i}=1, c_{i}=1, d_{i}=1, e_{i}=0, g_{i}=2, h_{i}=1$ in equations $Q_{1}$, $Q_{2}$, and $Q_{3}$. Then

$$
\begin{aligned}
& \left\{Q_{1}=0\right\} \supseteq\left(W_{1} \cap W_{3}\right) \cup\left(W_{1} \cap W_{4}\right) \cup\left(W_{2} \cap W_{3}\right) \cup\left(W_{2} \cap W_{4}\right) \\
& \left\{Q_{2}=0\right\} \supseteq\left(W_{1} \cap W_{7}\right) \cup\left(W_{1} \cup W_{8}\right) \cup\left(W_{2} \cap W_{7}\right) \cup\left(W_{2} \cap W_{8}\right) \\
& \left\{Q_{3}=0\right\} \supseteq\left(W_{1} \cap W_{5}\right) \cup\left(W_{1} \cap W_{6}\right) \cup\left(W_{2} \cap W_{5}\right) \cup\left(W_{2} \cap W_{6}\right) .
\end{aligned}
$$

So $\left\{R_{1}, \ldots, R_{6}\right\} \subseteq \bigcup_{i=1}^{3}\left\{Q_{i}=0\right\}$. The method in Theorem 3.3 does not provide an affirmative answer. However we do not know whether the coefficients so chosen can actually be realized in geometric situation.

In a forthcoming paper, we shall show that the diffeomorphic type of $M\left(\mathscr{A}^{*}\right)$ indeed depends only on the lattice $L(\mathscr{A})$ for a general class of $\mathscr{A}$ which includes Example 4.2 as a special case.
