Evolution Of Semilinear Conormal Waves

ANTÔNIO SÁ BARRETO

1 Introduction

Let $\Omega \subset \mathbf{R}^3$ be an open subset and let P be a second order strictly hyperbolic differential operator in Ω with smooth coefficients. Let $t \in C^\infty(\Omega)$ be a time function for P and define

$$\Omega^\pm = \Omega \cap \{\pm t > 0\}. \quad (1.1)$$

Assume that Ω is a domain of dependence of Ω^- . Let f be a smooth function of its arguments and suppose $u, Du \in L_{loc}^\infty(\Omega)$ satisfies

$$Pu = f(z, u, Du); \quad z \in \Omega. \quad (1.2)$$

The general question on propagation of singularities of solutions of (1.1) is how do singularities of u in Ω^- influence singularities of u in Ω . We shall concentrate in the study of some geometric singularities called conormal and the first example is conormality to a smooth hypersurface. Thus let $S \subset \Omega$ be a smooth hypersurface which is characteristic for P , let \mathcal{V}_S be the Lie algebra of smooth vector fields tangent to S and denote

$$I_k L_{loc}^2(\Omega, \mathcal{V}_S) = \{u \in L_{loc}^2(\Omega) : \mathcal{V}_S^j u \in L_{loc}^2(\Omega), \quad j \leq k\}. \quad (1.3)$$

Observe that if $u \in I_\infty L_c^2(\Omega, \mathcal{V}_S)$, then u is smooth away from S . In fact one can easily show that in this case the wavefront set of u is contained in the conormal bundle to S .

Theorem 1.1 (Bony, [4]) *Let $u, Du \in H_{loc}^s(\Omega)$, $s > \frac{3}{2}$, satisfy (1.2). If $u, Du \in I_k L_{loc}^2(\Omega^-, \mathcal{V}_S)$, then $u, Du \in I_k L_{loc}^2(\Omega, \mathcal{V}_S)$.*

This result shows that as long as S is smooth u remains conormal to it, but in general characteristic hypersurfaces of P can have rather complicated singularities. In this talk we shall describe the results of [16] and [17] concerning the propagation of conormal singularities for solutions of (1.2) along a hypersurface Σ with either a cusp or a swallowtail singularity. These are in some sense, see [2], the only cases where the singularities are stable under small perturbations. These problems have been also studied by M. Beals [3] and R. Melrose [9], in the case of the cusp and G. Lebeau, [6], [7] and J-M.

Delort [5] in the case of the swallowtail with the hypotheses that P has real analytic coefficients and the regular part of Σ is real analytic.

Before stating our results we have to introduce some notation. Let \mathcal{W} be a Lie algebra and C^∞ module of smooth vector fields on a manifold with corners X and let μ be a smooth measure on X . The space of iteratively regular distributions with respect to \mathcal{W} is then defined as

$$I_k L_{\mu,c}^2(X, \mathcal{W}) = \{u \in L_{\mu,c}^2(X); \mathcal{W}^j u \in L_{\mu,c}^2(X), j \leq k\}. \quad (1.4)$$

2 The Cusp

Let G be a hypersurface with a cusp singularity at a line L , i.e there are local coordinates near $q \in L$ such that

$$G = \{(x, y, z) \in \Omega : y^3 = x^2\}, \quad L = \{(x, y, z) : x = y = 0\}. \quad (2.1)$$

Assume that the smooth part of G is characteristic for P . Let \mathcal{V}_G be Lie algebra of smooth vector fields tangent to G . It is easy to show that the Lie algebra \mathcal{V}_G is characteristic complete, i.e

$$[P, \mathcal{V}_G] \subset \Psi^0(\Omega) \cdot P + \Psi^1(\Omega) \cdot \mathcal{V}_G + \Psi^1(\Omega). \quad (2.2)$$

Where $\Psi^j(\Omega)$ denotes the space of properly supported pseudodifferential operators of order j in Ω . Then by commutator methods, see [4], one obtains **Theorem 2.1** *Let $u, Du \in H_{loc}^s(\Omega)$, $s > \frac{3}{2}$, satisfy equation (1.2). If $u, Du \in I_k L_{loc}^2(\Omega^-, \mathcal{V}_G)$, then $u, Du \in I_k L_{loc}^2(\Omega, \mathcal{V}_G)$.*

Next we recall the spaces of marked Lagrangian distributions introduced by R. Melrose in [9]. Let $\Lambda_G = \text{clos}[N^*(G \setminus L)]$, Λ_G is a smooth conic Lagrangian submanifold of $T^*\mathbb{R}^3$. Let $\Lambda_L = N^*L$ and

$$\mathcal{M}_1(G) = \{A \in \Psi^1(\Omega) : a = \sigma_1(A) = 0 \text{ at } \Lambda_G, \quad (2.3)$$

$$H_a \text{ is tangent to } \Lambda_G \cap \Lambda_L\}.$$

$$\mathcal{M}_1(L) = \{A \in \Psi^1(\Omega) : a = \sigma_1(A) = 0 \text{ at } \Lambda_L, \quad (2.4)$$

$$H_a \text{ is tangent to } \Lambda_G \cap \Lambda_L\}.$$

Let

$$J_k^{G,m}(\Omega) = I_k L_{loc}^2(\Omega, \mathcal{M}_1(G)) + I_k L_{loc}^2(\Omega, \mathcal{M}_1(L)). \quad (2.5)$$

In [9] Melrose proves that

$$J_k^{G,m} \not\subset I_k L_{loc}^2(\Omega, \mathcal{V}_G) \quad (2.6)$$

and

Theorem 2.2 (Melrose, [9]) *Let $u, Du \in H_{loc}^s(\Omega)$, $s > \frac{3}{2}$, satisfy equation (1.2). If $u, Du \in J_k^{G,m}(\Omega^-)$, then $u, Du \in J_k^{G,m}(\Omega)$.*

Finally we introduce a third space of distributions associated to the cusp. Observe that in local coordinates where (2.1) holds one finds that G is invariant under the \mathbf{R}^+ action

$$m_s^{3-2}(x, y) = (s^3x, s^2y). \quad (2.7)$$

This leads to the definition quasi-homogeneous polar coordinates, thus consider the non-round circle

$$S_{3-2}^1 = \{(\omega_1, \omega_2) \in \mathbf{R}^2 : \omega_1^4 + \omega_2^6 = 1\} \quad (2.8)$$

and the manifold with boundary

$$X_{3-2} = S_{3-2}^1 \times [0, \infty) \times \mathbf{R}. \quad (2.9)$$

Then define the blow-down map

$$\beta_{3-2} : X_{3-2} \longrightarrow \mathbf{R}^3, \quad \beta_{3-2}(\omega, r, z) = (r^3\omega_1, r^2\omega_2, z). \quad (2.10)$$

Let \mathcal{W}_G be the Lie algebra of smooth vector fields in X_{3-2} which are tangent to ∂X_{3-2} and to $G^{(1)} = \text{clos} \beta_{3-2}^{-1}[G \setminus L]$. Let μ be the pull back of the Lebesgue measure by the map β_{3-2} . Then one defines

$$J_k^G(\Omega) = \{u \in L_{loc}^2(\Omega) : \beta_{3-2}^* u \in I_k L_c^2(X_{3-2}, \mathcal{W}_G)\}. \quad (2.11)$$

One can easily show that the space $J_k^G(\Omega)$ does not depend on the choice of coordinates such that (2.1) holds. Then see [16], one can show that if \mathcal{W}_G^1 is the Lie algebra of smooth vector fields in X_{3-2} that are tangent to ∂X_{3-2} to $G^{(1)}$ and to the lines $\{\omega_1 = 0, r = 0\}$, $\{\omega_2 = 0, r = 0\}$, then the blow down map β_{3-2} induces an isomorphism

$$\beta_{3-2}^* : J_k^{G,m}(\Omega) \leftrightarrow I_k L_c^2(X_{3-2}, \mathcal{W}_G^1). \quad (2.12)$$

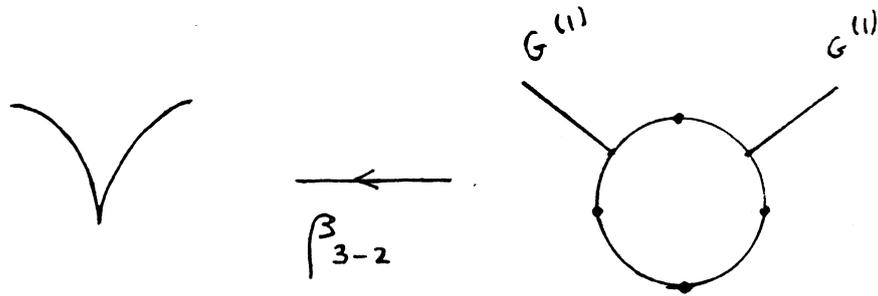

Similarly if \mathcal{W}_G^0 is the Lie algebra of smooth vector fields that are tangent to $G^{(1)}$ and vanish on ∂X_{3-2} , then

$$\beta_{3-2}^* : I_k L_c^2(\Omega, \mathcal{V}_G) \leftrightarrow I_k L_c^2(X_{3-2}, \mathcal{W}_G^0). \quad (2.13)$$

In particular one obtains from (2.12) and (2.13) that

$$J_k^G(\Omega) \not\subset J_k^{G,m} \not\subset I_k L_{loc}^2(\Omega, \mathcal{V}_G). \quad (2.14)$$

Figure 1:

The main difficulty in proving a propagation theorem for $J_k^G(\Omega)$ is that this space is not known to have a microlocal characterization. One of the main results of [16] is the following elliptic regularity type of theorem

Theorem 2.3 *If $u, Du \in H_{loc}^s(\Omega) \cap I_k L_{loc}^2(\Omega, G)$ satisfies equation (1.2), then $u, Du \in J_k^G(\Omega)$.*

Theorem 2.3 illustrates an important idea that will be used in the proof of Theorem 7.1. One first proves a propagation theorem for a bigger space which has a microlocal characterization and then uses the equation to show that the solution is actually in the smaller space.

3 The Swallowtail

Since the results we wish to prove are local we shall assume that $\Omega \subset \mathbb{R}^3$ is a sufficiently small neighborhood of $O = (0, 0, 0)$. Let $\Sigma \subset \Omega$ be a hypersurface with a swallowtail singularity at $O \in \Omega$, i.e there are smooth coordinates (x, y, z) in Ω such that

$$\Sigma = \{(x, y, z) : \delta(\lambda) = \lambda^4 + z\lambda^2 + y\lambda + x = 0, \quad (3.1)$$

has a double real root\}.

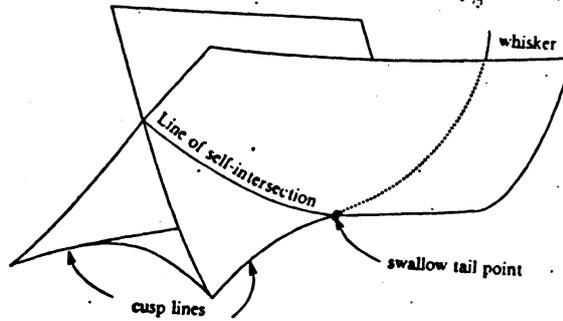

Σ has a cusp singularity at

$$L = \{(x, y, z) : x = -\frac{z^2}{12}, y^2 = (-\frac{2}{3}z)^3\} \quad (3.2)$$

and a self-intersection at

$$H = \{(x, y, z) : y = 0, x = -\frac{z^2}{4}, z \leq 0\}. \quad (3.3)$$

Fig 2:

The continuation of the line H to values of $z > 0$ corresponds to the set of (x, y, z) such that $\delta(\lambda)$ has two double complex roots and therefore is not included in Σ . Let $\Sigma_{\text{reg}} = \Sigma \setminus [L \cup H]$ be the regular part of Σ .

The discriminant of the polynomial $\delta(\lambda)$ is given by

$$\Psi(x, y, z) = 16xz^4 - 4y^2z^3 - 128x^2z^2 + 144xyz^2 + 256x^3 - 27y^4. \quad (3.4)$$

Hence one deduces from (3.2) and (3.3) that

$$\Sigma_{\text{reg}} = \{(x, y, z) : \Psi(x, y, z) = 0, y \neq 0, x \neq \frac{z^2}{12}\}. \quad (3.5)$$

Assume that Σ_{reg} is characteristic for P , i.e if $p = \sigma^2(P)$ is its principal symbol,

$$p(d\Psi) = 0 \text{ at } \Sigma_{\text{reg}}. \quad (3.6)$$

Assume that $t(O) = 0$ and that

$$\Sigma^- = \Sigma \cap \Omega^- \quad (3.7)$$

is a smooth hypersurface of Ω^- .

Let Q be the light cone for P over O , then, see Proposition 3.3, $Q \cap \Sigma = E \cup B$, where away from O , Σ and Q intersect transversally at E and are tangent to third order along B . Let $\mathcal{V}(\Sigma)$ and $\mathcal{V}(\Sigma, Q)$ be the Lie algebras of smooth vector fields tangent to Σ and to Σ and Q respectively.

The following is then a simple consequence of the results of [17].

Theorem 3.1 *Let $u, Du \in H_{loc}^s(\Omega)$, $s > \frac{3}{2}$, satisfy (1.2). If $u, Du \in I_k L_{loc}^2(\Omega^-, \mathcal{V}(\Sigma, Q))$, then $u, Du \in I_k L_{loc}^2(\Omega, \mathcal{V}(\Sigma, Q))$.*

One deduces from Theorem 3.1

Theorem 3.2 *Let $u, Du \in H_{loc}^s(\Omega)$, $s > \frac{3}{2}$, satisfy (1.2). If $u, Du \in I_k L_{loc}^2(\Omega^-, \mathcal{V}(\Sigma))$, then $u, Du \in I_k L_{loc}^2(\Omega, \mathcal{V}(\Sigma, Q))$.*

In fact the results of [17] are stronger, we show that under the hypotheses of Theorem 3.1 the solution is strongly conormal in the sense of Melrose and Ritter, [12], along B and in the sense of [16] along the cusp line L of Σ .

In this note we shall restrict ourselves to the case where u satisfies the weakly semilinear equation

$$Pu = f(z, u), \quad z \in \Omega. \quad (3.8)$$

Since it contains all new ideas involved in the proof of Theorem 3.1

I would like to acknowledge that the main new ideas in [17], originated in joint works (in progress) with R.B. Melrose, [13], and with R.B. Melrose and M. Zworski, [14]. I would like to thank them for sharing their ideas with me, for their interest and encouragement. Possible errors in this manuscript are of course my own fault.

4 Outline Of The Proof

To prove Theorem 3.1 in the case of the weakly semilinear equation (3.6) we shall introduce a family of spaces $J_k(\Omega) \subset I_k L_{loc}^2(\Omega, \mathcal{V}(\Sigma))$, $k \in \mathbf{N}_0$, satisfying the following properties:

- 1) $J_{k+1}(\Omega) \subset J_k(\Omega) \subset L_{loc}^2(\Omega)$, $J_0(\Omega) = L_{loc}^2(\Omega)$.
- 2) $J_k(\Omega)$ is a $C^\infty(\Omega)$ -module.
- 3) $J_k(\Omega) \cap L_{loc}^\infty(\Omega)$ is a C^∞ algebra.
- 4) $u, Du \in J_k(\Omega) \implies u \in J_{k+1}(\Omega)$.
- 5) $Pu = f \in J_k(\Omega)$, $u = f = 0$ in $\Omega_T = \Omega \cap \{t < T\}$, then $u, Du \in J_k(\Omega)$.
- 6) If $u, Du \in I_k L_{loc}^2(\Omega^-, \mathcal{V}(\Sigma))$ in Ω^- satisfy (3.8), then $u, Du \in J_k(\Omega^-)$.

Proof of Theorem 3.1 : Suppose that such a family of spaces $J_k(\Omega)$ has been constructed. We then proceed by an induction argument. Let $\chi \in C^\infty(\mathbf{R})$, $\chi(s) = 0$, $s < -\frac{1}{2}$, $\chi(s) = 1$, $s > 0$. We obtain from (1.8)

$$P\chi u = \chi f(z, u) + [P, \chi]u. \quad (4.1)$$

If $u, Du \in J_0(\Omega) \cap J_1(\Omega^-)$, it follows from properties 2, 3 and 4 that the right hand side of (4.1) is in $J_1(\Omega)$. Thus one deduces from property 5 that $u, Du \in J_1(\Omega)$. By the same argument it follows that if $u, Du \in J_\ell(\Omega) \cap J_{\ell+1}(\Omega^-)$, $\ell < k$, then $u, Du \in J_{\ell+1}(\Omega)$. \square

To define the spaces $J_k(\Omega)$ we shall introduce a blow-down map

$$\beta : X \longrightarrow \mathbf{R}^3 \quad (4.2)$$

from a manifold with corners X to \mathbf{R}^3 such that the lifts of Σ and Q by β intersect each other and the boundary of X transversally. We then define

$$J_k(\Omega) = \{u \in L^2_{loc}(\Omega) : \mathcal{W}^j \beta^* u \in L^2_\mu(X), \quad j \leq k\}. \quad (4.3)$$

Where \mathcal{W} is a Lie algebra and $C^\infty(X)$ module of smooth vector fields in X and μ is the lift of the Lebesgue measure of \mathbf{R}^3 under β . It will be a clear consequence of the definition of X and \mathcal{W} that $J_k(\Omega)$, defined by (4.3), satisfies properties 1,2 and 4. It is a simple consequence of the Gagliardo-Nirenberg type of estimates of [11] that the spaces defined by (4.3) also satisfy property 3. Property 6 follows from Theorem 2.3 and from the results of [15]. The proof of property 5 is of course the most difficult one. The manifold with corners X and the algebra \mathcal{W} will be constructed in Section 6.

5 Model Case

An easy computation shows that, in coordinates where (3.3) holds, Σ is invariant under the \mathbf{R}^+ action

$$m_s^{4-3-2}(x, y, z, t) = (s^4 x, s^3 y, s^2 z, t), \quad s \in \mathbf{R}^+. \quad (5.1)$$

$$\text{Let } M_r^{4-3-2}(\Omega) = \{u \in C^\infty(\Omega) : \partial_x^a \partial_y^b \partial_z^c u(0, 0, 0, t) = 0, \quad (5.2) \\ \forall a, b, c \in \mathbf{N}, \quad 4a + 3b + 2c \leq r\}$$

be the ideal of smooth functions having Taylor series at

$$O = \{(x, y, z, t) \in \Omega; \quad x = y = z = 0\}$$

consisting of terms of homogeneity r or greater with respect to (5.1). A differential operator P is said to have only terms of homogeneity r' or greater, with respect to (5.1), if

$$P : M_r^{4-3-2}(\Omega) \rightarrow M_{r+r'}^{4-3-2}(\Omega), \quad r \in \mathbf{N}_0, \quad r + r' \geq 0. \quad (5.3)$$

Simple computations show that if $P_0 = D_y^2 - D_x D_z$, then Σ_{reg} is characteristic for P_0 , in general one can prove, see [17] that

Proposition 5.1 *If P and Σ are as above and (x, y, z, t) are smooth coordinates in which (3.3) holds, then*

$$P = a(D_y^2 - D_x D_z) + P_{-5}, \quad a \in C^\infty(\Omega), \quad |a| > 0. \quad (5.4)$$

where P_{-5} has only terms of homogeneity -5 or greater with respect to (5.1).

Let Q_0 be the light cone for P_0 over O , then one easily finds that

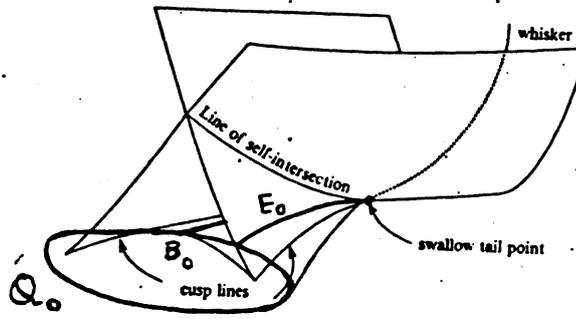

$$Q_0 = \{(x, y, z) \in \Omega : y^2 - 4xz = 0\}. \quad (5.5)$$

In this model we find that away from O , Q_0 and Σ are tangent to third order along B_0 and intersect transversally along E_0 , where

$$B_0 = \{(x, y, z) \in \Omega : x = y = 0\}, \quad (5.6)$$

$$E_0 = \{(x, y, z) \in \Omega : x = \frac{3}{16}z^2, y^2 = -\frac{27}{32}z^3\}. \quad (5.7)$$

Fig 3:

As an immediate consequence of Proposition 5.1 one obtains

Proposition 5.2 *In the local coordinates of Proposition 5.1 one finds that*

$$Q = \{(x, y, z, t) \in \Omega; q(x, y, z, t) = 0\}, \quad (5.8)$$

where

$$q = q_0 + q', \quad q_0 = y^2 - 4xz, \quad q' \in M_7^{4-3-2}(\Omega). \quad (5.9)$$

See [17] for a proof. Now we deduce from it more information about the interaction of Q and Σ .

Proposition 5.3 *With P and Σ as in Proposition 5.1, in a small neighborhood of O , there are smooth functions $F_i(z, t)$, $1 \leq i \leq 3$, such that $Q \cap \Sigma = B \cup E$*

$$B = \{x = z^3 F_1(z, t), y = z^2 F_2(z, t)\}, \quad (5.10)$$

$$E = \{x = \frac{3}{16}z^2 + z^3 F_3(z, t), y^2 = -\frac{27}{32}z^3 + z^4 F_4(z, t)\} \quad (5.11)$$

Away from O , Q and G meet transversally at E and are tangent of third order at B .

6 Geometric Resolution

The hypersurfaces Σ and Q will be resolved to normal crossing by iterated quasi-homogeneous blow ups. As a first step we define the 4-3-2 blow up of \mathbf{R}^n along $O = (0, 0, 0)$.

In \mathbf{R}^3 consider the non-round sphere

$$S_{4-3-2}^2 = \{(\omega_1, \omega_2, \omega_3); \omega_1^6 + \omega_2^8 + \omega_3^{12} = 1\}$$

and the map

$$\beta_1 : X_1 = [0, \infty) \times S_{4-3-2}^2 \longrightarrow \mathbf{R}^3, \quad \beta_1(s, \omega) = (s^4 \omega_1, s^3 \omega_2, s^2 \omega_3).$$

This is surjective and restricts to a diffeomorphism of $X_1 \setminus \partial X_1$ onto $\mathbf{R}^n \setminus K$. Moreover the \mathbf{R}^+ action (5.1) lifts to the standard multiplicative action on the factor $[0, \infty)$.

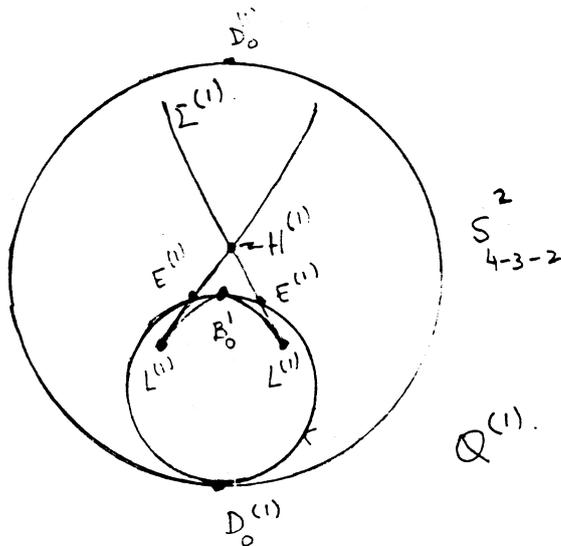

From these observations above it follows that the lifts of the hypersurfaces and the bicharacteristic B in the model case are:

$$\begin{aligned} \Sigma^{(1)} &= \text{clos}[\beta_1^{-1}(\Sigma \setminus O)] = & (6.1) \\ \{16\omega_1\omega_3^4 - 4\omega_2^2\omega_3^3 - 128\omega_1^2\omega_3^2 + 144\omega_1\omega_3\omega_2^2 + 256\omega_1^3 - 27\omega_2^2 = 0\}, \end{aligned}$$

$$Q_0^{(1)} = \text{clos}[\beta_1^{-1}(Q_0 \setminus O)] = \{\omega_2^2 - 4\omega_1\omega_3 = 0\}, \quad (6.2)$$

$$B_0^{(1)} = \text{clos}[\beta_1^{-1}(B \setminus O)] = \{\omega_1 = 0, \omega_2 = 0\}. \quad (6.3)$$

Fig 4:

$\Sigma^{(1)}$ has a cusp singularity at

$$L^{(1)} = \text{clos}[\beta_1^{-1}(L \setminus O)] = \{\omega_1 = -\frac{1}{12}\omega_3^2, \omega_2^2 = (-\frac{2}{3}\omega_3)^3\} \quad (6.4)$$

and a self-intersection at

$$H^{(1)} = \text{clos}[\beta_1^{-1}(L \setminus O)] = \{\omega_1 = -\frac{1}{4}\omega_3^2, \omega_2 = 0\}. \quad (6.5)$$

For reasons that will become clear later on, there are two “great circles” on S_{3-2-1}^2 that will have to be taken into consideration. We define

$$C_1 = \{\omega_1 = 0, r = 0\}, \quad (6.6)$$

$$C_2 = \{\omega_3 = 0, r = 0\}. \quad (6.7)$$

More generally we find, see [17]

Proposition 6.1 *In local coordinates in which (3.1) and (5.8) hold the lifts $\Sigma^{(1)}, Q^{(1)}$ and $B^{(1)}$ of the hypersurfaces and the bicharacteristic to X_1 are diffeomorphic, on X_1 , to the model $\Sigma^{(1)}, Q_0^{(1)}$ and $B^{(1)}$ under a diffeomorphism fixing ∂X_1 pointwise. Conversely any diffeomorphism preserving (3.1), (5.8) and O , lifts to a diffeomorphism of X_1 near ∂X_1 preserving $\Sigma^{(1)}$ and $Q^{(1)}$*

The full resolution of the geometry is obtained by blow ups of the three (really six) submanifolds $L^{(1)}, D_0^{(1)} = Q^{(1)} \cap C_2$ and $B^{(1)}$. There are local coordinates (s, X, Y, T) near $L^{(1)}$ with

$$\Sigma^{(1)} = \{Y^3 = X^2\}, \quad (6.8)$$

near $D_0^{(1)}$ with

$$Q^{(1)} = \{X = Y^2\}, C_2 = \{X = 0, r = 0\}. \quad (6.9)$$

near $B^{(1)}$ with

$$Q^{(2)} = \{X = 0\}, \Sigma^{(1)} = \{X = Y^4\}, C_1 = \{X = Y^2, r = 0\}. \quad (6.10)$$

Thus $\Sigma^{(1)}$ can be resolved to normal crossing by a 3 – 2 blow-up of $L^{(1)}$, thus set

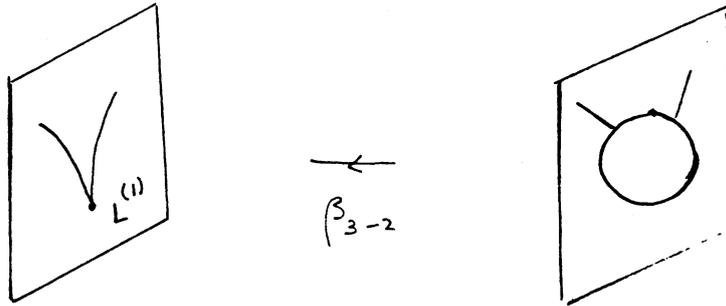

$$S_{3-2}^1 = \{(\theta_1, \theta_2) \in \mathbf{R}^2; \theta_1^4 + \theta_2^6 = 1\} \quad (6.11)$$

and in local coordinates (6.8) we construct the map

$$\beta_{3-2} : [0, \infty)_s \times [0, \infty)_r \times S_{3-2}^1 \times \mathbf{R}^{n-3} \rightarrow X_1 \quad (6.12)$$

$$\beta_{3-2}(s, r, \theta) = (r, s^3\theta_1, s^2\theta_2). \quad (6.13)$$

Fig 5:

It will also be necessary to blow-up $D_0^{(1)}$ with homogeneity 2-1-1, thus let

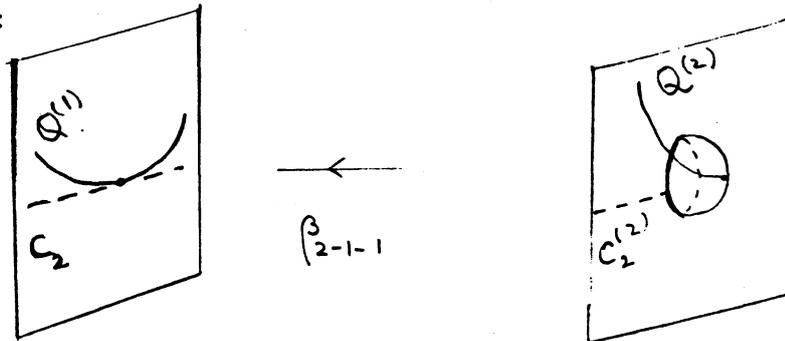

$$S_{2-1-1}^2 = \{(\theta_1, \theta_2, \theta_3) \in \mathbf{R}^2; \theta_1^2 + \theta_2^4 + \theta_3^4 = 1\} \quad (6.14)$$

and in local coordinates (6.9) construct the map

$$\beta_{2-1-1} : [0, \infty)_s \times [0, \infty)_R \times S_{2-1-1}^1 \times \mathbf{R}^{n-3} \rightarrow X_1 \quad (6.15)$$

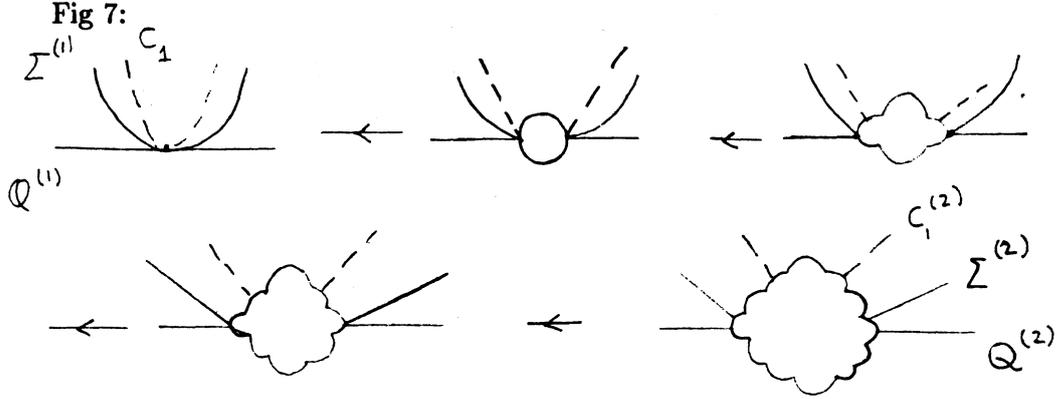

$$\beta_{2-1-1}(s, R, \omega, t) = (R, s^2\theta_1, s\theta_2, s\theta_3, t). \quad (6.16)$$

Fig 6:

To resolve $Q^{(1)}$, $\Sigma^{(1)}$ and C_1 to normal crossing it will be more convenient to use four normal blow-ups as in [12]. Since $Q^{(1)}$ and $\Sigma^{(1)}$ are tangent to third order at $B^{(1)}$, if C_1 did not have to be taken into consideration, one could use a 4-1 nonhomogeneous blow-up to resolve $Q^{(1)}$ and $\Sigma^{(1)}$ to normal

crossing, but C_1 destroys the 4-1 homogeneity.

Since $D_0^1, L^{(1)}$ and $B^{(1)}$ are disjoint we can use these maps to replace small neighborhoods of $D_0^{(1)}, L^{(1)}, B^{(1)}$ by their respective blow ups and so define the manifold with corners X and a blow down map $\beta_2 : X \rightarrow X_1$. Let

$$\beta = \beta_2 \circ \beta_1 : X \rightarrow \mathbf{R}^n \quad (6.17)$$

Denote

$$Q^{(2)} = \text{clos}[\beta_2^{-1}(Q^{(1)} \setminus (B^{(1)} \sqcup D_0^{(1)}))],$$

$$\Sigma^{(2)} = \text{clos}[\beta_2^{-1}(\Sigma^{(1)} \setminus (L^{(1)} \sqcup B^{(1)}))]$$

$$L^{(2)} = \text{clos}[\beta_2^{-1}(L^{(1)})],$$

$$B^{(2)} = \text{clos}[\beta_2^{-1}(B^{(1)})],$$

$$C_1^{(2)} = \text{clos}[\beta_2^{-1}(C_1 \setminus B^{(1)})],$$

$$C_2^{(2)} = \text{clos}[C_2 \setminus D_0^{(1)}].$$

The circle $C_2^{(2)}$ does not continue into the boundary face introduced by the 2-1-1 blow-up.

The manifold with corners X has twelve boundary hypersurfaces which meet transversally pairs or triples. Let $\rho_L, \rho_B^j, 1 \leq j \leq 8, \rho_D$ and ρ_K be respectively the defining functions of $\beta^{-1}(L)$, each of the eight hypersurfaces of $\beta^{-1}(B), \beta^{-1}(D)$ and $\beta^{-1}(K)$ (These functions are assumed to be extended smoothly past the surfaces they define).

Proposition 6.2 Under the C^∞ map $\beta : X \rightarrow \mathbf{R}^n$ the lifts

$$\beta^*(M) = \text{clos}[\beta^{-1}(M \setminus [K \cup L \cup B])], \quad (6.18)$$

for $M = Q, \Sigma$ are smooth hypersurfaces that intersect the boundaries of X transversally. Any C^∞ diffeomorphism of X_1 preserving $\Sigma^{(1)}, Q^{(1)}, D_0^{(1)}$ and ∂X_1 lifts to a C^∞ diffeomorphism of X preserving all boundaries and all the hypersurfaces.

Let $L_c^2(X)$ be the space of compactly supported square integrable functions in X with respect to the measure $\mu = \beta^*(dx dy dz)$. Then the blow down map β gives an isomorphism

$$\beta^* : L_c(\mathbf{R}^n) \leftrightarrow L_c^2(X). \quad (6.19)$$

Let \mathcal{W} be the Lie algebra and smooth vector fields W on X satisfying the following properties:

- 1) W is tangent to all boundary hypersurfaces.
- 2) W is tangent to $\beta^*(\Sigma)$ and to $\beta^*(Q)$.
- 3) W is tangent to $C_2^{(2)}$.
- 4) In local coordinates (r, s, X) in which $\rho_K = r$ and $C_1^{(2)} = \{r = X = 0\}$, \mathcal{W} is spanned by $r\partial_r, s\partial_s, X\partial_X, r^2\partial_X$.

We then define for any integer k

$$J_k(\Omega) = \{u \in L_c^2(\Omega) : \beta^*u \in I_k L_c^2(X, \mathcal{W})\} \quad (6.20)$$

As a consequence of Propositions 6.1 and 6.2 it follows that the spaces $J_k(\Omega)$ are independent on the choices of coordinates. Moreover from the Gagliardo-Nirenberg type inequalities of [15] one obtains

Proposition 6.3 For any $k \in \mathbf{N}$, $J_k(\Omega) \cap L_{loc}^\infty(\Omega)$ is a C^∞ algebra, i.e for any $f \in C^\infty(\mathbf{R}^m)$ and $u_i \in J_k(\Omega) \cap L^\infty(\Omega), 1 \leq i \leq m$,

$$f(u_1, \dots, u_m) \in J_k(\Omega) \cap L_{loc}^\infty(\Omega). \quad (6.21)$$

By writing the generators of $\mathcal{V}(\Sigma, Q)$ and their lift under the map β it is not hard to see that

$$J_k(\Omega) \subset I_k L_{loc}^2(\Omega, \mathcal{V}(\Sigma, Q)) \quad (6.22)$$

7 The Linear Propagation Theorem

In this section we sketch the proof that the spaces $J_k(\Omega)$ satisfy
Theorem 7.1 *Let $f \in J_k(\Omega)$, $f = 0$ in Ω^- . Let $u \in H_{loc}^1(\Omega)$, $u = 0$ in Ω^- , satisfy*

$$Pu = f. \quad (7.1)$$

Then $u, Du \in J_k(\Omega)$.

Lemma 7.1 *Let $\phi \in C_0^\infty(X_1)$, $\phi = 1$ in sufficiently small neighborhoods of $L^{(1)}$, $E^{(1)}$ and $H^{(1)}$, $\phi = 0$ outside slightly bigger neighborhoods. There exist $v_1, Dv_1 \in J_k(\Omega)$ such that*

$$\beta_1^*(Pv_1) - \phi\beta_1^*f \in I_k L_{loc}^2(X_1, \partial X_1) \quad (7.2)$$

The proof of Lemma 7.1 is based on the fact that the lift of the operator P by the map β_1 is of real principal type in the totally characteristic sense, see [10], in some directions near $L^{(1)}$, $E^{(1)}$ and $H^{(1)}$. One can then use the calculus of totally characteristic Fourier Integral Operators of [10] to transform the operator, the characteristic surfaces and their intersections into model cases. Lemma 7.1 is then a consequence of the mapping properties of these operators.

Lemma 7.2 *Let $g \in L_{loc}^2(\Omega)$ be such that*

$$\beta^*g \in I_k L_{loc}^2(X, \partial X_1). \quad (7.3)$$

Then there exists $v_2, Dv_2 \in J_k(\Omega)$ such that $Pv_2 = g$.

The proof of Lemma 7.2 is considerably simpler than the one of Lemma 7.1, it is based on a commutator argument.

7.1 Marked Lagrangian Distributions

Let $\Lambda \subset T^*\Omega$ be a smooth conic closed Lagrangian and let $S_2 \subset S_1 \subset \Lambda$ be conic smooth hypersurfaces. Denote

$$\mathcal{M}(\Lambda)_1 = \{A \in \Psi^1(\Omega) : a = \sigma^1(A) = 0 \text{ at } \Lambda_\Lambda, \quad (7.4)$$

$$H_a \text{ tangent to } S_1 \text{ and to } S_2\} \quad (7.5)$$

and define

$$I_k L_c^2(\Omega, \mathcal{M}(\Lambda)_1) = \{u \in L_c^2(\Omega) : \mathcal{M}(\Lambda)_1^j u \in L_{loc}^2(\Omega), \quad j \leq k\}. \quad (7.6)$$

A detailed study of these distributions can be found in [8]. As mentioned in Section 2, the marked Lagrangian Distributions were first introduced by Melrose in [9] to study the cusp case.

Let $\Lambda_\Sigma = \text{clos}N^*(\Sigma_{reg})$, $\Lambda_Q = \text{clos}N^*(Q \setminus O)$. It is well known that Λ_Σ and Λ_Q are smooth conic Lagrangian submanifolds of $T^*\mathbf{R}^3$. Let $\Lambda_B = N^*B$ and let $\Lambda_O = T_O^*\mathbf{R}^3$, denote $S_1 = \Lambda_\Sigma \cap \Lambda_B = \Lambda_Q \cap \Lambda_B = \Lambda_\Sigma \cap \Lambda_Q$ and $S_2 = \Lambda_\Sigma \cap \Lambda_O$. Let $S_3 = \Lambda_O \cap \Lambda_Q$ and let $I_k L_{loc}^2(\Omega, \mathcal{M}(\Lambda_0)_3)$ be the space of marked Lagrangian distributions to Λ_0 marked by S_3 and S_2 .

In coordinates where (3.1) holds one obtains that $\mathcal{M}(\Sigma)_1$ is the $\Psi^0(\Omega)$ span of

$$V_1 = 4x\partial_x + 3y\partial_y + 2z\partial_z, \quad V_2 = (2xz - \frac{3}{4}y^2)\partial_x - \frac{1}{2}yz\partial_y + 4x\partial_z, \quad (7.7)$$

$$P_1 = z(\partial_y^2 - \partial_x\partial_z), \quad P_2 = y(\partial_y^2 - \partial_x\partial_z), \quad (7.8)$$

$$P_3 = 4\partial_z^2 + 2z\partial_y^2 + y\partial_y\partial_x, \quad P_4 = (\partial_y^2 - \partial_x\partial_z)\partial_z, \quad (7.9)$$

$$P_5 = (\partial_y^2 - \partial_x\partial_z)\partial_y. \quad (7.10)$$

Times elliptic factors of the appropriate orders. The space of marked Lagrangian distributions to the swallowtail marked by S and S_1 is however too small for our purposes, we shall need a slightly bigger one. Let $P'_5 = (3\partial_y^2 - 8\partial_x\partial_z - 12z\partial_x^2)\partial_y^2$ and define the space of "supermarked" Lagrangian distributions to Λ_Σ , S and S_1 as

$$I_{3k} L_c^2(\Omega, \mathcal{M}(\Lambda_\Sigma)_1)^s = \{u \in L_c^2(\Omega) : V_1^{\alpha_1} V_2^{\alpha_2} P_1^{\ell_1} P_2^{\ell_2} P_3^{\ell_3} P_4^{\ell_4} P_5^{\ell_5} u \in H_c^{-\ell}(\Omega), \ell = \ell_1 + \ell_2 + \ell_3 + \ell_4 + 6\ell_5 \leq 3k\}. \quad (7.11)$$

Where the superscript s is for "supermarked". The spaces of supermarked Lagrangians was introduced by M. Zworski in [18] where a more detailed description of those spaces is given. One defines the space $I_k L_c^2(\Omega, \mathcal{M}(\Sigma)_1)^s$ for all integers k by complex interpolation. One can easily show that

$$I_k L_c^2(\Omega, \mathcal{M}(\Lambda_\Sigma)_1) \subset I_k L_c^2(\Omega, \mathcal{M}(\Lambda_\Sigma)_1)^s. \quad (7.12)$$

Let

$$M_k(\Omega) = I_k L_c^2(\Omega, \mathcal{M}(\Lambda_\Sigma)_1)^s + I_k L_c^2(\Omega, \mathcal{M}(\Lambda_Q)_1) + I_k L_c^2(\Omega, \mathcal{M}(\Lambda_B)_1) + I_k L_c^2(\Omega, \mathcal{M}(\Lambda_O)_3) \quad (7.13)$$

be the space of marked Lagrangian distributions to Σ , Q and B .

Lemma 7.3 *Let $g \in J_k(\Omega)$ be such that β^*g is supported away from $E^{(1)}$, $H^{(1)}$ and $L^{(2)}$, then $g \in M_k(\Omega)$.*

The proof of Lemma 7.3 is quite long and consists basically of lifting the generators of each of the components of M_k under the map β . Now we are going to use the same idea as in the case of the cusp, first we prove a propagation theorem for $M_k(\Omega)$ and then use again the equation to show that the solution is in fact in the smaller space $J_k(\Omega)$. By commutator methods one can prove

Lemma 7.4 *Let $f \in M_k(\Omega)$, there exist $v_3, Dv_3 \in M_k(\Omega)$ such that $Pv_3 = f$.*

Then one proves an elliptic regularity type of Theorem which states that

Lemma 7.5 *Let $v, Dv \in M_k(\Omega)$ be such that $Pv \in J_k(\Omega)$. Then $v, Dv \in J_k(\Omega)$.*

When one lifts $v \in M_k(\Omega)$ under the map β one finds that it may be singular at some circles at the boundary of X , but it turns out that the lift of operator P under the map β is elliptic in some directions of ${}^bT^*X$ over those circles and therefore one concludes that if v satisfies the inclusion $Pv \in J_k(\Omega)$, then $v \in J_k(\Omega)$. This is the reason why one has to include the great circles in the definition of the spaces, since the hypersurfaces $\{x = 0\}$ and $\{z = 0\}$ are characteristic for P_0 the lift of the operator P could not be elliptic on circles $C_1^{(2)}$ and $C_2^{(2)}$.

Conclusion of the proof of Theorem 7.1:

Let v_1, v_2 and v_3 be as in Lemmas 7.1, 7.2 and 7.3 and $w = u - v_1 - v_2 - v_3$. Then

$$Pw = 0, \quad w \in J_k(\Omega) \text{ in } t < 0. \quad (7.14)$$

Let

$$\mathcal{M}(\Lambda_Q \cup \Lambda_\Sigma) = \{A \in \Psi^1(\Omega) : a = \sigma^1(A) = 0 \text{ on } \Lambda_Q \cup \Lambda_\Sigma\} \quad (7.15)$$

Equation (7.14) implies that

$$w, Dw \in I_k L_{loc}^2(\Omega^-, \mathcal{M}(\Lambda_Q \cup \Lambda_\Sigma)). \quad (7.16)$$

By commutator methods one can easily show that

$$w, Dw \in I_k L_{loc}^2(\Omega, \mathcal{M}(\Lambda_Q \cup \Lambda_\Sigma)). \quad (7.17)$$

By the arguments used in the proof of Lemma 7.3 one can show that

$$I_k L_{loc}^2(\Omega, \mathcal{M}(\Lambda_Q \cup \Lambda_\Sigma)) \subset J_k(\Omega). \quad (7.18)$$

This concludes the proof of Theorem 7.1.
