On inhomogeneous Diophantine approximation with some quasi-periodic expressions, II

par TAKAO KOMATSU

RÉSUMÉ. On s'intéresse aux valeurs de

$$\mathcal{M}(\theta, \phi) = \liminf_{|q| \rightarrow \infty} |q| \|q\theta - \phi\|$$

lorsque θ est un réel ayant un développement en fraction continue quasi-périodique.

ABSTRACT. We consider the values concerning

$$\mathcal{M}(\theta, \phi) = \liminf_{|q| \rightarrow \infty} |q| \|q\theta - \phi\|$$

where the continued fraction expansion of θ has a quasi-periodic form. In particular, we treat the cases so that each quasi-periodic form includes no constant. Furthermore, we give some general conditions satisfying $\mathcal{M}(\theta, \phi) = 0$.

1. INTRODUCTION

Let θ be irrational and ϕ real. We suppose throughout that $q\theta - \phi$ is never integral for any integer q . Define the value of the function

$$\mathcal{M}(\theta, \phi) = \liminf_{|q| \rightarrow \infty} |q| \|q\theta - \phi\|,$$

which is called *inhomogeneous approximation constant* for the pair θ, ϕ . It is convenient to introduce the functions

$$\mathcal{M}_+(\theta, \phi) = \liminf_{q \rightarrow +\infty} q \|q\theta - \phi\|$$

and

$$\mathcal{M}_-(\theta, \phi) = \liminf_{q \rightarrow +\infty} q \|q\theta + \phi\| = \liminf_{q \rightarrow -\infty} |q| \|q\theta - \phi\|.$$

Then $\mathcal{M}(\theta, \phi) = \min(\mathcal{M}_+(\theta, \phi), \mathcal{M}_-(\theta, \phi))$. Several authors have treated $\mathcal{M}(\theta, \phi)$ or $\mathcal{M}_+(\theta, \phi)$ by using their own algorithms (See [1], [2], [4], [5], [11] e.g.), but it has been difficult to find the exact values of $\mathcal{M}(\theta, \phi)$ for

the concrete pair of θ and ϕ . For example, Cusick, Rockett and Szűs ([2]) obtain

$$\mathcal{M}\left(\theta, \frac{1}{2}\right) = \frac{1}{4\sqrt{5}} \quad \text{and} \quad \mathcal{M}\left(\theta, \frac{1}{\sqrt{5}}\right) = \frac{1}{5\sqrt{5}}$$

when $\theta = (1 + \sqrt{5})/2 = [1; 1, 1, \dots]$. And author ([5]) obtains

$$\begin{aligned} \mathcal{M}\left(\theta, \frac{1}{a}\right) &= \frac{1}{a^2\sqrt{a^2+4}}, \\ \mathcal{M}\left(\theta, \frac{1}{2a}\right) &= \frac{1}{4a^2\sqrt{a^2+4}}, \\ \mathcal{M}\left(\theta, \frac{1}{a^2+4}\right) &= \frac{1}{(a^2+4)\sqrt{a^2+4}} \quad \text{and} \\ \mathcal{M}\left(\theta, \frac{1}{2}\right) &= \frac{1}{4\sqrt{a^2+4}} \quad (a \text{ is odd } \geq 3) \end{aligned}$$

when $\theta = (\sqrt{a^2+4} - a)/2 = [0; a, a, \dots]$. However, it is not easy to apply these methods to find the value $\mathcal{M}(\theta, \phi)$ about the different types of θ .

In [6] author establishes the relationship between $\mathcal{M}(\theta, \phi)$ and the algorithm of Nishioka, Shiokawa and Tamura. If we use this result, we can evaluate the exact value of $\mathcal{M}(\theta, \phi)$ for any pair of θ and ϕ at least when θ is a positive real root of the quadratic equation and $\phi \in \mathbb{Q}(\theta)$. For example,

$$\begin{aligned} \mathcal{M}\left(\theta, \frac{1}{2}\right) &= \begin{cases} \frac{\min(a,b)}{4\sqrt{D}} & \text{if both } a \text{ and } b \text{ are odd,} \\ \frac{a}{4\sqrt{D}} & \text{otherwise,} \end{cases} \\ \mathcal{M}\left(\theta, \frac{1}{\sqrt{D}}\right) &= \frac{a}{D\sqrt{D}} \quad \text{and} \\ \mathcal{M}\left(\theta, \frac{1}{a}\right) &= \frac{1}{a\sqrt{D}} \quad (a \geq 2) \quad (D = ab(ab+4)) \end{aligned}$$

are given when $\theta = (\sqrt{ab(ab+4)} - ab)/(2a) = [0; a, b, a, b, \dots]$.

Furthermore, in [7] author is so successful applying the Nishioka-Shiokawa-Tamura algorithm that the exact value of $\mathcal{M}(\theta, \phi)$ can be calculated even if θ is a Hurwitzian number, namely its continued fraction expansion has a quasi-periodic form. And it is the first time to find a concrete pair of θ and ϕ so that $\mathcal{M}(\theta, \phi) = 0$. For example, for a positive integer s

$$\mathcal{M}\left(e^{\frac{1}{s}}, \frac{1}{3}\right) = \begin{cases} 0 & \text{if } s \equiv 2 \pmod{3}, \\ \frac{1}{18} & \text{otherwise} \end{cases}$$

is given.

In this paper we consider the cases so that each quasi-periodic form includes no constant, and conditions satisfying $\mathcal{M}(\theta, \phi) = 0$.

2. NST ALGORITHM

We first introduce the NST algorithm ([9]). $\theta = [a_0; a_1, a_2, \dots]$ denotes the continued fraction expansion of θ , where

$$\begin{aligned}\theta &= a_0 + \theta_0, & a_0 &= [\theta], \\ 1/\theta_{n-1} &= a_n + \theta_n, & a_n &= [1/\theta_{n-1}] \quad (n = 1, 2, \dots).\end{aligned}$$

The k -th convergent $p_k/q_k = [a_0; a_1, \dots, a_k]$ of θ is then given by the recurrence relations

$$\begin{aligned}p_k &= a_n p_{k-1} + p_{k-2} & (k = 0, 1, \dots), & & p_{-2} &= 0, & p_{-1} &= 1, \\ q_k &= a_k q_{k-1} + q_{k-2} & (k = 0, 1, \dots), & & q_{-2} &= 1, & q_{-1} &= 0.\end{aligned}$$

Denote $\phi = {}_\theta[b_0; b_1, b_2, \dots]$ be the expansion of ϕ in terms of the sequence $\{\theta_0, \theta_1, \dots\}$, where

$$\begin{aligned}\phi &= b_0 - \phi_0, & b_0 &= [\phi], \\ \phi_{n-1}/\theta_{n-1} &= b_n - \phi_n, & b_n &= [\phi_{n-1}/\theta_{n-1}] \quad (n = 1, 2, \dots).\end{aligned}$$

Then, ϕ is represented by

$$\begin{aligned}\phi &= b_0 - b_1\theta_0 + b_2\theta_0\theta_1 - \dots + (-1)^k b_k\theta_0\theta_1 \dots \theta_{k-1} - (-1)^k \theta_0\theta_1 \dots \theta_{k-1}\phi_k \\ &= b_0 - \sum_{k=0}^{\infty} (-1)^k b_{k+1}\theta_0\theta_1 \dots \theta_k = b_0 - \sum_{k=0}^{\infty} b_{k+1}D_k,\end{aligned}$$

where $D_k = q_k\theta - p_k = (-1)^k \theta_0\theta_1 \dots \theta_k$. Now, the following theorem is established in [6].

Theorem 1.

$$\mathcal{M}_-(\theta, \phi) = \liminf_{n \rightarrow +\infty} \min(B_n \|B_n\theta + \phi\|, B_n^* \|B_n^*\theta + \phi\|),$$

where $B_n = \sum_{k=1}^n b_k q_{k-1}$ and $B_n^* = B_n - q_{n-1}$.

Remark. It is also known in [6] that $\|B_n\theta + \phi\| = \phi_n |D_{n-1}|$ and $\|B_n^*\theta + \phi\| = (1 - \phi_n) |D_{n-1}|$. Together with $\mathcal{M}_+(\theta, \phi) = \mathcal{M}_-(\theta, 1 - \phi)$, one can obtain the value $\mathcal{M}(\theta, \phi)$.

3. THE CASE $\mathcal{M}(\theta, \phi) = 0$

Continued fraction expansions of the form

$$[c_0; c_1, \dots, c_n, \overline{Q_1(k), \dots, Q_p(k)}]_{k=1}^{\infty}$$

are called *Hurwitzian* if c_0 is an integer, c_1, \dots, c_n are positive integers, $Q_1(k), \dots, Q_p(k)$ are polynomials with rational coefficients which takes positive integral values for $k = 1, 2, \dots$ and at least one of the polynomials

is not constant. $Q_1(k), \dots, Q_p(k)$ are said to form a *quasi-period*. The expansions

$$e = [2; \overline{1, 2k, 1}]_{k=1}^{\infty} \quad \text{and} \quad e^{1/s} = [1; \overline{(2k-1)s-1, 1, 1}]_{k=1}^{\infty}$$

where s is a positive integer with $s \geq 2$, are well-known examples (See [3], [8], [10] e.g.). In [7] for a positive integer s we have $\mathcal{M}(e^{1/s}, (e^{1/s}-1)/2) = 0$, $\mathcal{M}(e^{1/s}, 1/2) = 1/8$ and $\mathcal{M}(e^{1/s}, 1/3) = 0$ if $s \equiv 2 \pmod{3}$; $1/18$ otherwise.

Then, what is the condition such that $\mathcal{M}(\theta, \phi) = 0$ holds? It seems that a non-constant polynomial in a quasi-periodic part influences whether $\mathcal{M}(\theta, \phi) = 0$ or not. So, we consider the cases each quasi-periodic form includes no constant.

$$\frac{e^{1/s} - 1}{e^{1/s} + 1} = [0; \overline{(4k-2)s}]_{k=1}^{\infty},$$

where s is a positive integer, or

$$\frac{e^{2/s} - 1}{e^{2/s} + 1} = [0; \overline{(2k-1)s}]_{k=1}^{\infty},$$

where s is an odd positive integer with $s \geq 3$, is one of the well-known examples (See [10] e.g.).

In any of two expansions of θ above a_k is increasing and $a_k \rightarrow \infty$ ($k \rightarrow \infty$). So, one may be apt to conjecture that $\mathcal{M}(\theta, \phi) = 0$ for almost all of ϕ . But, there is a case satisfying $\mathcal{M}(\theta, \phi) \neq 0$.

Theorem 2.

$$\mathcal{M}\left(\frac{e^{1/s} - 1}{e^{1/s} + 1}, \frac{e^{1/s}}{e^{1/s} + 1}\right) = \frac{1}{4}.$$

Proof. First, note that in the expansion of $\theta = (e^{1/s} - 1)/(e^{1/s} + 1)$

$$a_n = (4n-2)s \rightarrow \infty \quad (n = 1, 2, \dots \rightarrow \infty),$$

yielding

$$\theta_{n-1} = \frac{1}{a_n + \theta_n} \rightarrow 0 \quad (n = 1, 2, \dots \rightarrow \infty).$$

It is convenient to see that

$$q_n |D_{n-1}| = \frac{1}{1 + \theta_n q_{n-1}/q_n} \rightarrow 1 \quad (n = 1, 2, \dots \rightarrow \infty)$$

and

$$q_{n-1} |D_{n-1}| = \frac{1}{(4n-2)s + \theta_n + q_{n-2}/q_{n-1}} \rightarrow 0 \quad (n = 1, 2, \dots \rightarrow \infty).$$

$\phi = (\theta + 1)/2 = e^{1/s}/(e^{1/s} + 1)$ is expanded as

$$\phi = [1; \overline{(2k-1)s}]_{k=1}^{\infty} = [1; \overline{a_k/2}]_{k=1}^{\infty}$$

and

$$\phi_n = \frac{1 - \theta_n}{2} \rightarrow \frac{1}{2} \quad (n = 0, 1, 2, \dots \rightarrow \infty).$$

For $n = 1, 2, \dots$

$$B_n = \sum_{i=1}^n \frac{a_i}{2} q_{i-1} = \frac{q_n + q_{n-1} - 1}{2}.$$

Hence,

$$\begin{aligned} B_n \|B_n \theta + \phi\| &= B_n \phi_n |D_{n-1}| \\ &= \frac{1}{2} (q_n |D_{n-1}| + q_{n-1} |D_{n-1}| - |D_{n-1}|) \phi_n \\ &\rightarrow \frac{1}{2} (1 + 0 - 0) \cdot \frac{1}{2} = \frac{1}{4} \quad (n \rightarrow \infty) \end{aligned}$$

and

$$\begin{aligned} B_n^* \|B_n^* \theta + \phi\| &= (B_n - q_{n-1}) (1 - \phi_n) |D_{n-1}| \\ &= \frac{1}{2} (q_n |D_{n-1}| - q_{n-1} |D_{n-1}| - |D_{n-1}|) (1 - \phi_n) \\ &\rightarrow \frac{1}{2} (1 - 0 - 0) \left(1 - \frac{1}{2}\right) = \frac{1}{4} \quad (n \rightarrow \infty), \end{aligned}$$

yielding that $\mathcal{M}_-(\theta, \phi) = 1/4$.

Next, $1 - \phi = (1 - \theta)/2 = 1/(e^{1/s} + 1)$ is expanded as

$$1 - \phi = [1; s + 1, \overline{(2k-1)s}]_{k=2}^{\infty} = [1; a_1/2 + 1, \overline{a_k/2}]_{k=2}^{\infty}$$

and

$$\phi_0 = \frac{1 + \theta_0}{2}, \quad \phi_n = \frac{1 - \theta_n}{2} \rightarrow \frac{1}{2} \quad (n = 1, 2, \dots \rightarrow \infty).$$

For $n = 1, 2, \dots$

$$B_n = 1 + \sum_{i=1}^n \frac{a_i}{2} q_{i-1} = \frac{q_n + q_{n-1} + 1}{2}.$$

In a similar manner, by

$$B_n \|B_n \theta - \phi\| \rightarrow \frac{1}{4} \quad \text{and} \quad B_n^* \|B_n^* \theta - \phi\| \rightarrow \frac{1}{4} \quad (n \rightarrow \infty)$$

one has $\mathcal{M}_+(\theta, \phi) = 1/4$. Therefore, $\mathcal{M}(\theta, \phi) = \mathcal{M}_{\pm}(\theta, \phi) = 1/4$. \square

Contrary to this result, there is, of course, a case satisfying $\mathcal{M}(\theta, \phi) = 0$.

Theorem 3.

$$\mathcal{M}\left(\frac{e^{1/s} - 1}{e^{1/s} + 1}, \frac{1}{2}\right) = 0.$$

Remark. It is interesting to see that in [7]

$$\mathcal{M}\left(e^{1/s}, \frac{e^{1/s} - 1}{2}\right) = 0 \quad \text{and} \quad \mathcal{M}\left(e^{1/s}, \frac{1}{2}\right) = \frac{1}{8} \neq 0$$

in comparison with Theorem 2 above and this Theorem.

Proof. $\phi = 1/2$ is expanded as

$$\begin{aligned} 1/2 &= \not\llbracket 1; s+1, \overline{(8k-2)s, (4k+1)s} \rrbracket_{k=1}^{\infty} \\ &= \not\llbracket 1; a_1/2+1, \overline{a_{2k}, a_{2k+1}/2} \rrbracket_{k=1}^{\infty} \end{aligned}$$

and $\phi_0 = 1/2$, for $n = 1, 2, \dots$

$$\phi_{2n-1} = 1 - \frac{1}{2}\theta_{2n-1} \rightarrow 1, \quad \phi_{2n} = \frac{1}{2} - \theta_{2n} \rightarrow \frac{1}{2} \quad (n \rightarrow \infty).$$

Since for $n = 1, 2, \dots$

$$B_{2n-1} = \frac{a_1}{2} + 1 + \sum_{i=1}^{n-1} \left(a_{2i}q_{2i-1} + \frac{1}{2}a_{2i+1}q_{2i} \right) = \frac{1}{2}q_{2n-1} + q_{2n-2},$$

one finds that

$$\begin{aligned} B_{2n-1} \|B_{2n-1}\theta + \phi\| &= B_{2n-1}\phi_{2n-1}|D_{2n-2}| \\ &= \left(\frac{1}{2}q_{2n-1}|D_{2n-2}| + q_{2n-2}|D_{2n-2}| \right) \phi_{2n-1} \\ &\rightarrow \left(\frac{1}{2} \cdot 1 + 0 \right) \cdot 1 = \frac{1}{2}, \end{aligned}$$

$$\begin{aligned} B_{2n-1}^* \|B_{2n-1}^*\theta + \phi\| &= (B_{2n-1} - q_{2n-2})(1 - \phi_{2n-1})|D_{2n-2}| \\ &= \frac{1}{2}q_{2n-1}|D_{2n-2}|(1 - \phi_{2n-1}) \rightarrow \frac{1}{2} \cdot 1 \cdot (1 - 1) = 0, \end{aligned}$$

$$\begin{aligned} B_{2n} \|B_{2n}\theta + \phi\| &= (B_{2n-1} + b_{2n}q_{2n-1})\phi_{2n}|D_{2n-1}| \\ &= \left(q_{2n}|D_{2n-1}| + \frac{1}{2}q_{2n-1}|D_{2n-1}| \right) \phi_{2n} \\ &\rightarrow \left(1 + \frac{1}{2} \cdot 0 \right) \cdot \frac{1}{2} = \frac{1}{2}, \end{aligned}$$

$$\begin{aligned} B_{2n}^* \|B_{2n}^*\theta + \phi\| &= (B_{2n} - q_{2n-1})(1 - \phi_{2n})|D_{2n-1}| \\ &= \left(q_{2n}|D_{2n-1}| - \frac{1}{2}q_{2n-1}|D_{2n-1}| \right) (1 - \phi_{2n}) \\ &\rightarrow \left(1 - \frac{1}{2} \cdot 0 \right) \left(1 - \frac{1}{2} \right) = \frac{1}{2} \end{aligned}$$

as n tends to infinity. Therefore, we have $\mathcal{M}(\theta, 1/2) = \mathcal{M}_{\pm}(\theta, 1/2) = 0$. \square

We shall show one more case satisfying $\mathcal{M}(\theta, \phi) = 0$.

Theorem 4.

$$\mathcal{M}\left(\frac{e^{1/s} - 1}{e^{1/s} + 1}, \frac{1}{3}\right) = 0.$$

Proof. When $s \equiv 0 \pmod{3}$, $\phi = 1/3$ is expanded as

$$\frac{1}{3} = [1; \frac{2}{3}a_1 + 1, \overline{\frac{2}{3}a_{2k}}, \frac{2}{3}a_{2k+1}]_{k=1}^{\infty}$$

and $\phi_0 = 2/3$, for $n = 1, 2, \dots$

$$\phi_{2n-1} = 1 - \frac{2}{3}\theta_{2n-1} \rightarrow 1, \quad \phi_{2n} = \frac{2}{3} - \theta_{2n} \rightarrow \frac{2}{3} \quad (n \rightarrow \infty).$$

Since for $n = 1, 2, \dots$

$$B_{2n-1} = \frac{2}{3}a_1 + 1 + \sum_{i=1}^{n-1} \left(a_{2i}q_{2i-1} + \frac{2}{3}a_{2i+1}q_{2i} \right) = \frac{2}{3}q_{2n-1} + q_{2n-2},$$

one finds that

$$\begin{aligned} B_{2n-1}^* \|B_{2n-1}^* \theta + \phi\| &= (B_{2n-1} - q_{2n-2})(1 - \phi_{2n-1})|D_{2n-2}| \\ &= \frac{2}{3}q_{2n-1}|D_{2n-2}|(1 - \phi_{2n-1}) \rightarrow \frac{2}{3} \cdot 1 \cdot (1 - 1) = 0, \end{aligned}$$

as n tends to infinity. Hence, we have $\mathcal{M}_-(\theta, 1/3) = 0$.

$1 - \phi = 2/3$ is expanded as

$$\frac{2}{3} = [1; \frac{1}{3}a_1 + 1, \overline{\frac{1}{3}a_{2k}}, \frac{1}{3}a_{2k+1}]_{k=1}^{\infty}$$

and $\phi_0 = 1/3$, for $n = 1, 2, \dots$

$$\phi_{2n-1} = 1 - \frac{1}{3}\theta_{2n-1} \rightarrow 1, \quad \phi_{2n} = \frac{1}{3} - \theta_{2n} \rightarrow \frac{1}{3} \quad (n \rightarrow \infty).$$

Since for $n = 1, 2, \dots$

$$B_{2n-1} = \frac{1}{3}a_1 + 1 + \sum_{i=1}^{n-1} \left(a_{2i}q_{2i-1} + \frac{1}{3}a_{2i+1}q_{2i} \right) = \frac{1}{3}q_{2n-1} + q_{2n-2},$$

one finds that

$$\begin{aligned} B_{2n-1}^* \|B_{2n-1}^* \theta - \phi\| &= (B_{2n-1} - q_{2n-2})(1 - \phi_{2n-1})|D_{2n-2}| \\ &= \frac{1}{3}q_{2n-1}|D_{2n-2}|(1 - \phi_{2n-1}) \rightarrow \frac{1}{3} \cdot 1 \cdot (1 - 1) = 0, \end{aligned}$$

as n tends to infinity. Hence, we have $\mathcal{M}_+(\theta, 1/3) = 0$.

Therefore, $\mathcal{M}(\theta, 1/3) = 0$.

When $s \equiv 1 \pmod{3}$, $\phi = 1/3$ is expanded as

$$\frac{1}{3} = \not d[1; \frac{2}{3}(a_1 + 1), \overline{\frac{2}{3}a_{6k-4}, \frac{2a_{6k-3} + 1}{3}, a_{6k-2}, \frac{2}{3}a_{6k-1}, a_{6k}, \frac{2a_{6k+1} - 1}{3}}]_{k=1}^{\infty}$$

and $\phi_0 = 2/3$, for $n = 1, 2, \dots$

$$\begin{aligned} \phi_{6n-5} &= \frac{2}{3}(1 - \theta_{6n-5}) \rightarrow \frac{2}{3}, & \phi_{6n-4} &= \frac{2}{3}(1 - \theta_{6n-4}) \rightarrow \frac{2}{3}, \\ \phi_{6n-3} &= 1 - \frac{2}{3}\theta_{6n-3} \rightarrow 1, & \phi_{6n-2} &= \frac{2}{3} - \theta_{6n-2} \rightarrow \frac{2}{3}, \\ \phi_{6n-1} &= 1 - \frac{2}{3}\theta_{6n-1} \rightarrow 1, & \phi_{6n} &= \frac{2}{3} - \theta_{6n} \rightarrow \frac{2}{3} \end{aligned}$$

as n tends to infinity. Since for $n = 1, 2, \dots$

$$\begin{aligned} B_{6n-5} &= \frac{2}{3}(a_1 + 1) + \sum_{i=1}^{n-1} \left(\frac{2}{3}a_{6i-4}q_{6i-5} + \frac{2a_{6i-3} + 1}{3}q_{6i-4} \right. \\ &\quad \left. + a_{6i-2}q_{6i-3} + \frac{2}{3}a_{6i-1}q_{6i-2} + a_{6i}q_{6i-1} + \frac{2a_{6i+1} - 1}{3}q_{6i} \right) \\ &= \frac{2}{3}(q_{6n-5} + q_{6n-6}), \end{aligned}$$

one finds that

$$\begin{aligned} B_{6n-3}^* \|B_{6n-3}^* \theta + \phi\| &= (B_{6n-3} - q_{6n-4})(1 - \phi_{6n-3})|D_{6n-6}| \\ &= \frac{2}{3}q_{6n-3}|D_{6n-4}|(1 - \phi_{6n-3}) \rightarrow \frac{2}{3} \cdot 1 \cdot (1 - 1) = 0, \\ B_{6n-1}^* \|B_{6n-1}^* \theta + \phi\| &= \frac{2}{3}q_{6n-1}|D_{6n-2}|(1 - \phi_{6n-1}) \rightarrow \frac{2}{3} \cdot 1 \cdot (1 - 1) = 0, \end{aligned}$$

as n tends to infinity. Hence, we have $\mathcal{M}_-(\theta, 1/3) = 0$.

$1 - \phi = 2/3$ is expanded as

$$\frac{2}{3} = \not d[1; \frac{1}{3}(a_1 + 1), \overline{\frac{1}{3}a_{6k-4}, \frac{a_{6k-3} + 2}{3}, a_{6k-2}, \frac{1}{3}a_{6k-1}, a_{6k}, \frac{a_{6k+1} - 2}{3}}]_{k=1}^{\infty}$$

and $\phi_0 = 1/3$, for $n = 1, 2, \dots$

$$\begin{aligned} \phi_{6n-5} &= \frac{1}{3}(1 - \theta_{6n-5}) \rightarrow \frac{1}{3}, & \phi_{6n-4} &= \frac{1}{3}(1 - \theta_{6n-4}) \rightarrow \frac{1}{3}, \\ \phi_{6n-3} &= 1 - \frac{1}{3}\theta_{6n-3} \rightarrow 1, & \phi_{6n-2} &= \frac{1}{3} - \theta_{6n-2} \rightarrow \frac{1}{3}, \\ \phi_{6n-1} &= 1 - \frac{1}{3}\theta_{6n-1} \rightarrow 1, & \phi_{6n} &= \frac{1}{3} - \theta_{6n} \rightarrow \frac{1}{3} \end{aligned}$$

as n tends to infinity. Since for $n = 1, 2, \dots$

$$B_{6n-5} = \frac{1}{3}(q_{6n-5} + q_{6n-6}),$$

one finds that

$$B_{6n-3}^* \|B_{6n-3}^* \theta - \phi\| = \frac{1}{3} q_{6n-3} |D_{6n-4}| (1 - \phi_{6n-3}) \rightarrow \frac{1}{3} \cdot 1 \cdot (1 - 1) = 0,$$

$$B_{6n-1}^* \|B_{6n-1}^* \theta - \phi\| = \frac{1}{3} q_{6n-1} |D_{6n-2}| (1 - \phi_{6n-1}) \rightarrow \frac{1}{3} \cdot 1 \cdot (1 - 1) = 0,$$

as n tends to infinity. Hence, we have $\mathcal{M}_+(\theta, 1/3) = 0$.

Therefore, $\mathcal{M}(\theta, 1/3) = 0$.

When $s \equiv 2 \pmod{3}$, $\phi = 1/3$ is expanded as

$$\frac{1}{3} = \not\approx 1; \frac{2a_1 + 1}{3}, \overline{\frac{1}{3}a_{6k-4}, \frac{2}{3}(a_{6k-3} + 1), a_{6k-2}, \frac{2}{3}a_{6k-1}, a_{6k}, \frac{2}{3}(a_{6k+1} - 1)}]_{k=1}^{\infty}$$

and $\phi_0 = 2/3$, for $n = 1, 2, \dots$

$$\phi_{6n-5} = \frac{1}{3}(1 - 2\theta_{6n-5}) \rightarrow \frac{1}{3}, \quad \phi_{6n-4} = \frac{1}{3}(2 - \theta_{6n-4}) \rightarrow \frac{2}{3},$$

$$\phi_{6n-3} = 1 - \frac{2}{3}\theta_{6n-3} \rightarrow 1, \quad \phi_{6n-2} = \frac{2}{3} - \theta_{6n-2} \rightarrow \frac{2}{3},$$

$$\phi_{6n-1} = 1 - \frac{2}{3}\theta_{6n-1} \rightarrow 1, \quad \phi_{6n} = \frac{2}{3} - \theta_{6n} \rightarrow \frac{2}{3}$$

as n tends to infinity. Since for $n = 1, 2, \dots$

$$\begin{aligned} B_{6n-5} &= \frac{2a_1 + 1}{3} + \sum_{i=1}^{n-1} \left(\frac{1}{3} a_{6i-4} q_{6i-5} + \frac{2}{3} (a_{6i-3} + 1) q_{6i-4} \right. \\ &\quad \left. + a_{6i-2} q_{6i-3} + \frac{2}{3} a_{6i-1} q_{6i-2} + a_{6i} q_{6i-1} + \frac{2}{3} (a_{6i+1} - 1) q_{6i} \right) \\ &= \frac{1}{3} (2q_{6n-5} + q_{6n-6}), \end{aligned}$$

one finds that

$$B_{6n-3}^* \|B_{6n-3}^* \theta + \phi\| = \frac{2}{3} q_{6n-3} |D_{6n-4}| (1 - \phi_{6n-3}) \rightarrow \frac{2}{3} \cdot 1 \cdot (1 - 1) = 0,$$

$$B_{6n-1}^* \|B_{6n-1}^* \theta + \phi\| = \frac{2}{3} q_{6n-1} |D_{6n-2}| (1 - \phi_{6n-1}) \rightarrow \frac{2}{3} \cdot 1 \cdot (1 - 1) = 0,$$

as n tends to infinity. Hence, we have $\mathcal{M}_-(\theta, 1/3) = 0$.

$1 - \phi = 2/3$ is expanded as

$$\frac{2}{3} = \not\approx 1; \frac{a_1 + 2}{3}, \overline{\frac{2}{3}a_{6k-4}, \frac{a_{6k-3} + 1}{3}, a_{6k-2}, \frac{1}{3}a_{6k-1}, a_{6k}, \frac{a_{6k+1} - 1}{3}}]_{k=1}^{\infty}$$

and $\phi_0 = 1/3$, for $n = 1, 2, \dots$

$$\begin{aligned}\phi_{6n-5} &= \frac{1}{3}(2 - \theta_{6n-5}) \rightarrow \frac{2}{3}, & \phi_{6n-4} &= \frac{1}{3}(1 - 2\theta_{6n-4}) \rightarrow \frac{1}{3}, \\ \phi_{6n-3} &= 1 - \frac{1}{3}\theta_{6n-3} \rightarrow 1, & \phi_{6n-2} &= \frac{1}{3} - \theta_{6n-2} \rightarrow \frac{1}{3}, \\ \phi_{6n-1} &= 1 - \frac{1}{3}\theta_{6n-1} \rightarrow 1, & \phi_{6n} &= \frac{1}{3} - \theta_{6n} \rightarrow \frac{1}{3}\end{aligned}$$

as n tends to infinity. Since for $n = 1, 2, \dots$

$$B_{6n-5} = \frac{1}{3}(q_{6n-5} + 2q_{6n-6}),$$

one finds that

$$\begin{aligned}B_{6n-3}^* \|B_{6n-3}^* \theta - \phi\| &= \frac{1}{3}q_{6n-3}|D_{6n-4}|(1 - \phi_{6n-3}) \rightarrow \frac{1}{3} \cdot 1 \cdot (1 - 1) = 0, \\ B_{6n-1}^* \|B_{6n-1}^* \theta - \phi\| &= \frac{1}{3}q_{6n-1}|D_{6n-2}|(1 - \phi_{6n-1}) \rightarrow \frac{1}{3} \cdot 1 \cdot (1 - 1) = 0,\end{aligned}$$

as n tends to infinity. Hence, we have $\mathcal{M}_+(\theta, 1/3) = 0$.

Therefore, $\mathcal{M}(\theta, 1/3) = 0$. □

4. THE CASES $\mathcal{M}((e^{2/s} - 1)/(e^{2/s} + 1), \phi) = 0$

Let us calculate $\mathcal{M}(\theta, \phi)$ when

$$\theta = \frac{e^{2/s} - 1}{e^{2/s} + 1} = [0; \overline{(2k-1)s}]_{k=1}^\infty,$$

where s is an odd positive integer with $s \geq 3$. The situations are a little bit different from the previous results. Notice that $a_n = (2n-1)s \rightarrow \infty$, so $\theta_{n-1} = 1/(a_n + \theta_n) \rightarrow 0$ ($n = 1, 2, \dots \rightarrow \infty$). $\lim_{n \rightarrow \infty} q_n |D_{n-1}| = 1$ and $\lim_{n \rightarrow \infty} q_{n-1} |D_{n-1}| = 0$ hold for this θ too. The first result is quite different from Theorem 2.

Theorem 5.

$$\mathcal{M}\left(\frac{e^{2/s} - 1}{e^{2/s} + 1}, \frac{e^{2/s}}{e^{2/s} + 1}\right) = 0.$$

Proof. $\phi = (\theta + 1)/2 = e^{2/s}/(e^{2/s} + 1)$ is expanded as

$$\begin{aligned}\phi &= [1; \overline{\frac{(6k-5)s+1}{2}, (6k-3)s, \frac{(6k-1)s-1}{2}}]_{k=1}^\infty \\ &= [1; \overline{\frac{a_{3k-2}+1}{2}, a_{3k-1}, \frac{a_{3k}-1}{2}}]_{k=1}^\infty\end{aligned}$$

and

$$\begin{aligned}\phi_{3n} &= \frac{1 - \theta_{3n}}{2} \rightarrow \frac{1}{2} \quad (n = 0, 1, 2, \dots \rightarrow \infty), \\ \phi_{3n-2} &= 1 - \frac{1}{2}\theta_{3n-2} \rightarrow 1, \quad \phi_{3n-1} = \frac{1}{2} - \theta_{3n} \rightarrow \frac{1}{2} \quad (n = 1, 2, \dots \rightarrow \infty).\end{aligned}$$

Since for $n = 1, 2, \dots$

$$\begin{aligned}B_{3n} &= \sum_{i=1}^n \left(\frac{a_{3i-2} + 1}{2} q_{3i-3} + a_{3i-1} q_{3i-2} + \frac{a_{3i} - 1}{2} q_{3i-1} \right) \\ &= \frac{1}{2}(q_{3n} + q_{3n-1} - 1).\end{aligned}$$

one finds that

$$\begin{aligned}B_{3n+1}^* \|B_{3n+1}^* \theta + \phi\| &= (B_{3n+1} - q_{3n})(1 - \phi_{3n+1})|D_{3n}| \\ &= \frac{1}{2}(q_{3n+1}|D_{3n}| - |D_{3n}|)(1 - \phi_{3n+1}) \\ &\rightarrow \frac{1}{2}(1 - 0)(1 - 1) = 0 \quad (n \rightarrow \infty),\end{aligned}$$

yielding $\mathcal{M}_-(\theta, \phi) = 0$.

Next, $1 - \phi = (1 - \theta)/2 = 1/(e^{2/s} + 1)$ is expanded as

$$1 - \phi = \left[1; \frac{a_1 + 3}{2}, \frac{a_{3k} - 1}{2}, \frac{a_{3k+1} + 1}{2} \right]_{k=2}^{\infty}$$

and

$$\begin{aligned}\phi_0 &= \frac{1 + \theta_0}{2}, \quad \phi_{3n-2} = 1 - \frac{1}{2}\theta_{3n-2} \rightarrow 1, \\ \phi_{3n-1} &= \frac{1}{2} - \theta_{3n-1}, \quad \phi_{3n} = \frac{1}{2}(1 - \theta_{3n}) \rightarrow \frac{1}{2} \quad (n = 1, 2, \dots \rightarrow \infty).\end{aligned}$$

Since for $n = 1, 2, \dots$

$$B_{3n-2} = \frac{1}{2}q_{3n-2} + q_{3n-3} + \frac{1}{2}.$$

one finds that

$$\begin{aligned}B_{3n-2}^* \|B_{3n-2}^* \theta - \phi\| &= \frac{1}{2}(q_{3n-2}|D_{3n-3}| + |D_{3n-3}|)(1 - \phi_{3n-2}) \\ &\rightarrow \frac{1}{2}(1 + 0)(1 - 1) = 0 \quad (n \rightarrow \infty),\end{aligned}$$

yielding $\mathcal{M}_+(\theta, \phi) = 0$. Therefore, $\mathcal{M}(\theta, \phi) = \mathcal{M}_{\pm}(\theta, \phi) = 0$. \square

Theorem 6.

$$\mathcal{M}\left(\frac{e^{2/s} - 1}{e^{2/s} + 1}, \frac{1}{2}\right) = 0.$$

Proof. $\phi = 1/2$ is expanded as

$$\frac{1}{2} = \prod_{k=1}^{\infty} \left(1; \frac{a_1+1}{2}, \frac{a_{3k-1}+1}{2}, a_{3k}, \frac{a_{3k+1}-1}{2} \right)$$

and

$$\begin{aligned} \phi_0 &= \frac{1}{2}, & \phi_{3n-2} &= \frac{1}{2}(1 - \theta_{3n-2}) \rightarrow \frac{1}{2}, \\ \phi_{3n-1} &= 1 - \frac{1}{2}\theta_{3n-1} \rightarrow 1, & \phi_{3n} &= \frac{1}{2} - \theta_{3n} \rightarrow \frac{1}{2} \quad (n = 1, 2, \dots \rightarrow \infty). \end{aligned}$$

Since for $n = 1, 2, \dots$

$$\begin{aligned} B_{3n-2} &= \frac{a_1+1}{2} + \sum_{i=1}^{n-1} \left(\frac{a_{3i-1}+1}{2} q_{3i-2} + a_{3i} q_{3i-1} + \frac{a_{3i+1}-1}{2} q_{3i} \right) \\ &= \frac{1}{2}(q_{3n-2} + q_{3n-3}), \end{aligned}$$

one finds that

$$\begin{aligned} B_{3n-1}^* \|B_{3n-1}^* \theta + \phi\| &= (B_{3n-1} - q_{3n-2})(1 - \phi_{3n-1}) |D_{3n-2}| \\ &= \frac{1}{2} q_{3n-1} |D_{3n-2}| (1 - \phi_{3n-1}) \rightarrow \frac{1}{2} \cdot 1 \cdot (1 - 1) = 0 \end{aligned}$$

as n tends to infinity. Therefore, we have $\mathcal{M}(\theta, 1/2) = \mathcal{M}_{\pm}(\theta, 1/2) = 0$. \square

Theorem 7.

$$\mathcal{M} \left(\frac{e^{2/s} - 1}{e^{2/s} + 1}, \frac{1}{3} \right) = 0.$$

Proof. When $s \equiv 3, s \equiv 5, s \equiv 1 \pmod{6}$, the situation is completely the same as the case of

$$\theta = \frac{e^{1/s} - 1}{e^{1/s} + 1}$$

with $s \equiv 0, s \equiv 1, s \equiv 2 \pmod{3}$, respectively. \square

5. SOME CONDITIONS SATISFYING $\mathcal{M}(\theta, \phi) = 0$

We have already seen several examples so that $\mathcal{M}(\theta, \phi) = 0$ holds. Then, what is the condition of $\mathcal{M}(\theta, \phi) = 0$? Of course, the following is clear.

Theorem 8. *If $\phi_n \rightarrow 0$ or $\phi_n \rightarrow 1$ ($n \rightarrow \infty$) for infinitely many positive integers n , then $\mathcal{M}(\theta, \phi) = 0$.*

Proof. First, we shall show that $\theta_{n-1} < B_n |D_{n-1}| < 4$ for any positive integer n . Since

$$B_n = \sum_{i=1}^n b_i q_{i-1} \leq \sum_{i=1}^n (a_i + 1) q_{i-1} = q_n + 2q_{n-1} + (q_{n-2} + \dots + q_1) < 4q_n,$$

we obtain

$$B_n|D_{n-1}| < \frac{4q_n}{q_n + \theta_n q_{n-1}} < 4.$$

On the other hand,

$$B_n|D_{n-1}| \geq \frac{\sum_{i=1}^n q_{i-1}}{q_n + \theta_n q_{n-1}} > \frac{1}{a_n + \theta_n} = \theta_{n-1}.$$

If $\phi_n \rightarrow 0$ ($n \rightarrow \infty$), then

$$B_n \|B_n \theta + \phi\| = B_n |D_{n-1}| \phi_n \rightarrow 0 \quad (n \rightarrow \infty).$$

If $\phi_n \rightarrow 1$ ($n \rightarrow \infty$), then

$$B_n^* \|B_n^* \theta + \phi\| = B_n^* |D_{n-1}| (1 - \phi_n) \rightarrow 0 \quad (n \rightarrow \infty).$$

□

Corollary. When $b_n = 1$, $\phi_{n-1} \rightarrow 0$ if and only if $\phi_n \rightarrow 1$ ($n \rightarrow \infty$).

This is very generous. So, we state the following.

Theorem 9. If $|a_n - b_n| \leq c$ and $a_n \rightarrow \infty$ ($n \rightarrow \infty$) for infinitely many positive integers n , then $\mathcal{M}(\theta, \phi) = 0$. Here, c is a constant not depending upon n .

Remark. In fact, $a_n = b_n \rightarrow \infty$ ($n \rightarrow \infty$) holds in all previous theorems above implying $\mathcal{M}(\theta, \phi) = 0$.

Proof. If $|a_n - b_n| \leq c$, then $\frac{1}{\theta_{n-1}} - \frac{\phi_{n-1}}{\theta_{n-1}} < c + 2$ or $0 < 1 - \phi_{n-1} < (c + 2)\theta_{n-1}$. And if $\lim_{n \rightarrow \infty} a_n = \infty$, then

$$\theta_{n-1} = \frac{1}{a_n + \theta_n} \rightarrow 0 \quad (n \rightarrow \infty).$$

Thus, $1 - \phi_{n-1} \rightarrow 0$ ($n \rightarrow \infty$) entails that

$$B_{n-1}^* \|B_{n-1}^* \theta + \phi\| = B_{n-1}^* |D_{n-2}| (1 - \phi_{n-1}) \rightarrow 0 \quad (n \rightarrow \infty).$$
