THE NILPOTENT MODEL FOR A FUNCTION SPACE

by C. WATKISS

INTRODUCTION. - The purpose of these notes is to describe Sullivan's construction of a nilpotent model for a function space Y^X . The motivating idea is to assume the existence of a cocommutative chain theory from topological spaces to coalgebras (which, by abuse of notation, we write as $X \mapsto X$). One then simply translates the universal properties of Y^X into algebraic universal properties, and solves the corresponding algebraic problem.

For example, there is an evaluation map $Y^X \times X \xrightarrow{ev} Y$ such that, given any continuous map $Z \times X \xrightarrow{e} Y$ there exists a unique map $\phi : Z \rightarrow Y^X$ such that the diagram

$$(\times) \quad \begin{array}{ccc} Y^X \times X & \xrightarrow{ev} & Y \\ \phi \times 1 \uparrow & \nearrow e & \\ Z \times X & & \end{array}$$

commutes. Given a coalgebra X (corresponding to the space X) and a nilpotent algebra \mathcal{M} (corresponding to Y) we construct a nilpotent algebra $\mathcal{A}(\mathcal{M}, X)$ which corresponds to the function space Y^X ; and satisfies a dual algebraic universal property.

Unfortunately, the function space Y^X is in general not connected. This fact is reflected algebraically by the existence of elements of negative degree in $\mathcal{A}(\mathcal{M}, X)$. In effect, since the geometrical significance of these generators is not clear, we calculate the nilpotent model for a connected component of Y^X : given a map $f : X \rightarrow Y$; the f -component of Y^X satisfies the universal property but for any pointed space $(Z; *)$ and map $e : Z \times X \rightarrow Y$ whose restriction to $* \times X$ is simply f , then there is a unique pointed map $(Z, *) \xrightarrow{\phi} (Y^X, f)$ such that the above diagram $(*)$ commutes. In the algebraic situation the map $f : X \rightarrow Y$ corresponds to an algebra homomorphism $\rho : \mathcal{M} \rightarrow X^*$; we construct a nilpotent algebra $\mathcal{B}(\rho, X)$ which is a nilpotent model for the f -component of the function space Y^X , and which satisfies an analogous universal property. The essential ingredient in the proof that $\mathcal{B}(\rho, X)$ is indeed a nilpotent model for the f -component of Y^X is careful study of the dependence of the algebra $\mathcal{B}(\rho, X)$ on a change of X or \mathcal{M} by a map inducing an isomorphism on (co)homology. It is this algebraic study that we present here.

0. NOTATION .

All algebras, coalgebras, etc. will be over a field k of characteristic 0. We abbreviate commutative differential graded algebra by CDGA and cocommutative differential graded coalgebra by CDGC. (CDGA's are not necessarily positively graded: $A = (A^p)_{p \in \mathbb{Z}}$ with $d : A^p \rightarrow A^{p+1}$. On the other hand a CDGC is positively graded: $C = (C_p)_{p \geq 0}$ with $\partial : C_p \rightarrow C_{p-1}$. For convenience we raise degrees by $C^p = C_{-p}$ so that $C = (C^p)_{p \leq 0}$ is negatively graded and $\partial : C^p \rightarrow C^{p+1}$.) If A is CDGA and C a CDGC then $\text{Hom}(C, A)$ is a CDGA with the usual notations: $\text{Hom}^p(C, A) = \prod_1 \text{Hom}(C^i, A^{i+p})$, $d_{\text{Hom}}(\phi) = d_A \circ \phi + (-1)^{|\phi|+1} \phi \circ \partial_C$, $m_{\text{Hom}} = \text{Hom}(\Delta_C, m_A)$. $\text{Hom}(C, k)$ is denoted C^* .

The free CGA on a graded vector space Q is denoted ΛQ .

A CDGA \mathcal{M} is *nilpotent* if \mathcal{M} is free as a CGA ($\mathcal{M} \approx \Lambda Q_{\mathcal{M}}$) and the space of generators $Q_{\mathcal{M}}$ has a well-ordered basis $\{x_{\alpha}\}$ such that dx_{α} is a polynomial in the x_{β} with $\beta < \alpha$.

A CDGA or CDGC - map $f : A \rightarrow B$ is called a *quasi-isomorphism* if $H(f) : H(A) \xrightarrow{\cong} H(B)$ is an isomorphism.

1. THE MODEL FOR A FUNCTION SPACE.

Suppose X is a CDGC and $\mathcal{M} = \Lambda Q_{\mathcal{M}}$ a nilpotent CDGA (with $Q_{\mathcal{M}}$ strictly positively graded). Then there is a CDGA $\mathcal{A} = \mathcal{A}(\mathcal{M}, X)$ and a morphism

$$\varepsilon : \mathcal{M} \rightarrow \text{Hom}(X, \mathcal{A})$$

with the universal property that for any CDGA Z and map $e : \mathcal{M} \rightarrow \text{Hom}(X, Z)$ there is a unique map $\mathcal{A} \xrightarrow{\phi} Z$ such that the diagram

commutes. In fact, let $\mathcal{A} = \Lambda(Q_{\mathcal{M}} \otimes X)$ as a CGA. Define the map ε on generators $Q_{\mathcal{M}}$ by

$$\varepsilon(y)(x) = y \otimes x, \quad y \in Q_{\mathcal{M}}, \quad x \in X.$$

The differential in \mathcal{A} is chosen precisely so that ϵ is a map of CDGA's : $\epsilon \circ d_{\mathcal{M}} = d_{\text{Hom}} \circ \epsilon$ forces the definition

$$d_{\mathcal{A}}(y, \theta_X) = \epsilon(d_{\mathcal{M}} y) (x) + (-1)^{|y|} \epsilon(y) (\partial_X x).$$

This differential is extended to a degree λ derivation in \mathcal{A} : it is trivial to check that $d_{\mathcal{A}} \circ d_{\mathcal{A}} = 0$ and the universal property is satisfied.

1.1. REMARKS. 1. In general \mathcal{A} need not be positively graded (since X is negatively graded).

2. \mathcal{A} is nilpotent.

Now suppose $\rho: \mathcal{M} \rightarrow X^*$ is a CDGA map. By the universal property for ϵ , there is a unique augmentation

$$ev_{\rho}: \mathcal{A}(\mathcal{M}, X) \rightarrow k$$

such that the diagram

$$\begin{array}{ccc} \mathcal{M} & \xrightarrow{\epsilon} & \text{Hom}(X, \mathcal{A}) \\ \rho \downarrow & & \downarrow \text{Hom}(X, ev_{\rho}) \\ X^* & \xlongequal{\quad} & \text{Hom}(X, k) \end{array}$$

commutes. Let $I_{\rho} \subset \mathcal{A}$ be the ideal generated by $\mathcal{A}^{<0}$ (the elements of negative degree), $\mathcal{A}^0 \cap \text{Ker } ev_{\rho}$, and $d_{\mathcal{A}}(\mathcal{A}^0 \cap \text{Ker } ev_{\rho})$. Note that I_{ρ} is $d_{\mathcal{A}}$ -stable : $d_{\mathcal{A}}(\mathcal{A}^{<-1}) \subset \mathcal{A}^{<0}$, and $d_{\mathcal{A}}(\mathcal{A}^{-1}) \subset \mathcal{A}^0 \cap \text{ker } ev_{\rho}$ (since ev_{ρ} is a CDGA map).

1.2. DEFINITION . - $\mathcal{B}(\rho, X) = \mathcal{A}(\mathcal{M}, X) / I_{\rho}$.

1.3. LEMMA. - $\mathcal{B}(\rho, X)$ is a nilpotent CDGA.

PROOF. - To see that \mathcal{B} is free, we describe I_S differently. Let Q_A denote the space of generators for \mathcal{A} obtained by replacing each degree 0 generator ξ by $\xi - ev_p \xi$. (Note that we still have $\mathcal{A} \cong \mathcal{A} \wedge Q_A$ and this doesn't affect the nilpotence of \mathcal{A}). Let $K \subset Q_A$ be the graded subspace defined by

$$K^p = \begin{cases} Q_A^p & p \leq 0 \\ d_{Q_A}(Q_A) & p = 1 \\ 0 & p > 1 \end{cases}$$

and let $\Pi_Q : Q_A \rightarrow Q_A/K = Q_B$ be the projection. Then $\mathcal{B} \cong \mathcal{A} \wedge Q_B$ and under this isomorphism $\Pi : \mathcal{A} \rightarrow \mathcal{B}$ is just $\Lambda \Pi_Q : \Lambda Q_A \rightarrow \Lambda Q_B$. The nilpotence of \mathcal{B} is then an easy argument.

1.4 REMARK. - Let $\bar{e} = \text{Hom}(X, \Pi) \circ e : \mathcal{M} \rightarrow \text{Hom}(X, \mathcal{B})$. Then \bar{e} satisfies the following universal property for any augmented CDGA $Z \xrightarrow{\alpha} k$ and morphism $e : \mathcal{M} \rightarrow \text{Hom}(X, Z)$ such that the diagram

$$\begin{array}{ccc} \mathcal{M} & \xrightarrow{e} & \text{Hom}(X, Z) \\ & \searrow & \downarrow \text{Hom}(X, \alpha) \\ & & X^* \end{array}$$

commutes, there exists a unique map $\phi : \mathcal{B} \rightarrow Z$ such that

$$\begin{array}{ccc} \mathcal{M} & \xrightarrow{\bar{e}} & \text{Hom}(X, \mathcal{B}) \\ & \searrow e & \downarrow \text{Hom}(X, \phi) \\ & & \text{Hom}(X, Z) \end{array}$$

1.5 NATURALITY IN \mathcal{M} . Suppose X fixed and $\phi : \mathcal{M}_0 \rightarrow \mathcal{M}_1$ a map of nilpotent algebras. By the universal property there exists a unique map.

$$\phi_{\mathcal{A}} : \mathcal{A}(\mathcal{M}_0, X) \rightarrow \mathcal{A}(\mathcal{M}_1, X)$$

such that the diagram

$$\begin{array}{ccc} \mathcal{M}_0 & \xrightarrow{\varepsilon_0} & \text{Hom}(X, \mathcal{A}(\mathcal{M}_0, X)) \\ \downarrow \phi & & \downarrow \text{Hom}(X, \phi_{\mathcal{A}}) \\ \mathcal{M}_1 & \xrightarrow{\varepsilon_1} & \text{Hom}(X, \mathcal{A}(\mathcal{M}_1, X)) \end{array}$$

commutes.

Suppose now that $\mathcal{M}_1 \rightarrow X^*$. The universal property again implies that $\text{ev}_\rho \circ \phi_{\mathcal{A}} = \text{ev}_{\rho \circ \phi}$, so that $\phi_{\mathcal{A}}$ is augmentation preservity. It follows that $\phi_{\mathcal{A}}(I_{\rho \circ \phi}) \subset I_\rho$, and $\rho_{\mathcal{A}}$ therefore induces a CDGA map-

$$\phi_{\mathcal{B}} : \mathcal{B}(\rho \circ \phi, X) \rightarrow \mathcal{B}(\rho, X).$$

Clearly in the situation

$$\mathcal{M}_0 \xrightarrow{\phi} \mathcal{M}_1 \xrightarrow{\psi} \mathcal{M}_2 \rightarrow X^*$$

we obtain a commutative diagram

$$\begin{array}{ccc} \mathcal{B}(\rho \psi \phi, X) & \xrightarrow{\phi_{\mathcal{B}}} & \mathcal{B}(\rho \psi, X) \\ & \searrow (\psi \phi)_{\mathcal{B}} & \swarrow \psi_{\mathcal{B}} \\ & & \mathcal{B}(\rho, X) \end{array}$$

As an example, a pair of maps $M_0 \xrightarrow{\rho_0} X^* \xrightarrow{\rho_1} M_1$

induces

$$(\rho_0, \rho_1) : M_0 \otimes M_1 \xrightarrow{\rho_0 \otimes \rho_1} X^* \otimes X^* \xrightarrow{m} X^* .$$

Let $j_v : M_v \rightarrow M_0 \otimes M_1$, $v = 0, 1$, be the inclusions. The following result is immediate.

1.6. PROPOSITION. - *The maps*

$$(j_v)_{\mathcal{B}} : \mathcal{B}(\rho_v, X) \rightarrow \mathcal{B}((\rho_0, \rho_1), X), \quad v = 0, 1 ,$$

yield a natural isomorphism

$$((j_0)_{\mathcal{B}}, (j_1)_{\mathcal{B}}) : \mathcal{B}(\rho_0, X) \otimes \mathcal{B}(\rho_1, X) \xrightarrow{\cong} \mathcal{B}((\rho_0, \rho_1), X) .$$

1.7 NATURALITY IN X. - Suppose $f : X_0 \rightarrow X_1$ is a CDGC map and $M \xrightarrow{\rho} X_1^*$ a CDGA map. Just as above, the universal property implies that f induces

$$f_{\mathcal{B}} : \mathcal{B}(f^* \rho, X_0) \longrightarrow \mathcal{B}(\rho, X_1) .$$

Moreover, in the situation $X_0 \xrightarrow{f} X_1 \xrightarrow{g} X_2$, $M \xrightarrow{\rho} X_2^*$,

there is a commutative diagram

$$\begin{array}{ccc} \mathcal{B}(f^* g^* \rho, X_0) & \xrightarrow{f_{\mathcal{B}}} & \mathcal{B}(g^* \rho, X_1) \\ & \searrow (gf)_{\mathcal{B}} & \swarrow g_{\mathcal{B}} \\ & & \mathcal{B}(\rho, X_2) . \end{array}$$

1.8. HOMOTOPY INVARIANCE. The crucial results are the following.

THEOREM A. - *Given $M_0 \xrightarrow{\phi} M_1 \xrightarrow{\rho} X^*$ with ϕ a quasi-iso, then*

$$\phi_{\mathcal{B}} : \mathcal{B}(\rho \circ \phi, X) \longrightarrow \mathcal{B}(\rho, X)$$

is a quasi-iso.

THEOREM B. - Given $M \rightarrow X_1^*$ and a quasi-iso $X_0 \xrightarrow{f} X_1$, then
 $f_{\mathcal{B}} : \mathcal{B}(f^*\rho, X_0) \rightarrow \mathcal{B}(\rho, X_1)$ is a quasi-iso.

These theorems permit the following definition : if $f : X \rightarrow Y$ is a morphism of CDGC's, choose a minimal model $\rho : M \rightarrow Y^*$

1.9 DEFINITION. - $\mathcal{B}(Y^*, f) = \mathcal{B}(\rho, X)$.

It follows that the homotopy type of $\mathcal{B}(Y, f)$ depends only on the homotopy type of f .

2. PROOF OF THEOREM A.

We begin by studying a particularly easy special case of the theorem, which turns out to be the fundamental step in the proof (and at the same time gives a nice illustration of the construction of \mathcal{B}) : suppose $M_1 = \Lambda(x, dx)$, a contractible CDGA with $|x| = n > 0$. Then of course $k \xrightarrow{\phi} M_1$ is a quasi-iso. On the other hand $\mathcal{B}(k \rightarrow X^*, X) = k$, since $\mathcal{A}(k, X) = \Lambda X$ is negatively graded. If the theorem is to be true then for any map $\rho : M_1 = \Lambda(x, dx) \rightarrow X^*$ the algebra $\mathcal{B}(\rho, X)$ must be acyclic. In fact the theorem will follow immediately from this.

2.1. LEMMA. - Let $M = \Lambda(x, dx)$ with $|x| = n > 0$. Then for any X and any $\rho : M \rightarrow X^*$ the algebra $\mathcal{B}(\rho, X)$ is contractible.

PROOF. - Choose a basis ξ_{α}^m for each X^m . Then a basis for the generating space of $\mathcal{A} = \mathcal{A}(\rho, X)$ in dimension p is given by $\{x \otimes \xi_{\alpha}^{p-n}, dx \otimes \xi_{\beta}^{p-n-1}\}$. The differential $d_{\mathcal{A}}$ is entirely linear given by :

$$(2.2) \quad \begin{aligned} d_{\mathcal{B}} (x \otimes \xi_{\alpha}^{p-n}) &= dx \otimes \xi_{\alpha}^{p-n} + (-1)^n x \otimes \partial \xi_{\alpha}^{p-n}, \\ d_{\mathcal{B}} (dx \otimes \xi_{\beta}^{p-n-1}) &= (-1)^{n+1} dx \otimes \partial \xi_{\beta}^{p-n-1}. \end{aligned}$$

Notice that there are no generators in degrees $> n+1$ because X is negatively graded.

To obtain $Q_{\mathcal{B}}$ we first kill all of the negative generators. We next replace the degree 0 generators by constants.

$$\begin{aligned} x \otimes \xi_{\alpha}^{-n} &= \text{ev}_{\rho} (x \otimes \xi_{\alpha}^{-n}), \\ dx \otimes \xi_{\beta}^{-n-1} &= \text{ev}_{\rho} (dx \otimes \xi_{\beta}^{-n-1}) \end{aligned}$$

Finally we kill the differentials of the degree 0 generators :

$$\begin{aligned} dx \otimes \xi_{\alpha}^{-n} &= (-1)^{n+1} x \otimes \partial \xi_{\alpha}^{-n}, \\ dx \otimes \partial \xi_{\beta}^{-n-1} &= 0. \end{aligned}$$

It follows that the generators $Q_{\mathcal{B}}$ of \mathcal{B} are given by

$$Q_{\mathcal{B}}^p = \begin{cases} (x) \otimes X^{-n+1}, & p=1, \\ ((x) \otimes X^{p-n}) \otimes ((dx) \otimes X^{p-n-1}), & 1 < p < n+1, \\ (dx) \otimes X^0, & p = n+1, \\ 0, & \text{otherwise.} \end{cases}$$

Moreover the differential is still given by (2.2).

To show that \mathcal{B} is contractible we decompose the generators $Q_{\mathcal{B}}^p \approx R_{\mathcal{B}}^p \oplus S_{\mathcal{B}}^p$ so that

$$(3.2) \quad d_{\mathcal{B}} : R_{\mathcal{B}}^p \approx S_{\mathcal{B}}^{p+1}, \quad S_{\mathcal{B}}^p \rightarrow 0.$$

To do this we first decompose $X^r = B^r \oplus H^r \oplus C^r$ in such a way that

$$\partial : C^r \approx B^{r+1}, \quad B^r \rightarrow 0, \quad H^r \rightarrow 0.$$

(H^r is the (co)homology and B^r the (co)boundaries in degree r).

We then put

$$R_B^p = (x) \otimes X^{p-n}, \quad 1 \leq p \leq n,$$

$$S_B^p = (dx) \otimes X^{p-n-1}, \quad 2 \leq p \leq n+1.$$

The isomorphism

$$R_B^p \oplus S_B^p \xrightarrow{\cong} Q_B^p$$

is defined to be the inclusion on R_B^p , $(dx) \otimes B^{p-n-1}$ and $(dx) \otimes H^{p-n-1}$, while a generator $dx \otimes \zeta_\beta^{p-n-1}$ of $(dx) \otimes C^{p-n-1}$ is sent to

$$dx \otimes \zeta_\beta^{p-n-1} + (-1)^n x \otimes \partial \zeta_\beta^{p-n-1}.$$

Property (2.3) is now clear in virtue of the definition of the differential in (2.2).

2.4 COROLLARY. - For any contractible CDGA \mathcal{M} and any $\rho : \mathcal{M} \rightarrow X^*$, $\mathcal{B}(\rho, X)$ is contractible.

PROOF. - This follows from lemma 2.1 by taking direct limits.

2.5. COROLLARY. - Theorem A holds in the special case that $\mathcal{M}_1 = \mathcal{M}_0 \oplus b$ where b is contractible and $\rho : \mathcal{M}_0 \rightarrow \mathcal{M}_1$ is the inclusion.

PROOF. - Apply Prop. 1.6 and Cor. 2.4.

2.6. COROLLARY. - It is sufficient to prove theorem A in the case that \mathcal{M} is minimal.

PROOF. - By a theorem of Sullivan, any (positively graded) nilpotent algebra decomposes in the form $M_0 \approx \widehat{M}_0 \otimes b$, where \widehat{M}_0 is the minimal model of M_0 , b is contractible and the isomorphism is an isomorphism of CDGA's. Then apply Cor. 2.5 and naturality.

2.7. PROOF OF THEOREM A : By Cor. 2.6, we can assume that $\phi: M_0 \rightarrow M_1$ is a minimal model of M_1 . But $M_1 \approx M_0 \otimes b$, so uniqueness of minimal models gives a homotopy-commutative diagram

This means that there is a CDGA map $\phi: M_0^I \rightarrow M_1$ and a strictly commutative diagram

By Cor. 2.5 each of $j_{\mathcal{B}}$ and $(i_1)_{\mathcal{B}}$ is a quasi-iso, so by naturality $\bar{\phi}_{\mathcal{B}}$ is a quasi-iso. Again by Cor. 2.5 ; $(i_0)_{\mathcal{B}}$ is a quasi-iso, so naturality in the upper triangle finally implies that $\phi_{\mathcal{B}}$ is a quasi-iso.

2.8 COROLLARY. - If $\mathcal{M} \xrightarrow[\cdot f_1]{\rho_0} X^*$ are homotopic then $\mathcal{B}(\rho_0, X)$ and $\mathcal{B}(\rho_1, X)$ are homotopy equivalent.

yields quasi-isos $\mathcal{B}(\rho_0, X) \xrightarrow[(i_0)_{\mathcal{B}}]{} \mathcal{B}(\phi, X) \xleftarrow[(i_1)_{\mathcal{B}}]{} \mathcal{B}(\rho_1, X)$.

3. PROOF OF THEOREM B.

Recall that \mathcal{M} is a (pos.graded) nilpotent CDGA, $f : X_0 \rightarrow X_1$ a quasi-iso of CDGC's and $\rho : \mathcal{M} \rightarrow X_1^*$ a CDGA map. We must show that

$$f_{\mathcal{B}} : \mathcal{B}(f \circ \rho, X_0) \longrightarrow \mathcal{B}(\rho, X_1)$$

is a quasi-iso. We give an outline of the proof here.

The idea is to use the nilpotence of \mathcal{M} to give an inductive proof. Choose a basis $\{y_\alpha\}$ for the generators $Q_{\mathcal{M}}$ of \mathcal{M} such that $d_{\mathcal{M}}(y_\alpha) \in \mathcal{M}_{<\alpha}$, the sub-DGA generated by $\{y_\beta \mid \beta < \alpha\}$. Using $\mathcal{M}_{\leq \alpha} \hookrightarrow \mathcal{M} \longrightarrow X_1$ we construct CDGA's $(\mathcal{B}_0)_{\leq \alpha}$ and $(\mathcal{B}_1)_{\leq \alpha}$ with f inducing

$$(f_{\mathcal{B}})_{\leq \alpha} : (\mathcal{B}_0)_{\leq \alpha} \rightarrow (\mathcal{B}_1)_{\leq \alpha}.$$

We prove by induction on α that $(f_{\mathcal{B}})_{\leq \alpha}$ is a quasi-iso.

The first step is to decompose the generators $(Q_{\mathcal{M}})_{\leq \alpha} \otimes X_i$ as $((Q_{\mathcal{M}})_{<\alpha} \otimes X_i) \oplus ((y_\alpha) \otimes X_i)$. The next step is to decompose X_0 and X_1 in the form $H_i \oplus B_i \oplus C_i$ (as in lemme 2.1) so that the induced map $H_0 \rightarrow H_1$ is simply $H(f) : H(X_0) \xrightarrow{\approx} H(X_1)$. Just as in lemme 2.1, this leads to a decomposition

$$(\mathcal{B}_i)_{<\alpha} \simeq (\mathcal{B}_i)_{<\alpha} \otimes \Lambda R_i \otimes \Lambda S_i, \quad i = 0, 1,$$

where, denoting $|y_\alpha| = n$,

$$R_i^p = (y_\alpha) \otimes H_i^{-n+p}, \quad p \geq 1,$$

$$S_i^p = \begin{cases} (y_\alpha) \otimes C_i^{-n+1}, & p = 1, \\ (y_\alpha) \otimes B_i^{-n+p} \oplus (y_\alpha) \otimes C_i^{-n+p}, & p > 1. \end{cases}$$

With these identifications $(f_{\mathcal{B}})_{<\alpha}$ is of the form

$$(f_{\mathcal{B}})_{<\alpha} \otimes \Lambda H(f) \otimes \phi : (\mathcal{B}_0)_{<\alpha} \otimes \Lambda R_0 \otimes \Lambda S_0$$

↓

$$(\mathcal{B}_1)_{<\alpha} \otimes \Lambda R_1 \otimes \Lambda S_1.$$

Each ΛS_i is evidently acyclic, while $\Lambda H(f) : \Lambda R_0 \xrightarrow{\cong} \Lambda R_1$ is an isomorphism and, by the inductive hypothesis,

$$(f_{\mathcal{B}})_{<\alpha} : (\mathcal{B}_0)_{<\alpha} \longrightarrow (\mathcal{B}_1)_{<\alpha}$$

is a quasi-iso. It follows easily that $(f_{\mathcal{B}})_{\leq \alpha}$ is a quasi-iso, and this completes the induction.
