# ON THE OBSTRUCTION GROUP IN HOMOLOGY SURGERY 

by Pierre VOGEL

## o. Introduction

The theory of homology surgery has been introduced by Cappell and Shaneson [r]. This theory plays an important role in the theory of knots and codimension 2 embeddings.

Let ( $\mathrm{X}, \partial \mathrm{X}$ ) be a pair of finite complexes and $f$ be a normal map from the normal bundle of a (Top, PL or Diff)-manifold V to a (Top, PL or Diff)-bundle over X and let $\mathbf{M}$ be a $\mathbf{Z}\left[\pi_{1} \mathrm{X}\right]$-module. The problem of homology surgery is to determine the obstruction to the existence of a normal cobordism, constant over $\partial \mathrm{X}$, from $f$ to an M-homology equivalence. Clearly we must suppose that $f$ induces an M-homology equivalence from $\partial \mathrm{V}$ to $\partial \mathrm{X}$ and that the cap-product by $f_{*}[\mathrm{~V}]$ is an isomorphism from $\mathrm{H}^{*}(\mathrm{X}, \partial \mathrm{X} ; \mathrm{M})$ to $\mathrm{H}_{n-*}\left(\mathrm{X} ; \mathrm{M}^{w}\right), w$ being the first Stiefel-Whitney class of the bundle over X.

If $\mathbf{M}=A$ is a quotient ring with involution of $\mathbf{Z}\left[\pi_{1} \mathbf{X}\right]=\mathbf{Z} \pi$, Cappell and Shaneson have solved the problem and have constructed an obstruction group $\Gamma_{n}(\mathbf{Z} \pi \rightarrow A)$ defined in terms of algebraic L-theory.

In many cases, this group was known to be the $\mathrm{L}_{n}$-group of some ring $\Lambda$. For example, if there exists a classical localization $S^{-1} \mathbf{Z} \pi$ of $\mathbf{Z} \pi$, where $S$ is the multiplicative subset $\mathbf{I}+\operatorname{ker}(\mathbf{Z} \pi \rightarrow \mathbf{A})$, Smith [7] has proved that $\Gamma_{n}\left(\mathbf{Z}_{\pi} \rightarrow \mathbf{A}\right)$ is the group $\mathrm{L}_{n}\left(\mathrm{~S}^{-1} \mathbf{Z} \pi\right)$. An other example is given by Hausmann [3] who proves that $\Gamma_{n}(\mathbf{Z} \pi \rightarrow \mathbf{Z}[\pi / N])$ is the group $\mathrm{L}_{n}(\mathbf{Z}[\pi / \mathrm{N}])$ if N is a locally perfect normal subgroup of $\pi$.

My purpose is to show that the homology surgery is possible in a more general situation and that the obstruction group is always the $L_{n}$-group of a ring with involution $\Lambda$ endowed with a subgroup of $\widetilde{\mathrm{K}}_{1}(\Lambda)$.

For example, suppose that $\mathbf{Z} \pi \rightarrow \mathrm{A}$ is a morphism of rings with involution (the involution of $\mathbf{Z} \pi$ is induced by $w$ ). Then we have a diagram of rings with involution

well defined by the following properties:
i) For any matrix $u$ with entries in $\mathbf{Z} \pi$, if $u \otimes \mathrm{~A}$ is invertible then $u \otimes \Lambda$ is invertible too;
ii) $\Lambda$ is universal with respect to the property i).

Theorem. - Suppose the morphism $\Lambda \rightarrow \mathrm{A}$ is onto. Then any normal map $f$ over a $n$-dimensional A-Poincaré complex X which is an A-homology equivalence over $\partial \mathrm{X}$ determines an element $\sigma(f) \in \mathrm{L}_{n}^{h}(\Lambda)$, and, if $n \geq 5$, $f$ is normally cobordant to an A-homology equivalence if and only if $\sigma(f)$ vanishes.

Corollary. - If A is a quotient ring with involution of $\mathbf{Z} \pi$, the group $\Gamma_{n}^{h}(\mathbf{Z} \pi \rightarrow \mathrm{~A})$ is isomorphic to $\mathrm{L}_{n}^{h}(\Lambda)$.

Theorem. - Let $\mathrm{D}_{2 n}$ be the dihedral group of order $2 n$ ( $n$ odd) and $\mathrm{D}_{2 n} \rightarrow \mathbf{Z} / 2$ be the non zero homomorphism. Then we have the following isomorphism:

$$
\Gamma_{*}\left(\mathbf{Z} D_{2 n} \rightarrow \mathbf{Z}\right) \xrightarrow{\simeq} \Gamma_{*}(\mathbf{Z}[\mathbf{Z} / 2] \rightarrow \mathbf{Z}) \simeq \mathrm{L}_{*}^{h}(\Lambda),
$$

where $\Lambda$ is the pull back of rings:

## 1. Statement of the main results

(1.1) Let A be a ring with involution $a \mapsto \bar{a}$. If M is a left A-module, it can be given a right A-module structure, by setting

$$
m a=\bar{a} m, \quad \forall a \in \mathrm{~A}, \quad \forall m \in \mathrm{M} .
$$

Conversely any right A-module is a left A-module. From now on an A-module will mean a left or right A-module.

Denote by $\mathscr{C}(\mathrm{A})$ the category of $\mathbf{Z}$-graded complexes

$$
\ldots \rightarrow \mathrm{C}_{n+1} \rightarrow \mathrm{C}_{n} \rightarrow \mathrm{C}_{n-1} \rightarrow \ldots
$$

such that each $\mathrm{C}_{n}$ is a finitely generated free A-module with fixed (unordered) basis and $\bigoplus_{n} \mathrm{C}_{n}$ is finitely generated. Theses complexes will be called finite A-complexes.

We say that a sequence of finite A-complexes $0 \rightarrow \mathbf{C} \rightarrow \mathbf{C}^{\prime} \rightarrow \mathbf{C}^{\prime \prime} \rightarrow \mathbf{0}$ is $s$-exact if, for any $n$, the complex $\mathrm{o} \rightarrow \mathrm{C}_{n} \rightarrow \mathrm{C}_{n}^{\prime} \rightarrow \mathrm{C}_{n}^{\prime \prime} \rightarrow \mathrm{o}$ is acyclic with torsion o in $\widetilde{\mathrm{K}}_{1}(\mathrm{~A})$; see [4] and [9].

Definition (1.2). - A class $\mathscr{W} \subset \mathscr{C}(\mathrm{A})$ is exact if $\mathscr{W}$ contains any acyclic finite A-complex with torsion 0 , and if, for any $s$-exact sequence in $\mathscr{C}(\mathrm{A})$

$$
\mathrm{o} \rightarrow \mathrm{C} \rightarrow \mathrm{C}^{\prime} \rightarrow \mathrm{C}^{\prime \prime} \rightarrow \mathrm{o}
$$

one has the following property:
If two of the complexes $\mathbf{C}, \mathbf{C}^{\prime}, \mathbf{C}^{\prime \prime}$ lie in $\mathscr{W}$, then the third lies in $\mathscr{W}$ too.
Let G be a finite A-complex. Denote by $\hat{\mathrm{C}}_{n}$ the dual module $\operatorname{Hom}\left(\mathrm{C}_{-n}, \mathrm{~A}\right)$ endowed with the dual basis, and choose on $\widehat{\mathrm{C}}$ the differential so that the evaluation from $\widehat{\mathrm{C}} \otimes \mathrm{C}$ to A is a cocycle. So we get a new finite A-complex $\widehat{\mathrm{C}}$.

Definition (1.3). - An exact class $\mathscr{W} \subset \mathscr{C}(\mathrm{A})$ is called symmetric if, for any $\mathbf{C} \in \mathscr{W}$, $\widehat{\mathrm{C}}$ lies in $\mathscr{W}$.

Definition (1.4). - Let $\mathscr{W}$ be an exact class in $\mathscr{C}(\mathrm{A})$. A morphism $f$ in $\mathscr{C}(\mathrm{A})$ is a $\mathscr{W}$-equivalence if the mapping cone of $f$ is in $\mathscr{W}$.

Let $f$ be a map from a finite CW -complex X to a finite connected CW -complex Y , with fundamental group $\pi$, and let $\mathscr{W}$ be an exact class in $\mathscr{C}(\mathbf{Z} \pi)$ containing any acyclic finite $\mathbf{Z} \pi$-complex with torsion in the image of $\pi \rightarrow \widetilde{\mathrm{K}}_{1}(\mathbf{Z} \pi)$. Then $f$ is a $\mathscr{W}$-equivalence if the chain map $\mathrm{C}_{*}(\mathrm{X}, \mathbf{Z} \pi) \rightarrow \mathrm{C}_{*}(\mathrm{Y}, \mathbf{Z} \boldsymbol{\pi})$ is a $\mathscr{W}$-equivalence.

Example (1.5). - Let $\mathrm{A} \rightarrow \mathrm{B}$ be a ring homomorphism and $\beta$ be a subgroup of $\widetilde{\mathrm{K}}_{\mathbf{1}}(B)$. Let $\mathscr{W}$ be the class of finite A-complexes $C$ such that $\mathbf{C} \otimes_{A} B$ is acyclic with torsion in $\beta$. Then $\mathscr{W}$ is exact and the $\mathscr{W}$-equivalences are the $B$-homology equivalences with torsion in $\beta$.

If, in addition, $A \rightarrow B$ is a morphism of rings with involution and $\beta$ is stable under the involution, $\mathscr{W}$ is symmetric.

Example (1.6). - Let $M$ be an A-module. Then the class $\mathscr{W}$ of finite A-complexes C such that $\mathrm{H}_{*}(\mathrm{C}, \mathrm{M})$ (resp. $\mathrm{H}^{*}(\mathrm{C}, \mathrm{M})$ ) vanishes, is an exact class and the $\mathscr{W}$-equivalences are the M -homology (resp. M-cohomology) equivalences.

Notation (1.7). - Let $\mathscr{W}$ be an exact class in $\mathscr{C}(\mathrm{A})$. We denote by $\Sigma$ the set of matrices $u$ such that the direct sum of the complex $\ldots \rightarrow 0 \rightarrow \mathrm{~A}^{p} \xrightarrow{\boldsymbol{u}} \mathrm{~A}^{q} \rightarrow \mathrm{o} \rightarrow \ldots$ and its suspension is in $\mathscr{W}$.

In example ( $\mathrm{I} \cdot 5$ ), $\Sigma$ is the set of matrices $u$ with entries in $\mathbf{A}$ such that $u \otimes \mathbf{B}$ is invertible.

Proposition (1.8). - Let $\mathscr{W}$ be an exact class in $\mathscr{C}(\mathbf{A})$. Then there exists a ring homomorphism $\mathrm{A} \rightarrow \Lambda$ unique up to isomorphism, which is universal with respect to the following property: For any matrix $u \in \Sigma, u \otimes \Lambda$ is invertible.

If $\mathscr{W}$ is symmetric, $\mathrm{A} \rightarrow \Lambda$ is a morphism of rings with involution.
Actually, the ring $\Lambda$ is an inversive localization of A in the sense of Cohn [2].
Definition (1.9). - Let $\alpha$ be the subgroup of $\widetilde{\mathbf{K}}_{\mathbf{1}}(\Lambda)$ generated by the torsion of all complexes $\mathbf{C} \otimes \Lambda$, such that $\mathbf{C} \in \mathscr{W}$ and $\mathbf{C} \otimes \Lambda$ is acyclic. The pair ( $\Lambda, \alpha$ ) will be called the $\mathscr{W}$-localization of A.

Let $f$ be a normal map from the normal bundle of a compact $n$-dimensional (Top, PL or Diff)-manifold V to a (Top, PL or Diff)-bundle $\xi$ over a pair (X, $\partial \mathrm{X}$ ) of finite complexes. Suppose X is connected. The first Stiefel-Whitney class of $\xi$ induces an involution on the ring $\mathrm{A}=\mathbf{Z}\left[\pi_{1} \mathrm{X}\right]$.

Let $\mathscr{W}$ be an exact symmetric class in $\mathscr{C}(\mathrm{A})$ containing any acyclic complex with torsion in the image of $\pi_{1} \mathrm{X} \rightarrow \widetilde{\mathrm{K}}_{1}(\mathrm{~A})$.

Suppose we have the following properties:
i) $(\mathrm{X}, \partial \mathrm{X})$ is a $\mathscr{W}$-Poincaré complex; i.e. the cap-product by $f_{*}[\mathrm{~V}]$ is a $\mathscr{W}$-equivalence from $\mathrm{C}^{*}(\mathrm{X} ; \mathrm{A})$ to $\mathrm{C}_{*}(\mathrm{X}, \partial \mathrm{X} ; \mathrm{A})$.
ii) The restricted map $f: \partial \mathrm{V} \rightarrow \partial \mathrm{X}$ is a $\mathscr{W}$-equivalence.

Theorem (1.10). - Let $(\Lambda, \alpha)$ be the $\mathscr{W}$-localization of A. Suppose that any complex in $\mathscr{W}$ is $\Lambda$-acyclic. Then, the normal map $f$ determines a well-defined element $\sigma(f) \in \mathbf{L}_{n}^{\alpha}(\Lambda)$. And, if $n \geq 5$, $f$ is normally cobordant, rel the boundary, to a $\mathscr{W}$-equivalence if and only if $\sigma(f)$ vanishes.

Theorem (1.11). - With the same hypothesis as above, if $n \geq 6$, and X is a product $\mathrm{M} \times \mathrm{I}, \mathrm{M}$ being a (Top, PL or Diff)-manifold, any element of $\mathrm{L}_{n}^{\alpha}(\Lambda)$ is the obstruction $\sigma(f)$ of a normal map $f$ restricting to an isomorphism over $\mathrm{M} \times \mathrm{o} \cup \partial \mathrm{M} \times \mathrm{I}$.

Remark (1.12). - The condition of $\Lambda$-acyclicity of complexes in $\mathscr{W}$ is a very crucial point because, in the situation of (I.10), $\sigma(f)$ can be defined only if this condition is satisfied, or, more precisely, if the Poincaré duality on ( $\mathrm{X}, \partial \mathrm{X}$ ) is a $\Lambda$-homology equivalence and $f$ restricts to a $\Lambda$-homology equivalence on the boundaries.

On the other hand, this condition is not always satisfied. For example, if $\mathscr{W}$
is the class of finite $\mathbf{Z}\left[t, t^{-1}\right]$-complex with finite homology, the ring $\Lambda$ is $\mathbf{Z}\left[t, t^{-1}\right]$ and there exist many complexes in $\mathscr{W}$ which are not acyclic.

If the condition of $\Lambda$-acyclicity of complexes in $\mathscr{W}$ is not satisfied, denote by $\mathscr{W}^{\prime}$ the class of $\Lambda$-acyclic complexes in $\mathscr{W}$. Then theorems (i.io) and (i.ir) hold for the class $\mathscr{W}^{\prime}$. Now, the last problem is to compare the surgery problems corresponding to classes $\mathscr{W}$ and $\mathscr{W}^{\prime}$. But this question seems to be very difficult.

Let $\mathrm{A} \rightarrow \mathrm{B}$ be a ring homomorphism. Let $\Lambda$ be the inversive localization of A in the sense of Cohn [2] obtained by formal inversion of the matrices $u$ with entries in A such that $u \otimes \mathrm{~B}$ is invertible. The ring homomorphism $\mathrm{A} \rightarrow \Lambda$ will be called the localization of $\mathrm{A} \rightarrow \mathrm{B}$.

Theorem (1.13). - Let $\mathrm{A} \rightarrow \mathrm{B}$ be a ring homomorphism and $\beta$ be a subgroup of $\widetilde{\mathrm{K}}_{\mathbf{1}}(\mathrm{B})$. Denote by $\mathscr{W}$ the class of finite A -complexes which are B -acyclic with torsion in $\beta$, and by $(\Lambda, \alpha)$ the $\mathscr{W}$-localization of A.

Then $\mathrm{A} \rightarrow \Lambda$ is the localization of $\mathrm{A} \rightarrow \mathrm{B}$ and $\alpha$ is the inverse image of $\beta$ under the canonical morphism $\varepsilon: \Lambda \rightarrow$ B.

Moreover, if $\varepsilon$ is onto, any complex in $\mathscr{W}$ is $\Lambda$-acyclic.
Remark (1.14). - The ring $\Lambda$ and the group $L_{n}^{\alpha}(\Lambda)$ are difficult to compute, but we have some interesting results.

Let SCA be the set of elements in A invertible in B. Then, if there exists a classical localization $\mathrm{S}^{-1} \mathrm{~A}, \Lambda$ is the ring $\mathrm{S}^{-1} \mathrm{~A}$. This holds, for example, if A is commutative or if $\mathrm{A} \rightarrow \mathbf{B}$ is the ring homomorphism $\mathbf{Z} \pi \rightarrow \mathbf{Z} \pi^{\prime}$ induced by a group homomorphism $\pi \rightarrow \pi^{\prime}$ with finitely generated nilpotent kernel onto a finite extension of a polycyclic group [7].

An other example is the following (see theorem (9.7)): Let $\pi \rightarrow \mathbf{G}$ be a groupepimorphism with locally perfect kernel. Then the localization of $\mathbf{Z} \pi \rightarrow \mathbf{Z G}$ is $\mathbf{Z} \pi \rightarrow \mathbf{Z G}$ itself.

Anyway, the theorems (I.Io), (I.II), (I.13) imply that the obstruction groups $\Gamma_{n}(\mathrm{~A} \rightarrow \mathrm{~B})$ of Cappell and Shaneson [ I$]$ are always the $\mathrm{L}_{n}$-groups of $\Lambda$ (endowed with a subgroup of $\left.\widetilde{\mathrm{K}}_{1}(\Lambda)\right)$, at least when the theory of Cappell and Shaneson holds, i.e. when $\mathrm{A} \rightarrow \mathrm{B}$ is locally epic. This was already proved in some particular cases by Cappell and Shaneson [r], Smith [7], Hausmann [3] and the author [8].

Nevertheless the condition of surjectivity of $\Lambda \rightarrow B$ holds in many other cases.
Proposition (1.15). - Let $\mathrm{A} \rightarrow \mathrm{B}$ be a ring homomorphism and $\mathrm{A} \rightarrow \Lambda$ be the localization of $\mathrm{A} \rightarrow \mathrm{B}$. Let $\mathrm{B}_{0} \subset \mathrm{~B}_{1} \subset \mathrm{~B}_{2} \subset \ldots$ be subrings of B defined by:
i) $\mathrm{B}_{0}$ is the image of $\mathrm{A} \rightarrow \mathrm{B}$;
ii) For any $n \geq 0, \mathrm{~B}_{n+1}$ is generated by $\mathrm{B}_{n}$ and the inverses of the units of B contained in $\mathrm{B}_{n}$.

Then, the image of $\Lambda \rightarrow \mathbf{B}$ contains all the rings $\mathbf{B}_{n}$. Therefore, if $\mathbf{B}$ is the union of the rings $\mathrm{B}_{n}$, the morphism $\Lambda \rightarrow \mathrm{B}$ is onto and the theorems (1.10), (I.II), (I.I3) hold.

In fact, the image of $\Lambda \rightarrow B$ can be strictly greater than the union of the rings $B_{n}$.
Example (1.16). - Let F be the free group with $p$ generators, $p>1$, and let $A$ be the group ring $\mathbf{Z}[F]$. Let $\mathscr{W}$ be the class of finite A-complexes $C$ such that $H_{*}(\mathbf{C})$ is finitely generated over $\mathbf{Z}$ and let $(\Lambda, \alpha)$ be the $\mathscr{W}$-localization of $A$. Then the localization of $A \rightarrow \Lambda$ is $A \rightarrow \Lambda$ and the morphism $\Lambda \rightarrow \Lambda$ is the identity. One can prove that any square matrix with entries in A which is invertible in $\Lambda$, is invertible in $A$; hence $B_{n}=A$ for all $n$, but $A \rightarrow \Lambda$ is not surjective!

Remark (1.17). - Let $A \rightarrow B$ be a ring homomorphism and $\beta$ be a subgroup of $\widetilde{\mathrm{K}}_{1}(\mathrm{~B})$. Denote by $\mathscr{W}$ the class of finite A-complexes which are B-acyclic with torsion in $\beta$ and by $(\Lambda, \alpha)$ the $\mathscr{W}$-localization of $A$.

If the morphism $\Lambda \rightarrow B$ is not onto, the condition of $\Lambda$-acyclicity of complexes in $\mathscr{W}$ is not always satisfied.

For example, this condition holds if $\mathbf{A} \rightarrow \mathbf{B}$ is the ring homomorphism $\mathbf{Z} \rightarrow \mathbf{R}$, but it does not hold if $A$ is the ring $\mathbf{Z}\left[t, t^{-1}\right]$ and $B$ is the product of the localizations of $A$ with respect to the non zero principal prime ideals.

## 2. A first homology surgery obstruction group

In a first step, we will construct a surgery obstruction group $\Gamma_{n}(A, \mathscr{W})$ which looks like the group $\Gamma_{n}(\mathrm{~A} \rightarrow \mathrm{~B})$ constructed by Ranicki [5], but from a dual point of view.

Throughout sections 2 and 3 we assume that $A$ is a ring with involution and that $\mathscr{W}$ is an exact symetric class in $\mathscr{C}(\mathrm{A})$ (see (1.2) and (1.3)).

If $G$ and $C^{\prime}$ are finite A-complexes, we denote by $\operatorname{Hom}\left(C, C^{\prime}\right)$ the set of A-homomorphisms from $\mathbf{C}$ to $\mathrm{C}^{\prime} ; \operatorname{Hom}\left(\mathbf{C}, \mathrm{C}^{\prime}\right)$ can be given a graded differential Z-module structure by setting:

$$
\begin{aligned}
& \partial^{0} f(x)=\partial^{0} f+\partial^{0} x, \quad \text { for any } f \in \operatorname{Hom}\left(\mathbf{C}, \mathbf{C}^{\prime}\right), x \in \mathbf{C} \\
& d(f(x))=(d f)(x)+(-\mathrm{I})^{\partial^{\circ} f} f(d x), \quad \text { for any } f \in \operatorname{Hom}\left(\mathbf{C}, \mathbf{C}^{\prime}\right), x \in \mathbf{C} .
\end{aligned}
$$

Moreover, by setting

$$
\hat{f}(u)=(-1)^{\partial^{\circ} \not \partial^{\circ} u} u \circ f, \quad \text { for any } f \in \operatorname{Hom}\left(\mathbf{C}, \mathbf{C}^{\prime}\right), u \in \hat{\mathbf{C}}^{\prime}
$$

we get a morphism $f \rightarrow \hat{f}$ from $\operatorname{Hom}\left(\mathrm{C}, \mathrm{C}^{\prime}\right)$ to $\operatorname{Hom}\left(\hat{\mathrm{C}}^{\prime}, \hat{\mathrm{C}}\right)$ which respects the degrees and the differentials.

Notation (2.1). - If $\mathbf{G}$ is a finite A-complex, we denote by $\mathrm{B}(\mathbf{C})$ the graded differential $\mathbf{Z}$-module $\operatorname{Hom}(\mathbf{C}, \widehat{\mathrm{C}})$. The composite map:

$$
\operatorname{Hom}(\mathbf{C}, \widehat{\mathrm{C}}) \rightarrow \operatorname{Hom}(\hat{\mathbf{C}}, \widehat{\mathrm{C}}) \xrightarrow{\sim} \operatorname{Hom}(\mathrm{C}, \widehat{\mathrm{C}})
$$

is an involution on $B(C)$ and $B(C)$ is a graded differential $\mathbf{Z}[\mathbf{Z} / 2]$-module.

Definition (2.2). - Let $\mathbf{C}$ be a finite A-complex. We use $Q_{n}(\mathbf{C})$ to denote the group $H_{n}(\mathbf{Z} / 2, B(\mathbf{C}))$. By a quadratic $n$-form over $\mathbf{C}$, we mean an element of $\mathbf{Q}_{n}(\mathbf{C})$ and by a quadratic n-complex we mean a pair $(\mathbf{C}, q), q \in Q_{n}(\mathbf{C})$.

Let $\mathbf{C} \rightarrow \mathbf{C}^{\prime}$ be an epimorphism of degree o between two finite A-complexes. We use $\mathbf{Q}_{n}\left(\mathbf{C} \rightarrow \mathbf{C}^{\prime}\right)$ to denote the group $H_{n}\left(\mathbf{Z} / 2, \mathbf{B}(\mathbf{C}) / \mathbf{B}\left(\mathbf{C}^{\prime}\right)\right)$. By a quadratic $n$-form over $\mathbf{C} \rightarrow \mathbf{C}^{\prime}$, we mean an element of $\mathbf{Q}_{n}\left(\mathbf{C} \rightarrow \mathbf{C}^{\prime}\right)$ and by a quadratic n-pair, we mean a pair $\left(\mathbf{C} \rightarrow \mathbf{C}^{\prime}, q\right), \quad q \in \mathbf{Q}_{n}\left(\mathbf{C} \rightarrow \mathbf{C}^{\prime}\right)$.

Definition (2.3). - Let (C, $q$ ) be a quadratic $n$-complex. We will say that $q$ or $(\mathrm{C}, q)$ is $\mathscr{W}$-non singular if the image of $q$ by the composite map

$$
\mathrm{H}_{n}(\mathbf{Z} / 2, \mathrm{~B}(\mathbf{C})) \xrightarrow{\text { transfer }} \mathrm{H}_{n}(\mathrm{I}, \mathrm{~B}(\mathbf{C})) \simeq \mathrm{H}_{n}(\mathrm{~B}(\mathbf{C}))
$$

is represented by a $\mathscr{W}$-equivalence from C to $\widehat{\mathrm{C}}$.
Let $\left(\mathbf{C} \rightarrow \mathbf{C}^{\prime}, q\right)$ be a quadratic $n$-pair. Let K be the kernel of $\mathbf{C} \rightarrow \mathbf{C}^{\prime}$. We will say that $q$ or $\left(\mathbf{C} \rightarrow \mathbf{C}^{\prime}, q\right)$ is $\mathscr{W}$-non singular if the image of $q$ by the composite map

$$
\mathrm{H}_{n}\left(\mathbf{Z} / 2, \mathbf{B}(\mathbf{C}) / \mathrm{B}\left(\mathbf{C}^{\prime}\right)\right) \xrightarrow{\text { transfer }} \mathrm{H}_{n}\left(\mathbf{B}(\mathbf{C}) / \mathrm{B}\left(\mathbf{C}^{\prime}\right)\right) \rightarrow \mathrm{H}_{n}(\operatorname{Hom}(\mathrm{~K}, \widehat{\mathrm{C}}))
$$

is represented by a $\mathscr{W}$-equivalence from K to $\widehat{\mathrm{C}}$.

Remark (2.4). - If C is zero except in dimension $-p$, a quadratic $2 p$-form over C is exactly a $(-\mathrm{I})^{p}$-quadratic from over $\mathrm{C}_{-p}$ in the sense of Wall [II].

Remark (2.5). - If $\mathscr{W}$ is the class of acyclic complexes with zero torsion, a $\mathscr{W}$-non singular quadratic $n$-form $q$ over a finite A-complex C is an $n$-dimensional quadratic Poincaré structure on $\widehat{\mathbf{C}}$, in the sense of Ranicki [5], at least if $\widehat{\mathrm{C}}$ is (-I)-connected.

Definition (2.6). - We will denote by $\Gamma_{n}(\mathrm{~A}, \mathscr{W})$ the set of $\mathscr{W}$-non singular quadratic $n$-complexes subject to the following cobordism relation: $(\mathrm{C}, q)$ is cobordant to ( $\mathrm{C}^{\prime}, q^{\prime}$ ) if there exists a $\mathscr{W}$-non singular quadratic $(n+1)$-pair $\left(\Sigma \rightarrow \mathbf{C} \oplus \mathbf{C}^{\prime}, u\right)$ such that $\partial u=q \oplus-q^{\prime}$.

Let $W$ be the standard free resolution of the $\mathbf{Z}[\mathbf{Z} / 2]$-module $\mathbf{Z}$ :

$$
\mathbf{Z}[\mathbf{Z} / 2] e_{0} \stackrel{1-t}{\longleftarrow} \mathbf{Z}[\mathbf{Z} / 2] e_{1} \stackrel{1+t}{\leftarrow} \mathbf{Z}[\mathbf{Z} / 2] e_{2} \stackrel{1-t}{\longleftarrow} \ldots
$$

Then $Q_{n}(\mathbf{C})$ is the $n$-th homology group of $W \otimes_{\mathbf{Z} / 2} B(C)$.
Lemma (2.7). - Two $\mathscr{W}$-non singular quadratic $n$-complexes $(\mathbf{C}, q)$ and $\left(\mathbf{C}^{\prime}, q^{\prime}\right)$ are cobordant if and only if there exist two s-exact sequences

$$
\begin{aligned}
& \mathrm{o} \rightarrow \mathrm{~K} \rightarrow \Sigma \xrightarrow{\alpha} \mathrm{C} \rightarrow \mathrm{o} \\
& \mathrm{o} \rightarrow \mathrm{~K}^{\prime} \rightarrow \Sigma \xrightarrow{\alpha^{\prime}} \mathrm{C}^{\prime} \rightarrow \mathrm{o}
\end{aligned}
$$

and an element $e_{0} \otimes \psi_{0}+e_{1} \otimes \psi_{1}+\ldots$ in $\mathrm{W} \otimes_{\mathbf{z / 2}} \mathrm{B}(\Sigma)$ such that:
i) If $q$ and $q^{\prime}$ are the homology classes of $\varphi$ and $\varphi^{\prime}$, we have

$$
d\left(\sum e_{i} \otimes \psi_{i}\right)=\alpha^{*}(\varphi)-\alpha^{\prime *}\left(\varphi^{\prime}\right) ;
$$

ii) $\psi_{0}+\hat{\psi}_{0}$ induces a $\mathscr{W}$-equivalence from K to $\hat{\mathrm{K}}^{\prime}$.

Proof. - Suppose that $q$ and $q^{\prime}$ are represented by $\varphi \in \mathrm{W} \otimes_{\mathbf{z / 2}} \mathbf{B}(\mathbf{C})$ and $\varphi^{\prime} \in \mathrm{W} \otimes_{\mathbf{z} / 2} \mathbf{B}\left(\mathbf{C}^{\prime}\right)$. If $(\mathbf{C}, q)$ and ( $\left.\mathbf{C}^{\prime}, q^{\prime}\right)$ are cobordant, there exists a $s$-exact sequence

$$
\mathbf{0} \rightarrow \Sigma^{\prime} \rightarrow \Sigma^{\alpha \oplus \alpha^{\prime}} \mathbf{C} \oplus \mathbf{C}^{\prime} \rightarrow \mathbf{0}
$$

together with an element $\Sigma e_{i} \otimes \psi_{i} \in \mathrm{~W} \otimes \mathrm{~B}(\Sigma)$ such that:
(i) $d\left(\sum_{i} \otimes \psi_{i}\right)=\alpha^{*}(\varphi)-\alpha^{\prime *}\left(\varphi^{\prime}\right)$;
(ii) $\psi_{0}+\hat{\psi}_{0}$ induces a $\mathscr{W}$-equivalence from $\Sigma^{\prime}$ to $\hat{\Sigma}$.

Let K (respectively $\mathrm{K}^{\prime}$ ) be the kernel of $\alpha$ (respectively $\alpha^{\prime}$ ). We have a homotopy commutative diagram

where the lines are homotopy $s$-exact and $a$ and $b$ are induced by $\psi_{0}+\hat{\psi}_{0}$ and $c$ is induced by the transfer of $\varphi^{\prime}$.

Since $a$ and $c$ are $\mathscr{W}$-equivalences, $b$ is a $\mathscr{W}$-equivalence too and the first part of the lemma is proved.

Conversely, suppose we have two $s$-exact sequences

$$
\begin{aligned}
& \mathrm{o} \longrightarrow \mathrm{~K} \longrightarrow \Sigma \xrightarrow{\alpha} \mathrm{C} \longrightarrow 0 \\
& \mathrm{o} \longrightarrow \mathrm{~K}^{\prime} \longrightarrow \Sigma \xrightarrow{\alpha^{\prime}} \mathrm{C}^{\prime} \longrightarrow 0
\end{aligned}
$$

and an element $\Sigma_{e_{i}} \otimes \psi_{i}$ satisfying the conditions (i) and (ii) of the lemma. Up to simple homotopy type, we may suppose that $\alpha \oplus \alpha^{\prime}$ is onto with kernel $\Sigma^{\prime} \in \mathscr{C}(\mathrm{A})$. Then we have the homotopy commutative diagram (I) where $b$ and $c$ are $\mathscr{W}$-equivalences and $\psi_{0}+\hat{\psi}_{0}$ induces a $\mathscr{W}$-equivalence from $\Sigma^{\prime}$ to $\hat{\Sigma}$. Hence ( $\mathbf{C}, q$ ) and $\left(\mathbf{C}^{\prime}, q^{\prime}\right)$ are cobordant.

Lemma (2.8). - Let $(\mathbf{C}, q)$ be a $\mathscr{W}$-non singular quadratic n-complex and $f: \mathrm{C}^{\prime} \rightarrow \mathrm{C}$ be a $\mathscr{W}^{-}$-quivalence. Then $\left(\mathrm{C}^{\prime}, f^{*}(q)\right)$ is a $\mathscr{W}$-non singular quadratic $n$-complex cobordant to $(\mathbf{C}, q)$.

Proof. - We may suppose that $f$ is epic with kernel $\mathrm{K} \in \mathscr{C}(\mathrm{A})$. Then we have the $s$-exact sequences

$$
\begin{aligned}
& \mathrm{o} \longrightarrow \mathrm{~K} \longrightarrow \mathrm{C}^{\prime} \xrightarrow{t} \mathrm{C} \longrightarrow \mathrm{o} \\
& \mathrm{o} \longrightarrow \mathrm{o} \longrightarrow \mathrm{C}^{\prime} \xrightarrow{1} \mathrm{C}^{\prime} \longrightarrow \mathrm{o}
\end{aligned}
$$

and the result is an easy consequence of lemma (2.7).

## 3. Algebraic surgery

In order to kill the homology of a $\mathscr{W}$-non singular quadratic $n$-complex, in low dimension, we need the following:

Lemma (3.1). - Let $\mathrm{o} \rightarrow \mathrm{I} \xrightarrow{\alpha} \mathrm{C} \xrightarrow{\beta} \mathrm{J} \rightarrow \mathbf{0}$ be an s-exact sequence of finite A-complexes. Let $q$ be a $\mathscr{W}$-non singular quadratic $n$-form over C such that $\alpha^{*} q=0$. Then, $q$ is represented by a cycle $\Sigma e_{i} \otimes f_{i} \beta$.

Moreover if $q$ is represented by such a cycle, $(\mathbf{C}, q)$ is cobordant to a $\mathscr{W}$-non singular quadratic $n$-complex $\left(\mathbf{C}^{\prime}, q^{\prime}\right)$ where $\mathbf{C}^{\prime}$ is the mapping cone of $\hat{\alpha} f_{0}$ (the grading of $\mathbf{C}^{\prime}$ is chosen so that the map $\mathrm{C}^{\prime} \rightarrow \mathrm{J}$ has degree o).

Proof. - Consider the following exact sequences of graded differential $\mathbf{Z}[\mathbf{Z} / 2]$ modules:

$$
\begin{aligned}
& \mathrm{o} \rightarrow \mathrm{~B} \rightarrow \mathrm{~B}(\mathrm{C}) \xrightarrow{\alpha^{*}} \mathrm{~B}(\mathrm{I}) \rightarrow \mathrm{o} \\
& \operatorname{Hom}(\mathrm{C}, \widehat{\mathrm{~J}}) \oplus \operatorname{Hom}(\mathrm{J}, \widehat{\mathrm{C}}) \rightarrow \mathrm{B} \rightarrow \mathrm{o} .
\end{aligned}
$$

If $\alpha^{*} q$ is zero, $q$ is represented by a cycle in $\mathrm{W} \otimes_{\mathbf{Z} / 2} \mathrm{~B}$, and there exist morphisms $f_{i}^{\prime}$ and $f_{i}^{\prime \prime}$ in $\operatorname{Hom}(\mathrm{J}, \widehat{\mathrm{C}})$ such that $q$ is represented by

$$
\Sigma_{e_{i} \otimes} \otimes\left(f_{i}^{\prime} \beta+\widehat{\beta} \hat{f}_{i}^{\prime \prime}\right)
$$

Now we have

$$
d\left(e_{i+1} \otimes f_{i}^{\prime \prime} \beta\right)=e_{i} \otimes f_{i}^{\prime \prime} \beta+(-\mathrm{I})^{i+1} e_{i} \otimes \widehat{\beta} \hat{f}_{i}^{\prime \prime}+(-\mathrm{I})^{i+1} e_{i_{+1}} \otimes d f_{i}^{\prime \prime} \beta .
$$

Then there exist morphisms $f_{i} \in \operatorname{Hom}(\mathrm{~J}, \widehat{\mathrm{C}})$ such that $q$ is represented by $\Sigma_{e_{i}} \otimes f_{i} \beta$. Since $\Sigma e_{i} \otimes f_{i} \beta$ is a cycle, we have

$$
\forall i \geq 0, \quad(-1)^{i} d f_{i} \beta+f_{i+1} \beta+(-1)^{i+1} \hat{\beta} \hat{f}_{i+1}=0,
$$

whence

$$
d\left(\widehat{\alpha} f_{0}\right)=0, \quad \hat{\alpha} f_{i}=0, \quad \text { for any } i>0 .
$$

Let $\mathbf{C}^{\prime}$ be the mapping cone of $\hat{\alpha} f_{0}$. We have a split exact sequence

$$
\mathrm{o} \longrightarrow \hat{\mathrm{I}} \underset{r^{\prime}}{\stackrel{\alpha^{\prime}}{\leftrightarrows}} \mathrm{C}^{\prime} \xrightarrow{\beta^{\prime}} \mathrm{J} \longrightarrow \mathrm{o}
$$

such that

$$
\partial^{0} \alpha^{\prime}=-n-1, \quad \partial^{0} \beta^{\prime}=0, \quad d r^{\prime}=\hat{\alpha} f_{0} \beta^{\prime}, \quad r^{\prime} \alpha^{\prime}=\mathrm{I}
$$

and

$$
\mathrm{o} \rightarrow \mathrm{~S}^{-n-1} \hat{\mathrm{I}} \rightarrow \mathrm{C}^{\prime} \rightarrow \mathrm{J} \rightarrow \mathrm{o}
$$

is $s$-exact.
Let $\Sigma$ be the pull-back of C and $\mathrm{C}^{\prime}$ over J :

Let $r$ be a retraction of $\alpha$ and let $u$ be the element $e_{0} \otimes \hat{\gamma} \hat{r} r^{\prime} \gamma^{\prime} \in W \otimes_{\mathbf{z} / 2} \mathbf{B}(\Sigma)$. We have

$$
d u=e_{0} \otimes \hat{\gamma} d \hat{r} r^{\prime} \gamma^{\prime}+e_{0} \otimes \hat{\gamma} f_{0} \beta \gamma+e_{0} \otimes \hat{\gamma}(\hat{r} \hat{\alpha}-\mathrm{I}) f_{0} \beta^{\prime} \gamma^{\prime}
$$

and it is easy to see that $\gamma^{*}\left(\Sigma e_{i} \otimes f_{i} \beta\right)-d u$ has the form $\gamma^{\prime *}\left(\Sigma e_{i} \otimes \varphi_{i}^{\prime}\right), \quad \varphi_{i}^{\prime} \in \mathbf{B}\left(\mathbf{C}^{\prime}\right)$.
On the other hand, $\hat{\gamma} \gamma^{\prime} \gamma^{\prime}+\hat{\gamma}^{\prime} \hat{r}^{\prime} r \gamma$ induces the identity from the kernel of $\gamma^{\prime}$ to the dual of the kernel of $\gamma$. Then $\Sigma e_{i} \otimes \varphi_{i}^{\prime}$ represents a $\mathscr{W}$-non singular quadratic $n$-form $q^{\prime}$ over $\mathrm{C}^{\prime}$ and, by (2.7), $(\mathrm{C}, q)$ and $\left(\mathrm{C}^{\prime}, q^{\prime}\right)$ are cobordant.

Corollary (3.2). - Any $\mathscr{W}$-non singular quadratic n-complex is cobordant to a $\mathscr{W}$-non singular quadratic n-complex $(\mathbf{C}, q)$ such that $\mathbf{C}$ is $\left(\left[\frac{-n}{2}\right]-\mathrm{I}\right)$-connected.

Proof. - Just apply lemma (3.1), I being the $\left(\left[\frac{-n}{2}\right]\right.$ - I)-skeleton of the
lex.
Lemma (3.3). - Let $\mathrm{o} \rightarrow \mathrm{I} \xrightarrow{\alpha} \mathrm{C} \xrightarrow{\beta} \mathrm{J} \rightarrow \mathrm{o}$ be an s-exact sequence of finite A-complexes and $\gamma: \mathrm{J} \rightarrow \mathrm{K}$ be an epimorphism of degree o which respects the differentials. Let $q$ be a $\mathscr{W}$-non singular quadratic n-form over $\mathbf{C} \rightarrow \mathrm{K}$ such that $\alpha^{*} q=0$. Then $q$ is represented by $\Sigma e_{i} \otimes f_{i} \beta$.

Moreover, if $\mathrm{C}^{\prime}$ is the mapping cone of $\hat{\alpha} f_{0}$ (the grading being chosen as in lemma (3.1)), there exists a $\mathscr{W}$-non singular quadratic $n$-form $q^{\prime}$ over $\mathbf{C}^{\prime} \rightarrow \mathbf{K}$ such that $\partial q$ and $\partial q^{\prime}$ coincide in $\mathrm{Q}_{n-1}(\mathrm{~K})$.

Proof. - We have the following exact sequences of graded differential $\mathbf{Z}[\mathbf{Z} / 2]$ modules:

$$
\begin{aligned}
& 0 \rightarrow B \rightarrow B(C) / B(K) \xrightarrow{\alpha^{*}} B(I) \rightarrow 0 \\
& \operatorname{Hom}(C, \widehat{J}) \oplus \operatorname{Hom}(J, \widehat{C}) \rightarrow B \rightarrow 0 .
\end{aligned}
$$

Then, as in lemma (3.I), we show that $q$ is represented by an element $\Sigma e_{i} \otimes f_{i} \beta$ and we have

$$
d\left(\hat{\alpha} f_{0}\right)=0, \quad \hat{\alpha} f_{i}=0, \quad \text { for any } i>0 .
$$

Consider, as above, the diagram: $\mathbf{o} \rightarrow \hat{\mathbf{I}} \underset{r^{\prime}}{\stackrel{\alpha^{\prime}}{\rightleftarrows}} \mathbf{C}^{\prime} \xrightarrow{\beta^{\prime}} \mathrm{J} \rightarrow 0$ and let $s$ be a section of $\beta$. We have

$$
d s=\alpha \delta, \quad \delta \in \operatorname{Hom}(\mathrm{J}, \mathrm{I})
$$

It is not difficult to see that the element

$$
u=e_{0} \otimes \hat{\beta}^{\prime} \widehat{\delta} r^{\prime}+\Sigma e_{i} \otimes \hat{\beta}^{\prime} \hat{s} f_{i} \beta^{\prime}
$$

represents a quadratic $n$-form $q^{\prime}$ over $\mathrm{C}^{\prime} \rightarrow \mathrm{K}$ and that $\partial q$ and $\partial q^{\prime}$ coincide in $\mathrm{Q}_{n-1}(\mathrm{~K})$. Moreover, the transfer $\tilde{u}$ of $u$ is:

$$
\tilde{u}=\hat{\beta}^{\prime} \hat{\delta} r^{\prime}+(-\mathrm{I})^{n+1} \hat{r}^{\prime} \delta \beta^{\prime}+\hat{\beta}^{\prime} \hat{s} f_{0} \beta^{\prime}+\hat{\beta}^{\prime} \hat{f}_{0} s \beta^{\prime}
$$

and we have

$$
\tilde{u} \alpha^{\prime}=\hat{\beta}^{\prime} \hat{\delta} \quad \text { and } \quad \hat{\alpha}^{\prime} \tilde{u}=\delta \beta^{\prime} .
$$

Denote by $\overline{\mathrm{C}}, \overline{\mathrm{J}}, \overline{\mathrm{C}}^{\prime}$ the kernels of the morphisms $\mathrm{C} \rightarrow \mathrm{K}, \mathrm{J} \rightarrow \mathrm{K}$ and $\mathrm{C}^{\prime} \rightarrow \mathrm{K}$. We have the following commutative diagram:

and we obtain a $s$-exact sequence between the mapping cone of $\widehat{\delta}, \tilde{u}$ and $\delta$. Now the boundary of this $s$-exact sequence is homotopic to the morphism $(-1)^{n+1}\left(f_{0} \beta+\widehat{\beta} \hat{f}_{0}\right)$ from $\overline{\mathrm{C}}$ to $\hat{\mathrm{C}}$, which is a $\mathscr{W}$-equivalence. Then the mapping cone of $\tilde{u}: \overline{\mathrm{C}}^{\prime} \rightarrow \widehat{\mathrm{C}}^{\prime}$ is in $\mathscr{W}$ and $q^{\prime}$ is $\mathscr{W}$-non singular.

Corollary (3.4). - Let (C, q) be a $\mathscr{W}$-non singular quadratic $n$-complex cobordant to zero. Then there exists a $\mathscr{W}$-non singular quadratic $(n+1)$-pair $(\Sigma \rightarrow \mathrm{C}, u)$ such that $q$ is the boundary of $u$ and the kernel of $\mathrm{\Sigma} \rightarrow \mathrm{C}$ is $\left(\left[\frac{-n-\mathrm{I}}{2}\right]-\mathrm{I}\right)$-connected.

Proof. - If $(\mathbf{C}, q)$ is cobordant to zero, there exists a $\mathscr{W}$-non singular quadratic $(n+1)$-pair $\left(\Sigma^{\prime} \rightarrow \mathbf{C}, u^{\prime}\right)$ such that $q$ is the boundary of $u^{\prime}$. Then apply lemma (3.3), I being the $\left(\left[\frac{-n-1}{2}\right]-\mathrm{I}\right)$-skeleton of the kernel of $\Sigma^{\prime} \rightarrow \mathrm{C}$.

Now, if we want to kill the homology of a $\mathscr{W}$-non singular quadratic $n$-form beyond the middle dimension, we must suppose that $\mathscr{W}$ satisfies some other properties. Actually, it is useful to consider the new class $\mathscr{W}^{\prime}$ of all $\Lambda$-acyclic finite A-complexes.

Splitting lemma (3.5). - Let C be a complex in $\mathscr{W}^{\prime}$ and let $n$ be an integer. Then, there exist two finite A -complexes L and $\mathrm{L}^{\prime}$ concentrated in dimension $n$ and a $\mathscr{W}^{\prime}$-equivalence from L to the complex

$$
\mathrm{L}^{\prime} \oplus\left(\ldots \rightarrow \mathrm{C}_{n+1} \rightarrow \mathrm{C}_{n} \rightarrow \mathrm{o} \rightarrow \ldots\right)
$$

This lemma will be proved in § 7 .
Lemma (3.6). - Any $\mathscr{W}^{\prime}$-non singular quadratic $n$-complex is cobordant to a $\mathscr{W}^{\prime}$-non singular quadratic $n$-complex $(\mathbf{C}, q)$ where $\mathbf{C}$ vanishes except in dimension $\left[\frac{-n}{2}\right]\left(\right.$ and $\left[\frac{-n}{2}\right]+\mathrm{I}$
if $n$ is odd $)$.

Proof. - Let (C, $q$ ) be a $\mathscr{W}^{\prime}$-non singular quadratic $n$-complex. By corollary (3.2), we may as well suppose that $\mathrm{C}_{i}$ vanishes for $i<\left[\frac{-n}{2}\right]$.

Suppose $n=-2 p$. Since $(\mathrm{C}, q)$ is $\mathscr{W}^{\prime}$-non singular, we have the following complex in $\mathscr{W}^{\prime}$ :

$$
\ldots \rightarrow \mathrm{C}_{p+1} \rightarrow \mathrm{C}_{p} \rightarrow \hat{\mathrm{C}}_{p} \rightarrow \hat{\mathrm{C}}_{p+1} \rightarrow \ldots
$$

and, by splitting lemma (3.5), there exist two complexes $L$ and $L^{\prime}$ concentrated in dimension $p$ and a $\mathscr{W}^{\prime}$-equivalence

$$
f: \mathrm{L} \rightarrow \mathbf{G} \oplus \mathrm{~L}^{\prime} .
$$

Up to stabilization, we may suppose that $\mathrm{L}_{p}^{\prime}$ is even dimensional. Let $q^{\prime} \in \mathrm{Q}_{n}\left(\mathrm{~L}^{\prime}\right)$ be a standard hyperbolic structure on $\mathrm{L}_{p}^{\prime}$.

Then $(\mathbf{C}, q)$ is cobordant to $\left(\mathbf{C} \oplus \mathrm{L}^{\prime}, q \oplus q^{\prime}\right)$ and by lemma (2.8), $(\mathbf{C}, q)$ is cobordant to ( $\mathrm{L}, f^{*}\left(q \oplus q^{\prime}\right)$ ).

Suppose $n=-2 p-\mathrm{r}$. Since $(\mathbf{C}, q)$ is $\mathscr{W}^{\prime}$-non singular, we have the following complex in $\mathscr{W}^{\prime}$ :

$$
\ldots \rightarrow \mathrm{C}_{p+1} \rightarrow \mathrm{C}_{p} \oplus \widehat{\mathrm{C}}_{p} \rightarrow \widehat{\mathrm{C}}_{p+1} \rightarrow \ldots,
$$

and, by the splitting lemma (3.5), there exist two complexes $L$ and $L^{\prime}$ concentrated in dimension $p+1$ and a $\mathscr{W}^{\prime}$-equivalence

$$
\mathrm{L} \rightarrow \mathrm{~L}^{\prime} \oplus\left(\ldots \rightarrow \mathrm{C}_{p+2} \rightarrow \mathrm{C}_{p+1} \rightarrow 0 \ldots\right)
$$

We deduce a $\mathscr{W}^{\prime}$-equivalence

$$
f:\left(\ldots \rightarrow \mathrm{o} \rightarrow \mathrm{~L}_{p+1} \rightarrow \mathrm{C}_{p} \oplus \mathrm{~L}_{p+1}^{\prime} \rightarrow \mathrm{o} \ldots\right) \rightarrow \mathbf{C}
$$

and $(\mathrm{C}, q)$ is cobordant to $\left(\ldots \rightarrow 0 \rightarrow \mathrm{~L}_{p+1} \rightarrow \mathrm{C}_{p} \oplus \mathrm{~L}_{p+1}^{\prime} \rightarrow 0 \ldots, f^{*} q\right)$.
Lemma (3.7). - Let (C,q) be a $\mathscr{W}^{\prime}$-non singular quadratic (-2p)-complex such that $\mathrm{C}_{i}$ vanishes for $i \neq p$. Then $(\mathrm{C}, q)$ is cobordant to zero if and only if there exists a $\mathscr{W}^{\prime}$-non singular quadratic $(-2 p+1)$-pair $(\boldsymbol{\Sigma} \rightarrow \mathrm{C}, u)$ such that $q$ is the boundary of $u$ and $\Sigma_{i}$ vanishes for $i \neq p, p-\mathrm{I}$.

Proof. - Suppose ( $\mathbf{C}, q$ ) is cobordant to zero. By corollary (3.4), there exists a $\mathscr{W}^{\prime}$-non singular quadratic $(-2 p+1)$-pair $\left(\Sigma^{\prime} \rightarrow \mathrm{C}, u^{\prime}\right)$ such that $q$ is the boundary of $u^{\prime}$ and $\Sigma_{i}^{\prime}$ vanishes for $i<p-\mathrm{I}$. Let $\mathrm{K}^{\prime}$ be the kernel of $\Sigma \rightarrow \mathrm{C}$.

Since $u^{\prime}$ is $\mathscr{W}^{\prime}$-non singular, we have the following complex in $\mathscr{W}^{\prime}$ :

$$
\ldots \rightarrow \mathrm{K}_{p+1}^{\prime} \rightarrow \mathrm{K}_{p}^{\prime} \rightarrow \mathrm{K}_{p-1}^{\prime} \oplus \hat{\Sigma}_{p-1}^{\prime} \rightarrow \hat{\Sigma}_{p}^{\prime} \rightarrow \hat{\Sigma}_{p+1}^{\prime} \rightarrow \ldots
$$

and, by the splitting lemma (3.5), there exist two complexes $L, L^{\prime} \in \mathscr{C}(\mathrm{A})$ concentrated in dimension $p$ and a $\mathscr{W}^{\prime}$-equivalence

$$
\left(\ldots \rightarrow 0 \rightarrow \mathrm{~L}_{p} \rightarrow \mathrm{~K}_{p-1}^{\prime} \oplus \mathrm{L}_{p}^{\prime} \rightarrow 0 \rightarrow \ldots\right) \rightarrow \mathrm{K}^{\prime}
$$

Let K be the complex $\ldots \mathrm{o} \rightarrow \mathrm{L}_{p} \rightarrow \mathrm{~K}_{p-1}^{\prime} \oplus \mathrm{L}_{p}^{\prime} \rightarrow \mathrm{o} \rightarrow \ldots$. Since the $\mathscr{W}^{\prime}$-equivalence $\mathrm{K} \rightarrow \mathrm{K}^{\prime}$ is ( $p-\mathrm{I}$ )-connected, the boundary $\mathrm{C} \rightarrow \mathrm{K}^{\prime}$ lifts through K and we get a commutative diagram

where the lines are $s$-exact.
Then $\left(\Sigma \rightarrow \mathbf{C}, f^{*} u^{\prime}\right)$ is the desired quadratic pair.

Lemma (3.8). - Let ( $\mathrm{C}, q$ ) be a $\mathscr{W}^{\prime}$-non singular quadratic ( $-2 p-1$ )-form such that $\mathrm{C}_{i}$ vanishes for $i \neq p, p+\mathrm{I}$. Then $(\mathrm{C}, q)$ is cobordant to zero if and only if there exists a $\mathscr{W}^{\prime}$-non singular quadratic $(-2 p)$-pair $(\Sigma \rightarrow \mathrm{C}, u)$ such that $q$ is the boundary of $u$ and $\Sigma_{i} \rightarrow \mathrm{C}_{i}$ is a simple isomorphism for $i \neq p$.

Proof. - Suppose ( $\mathrm{C}, q$ ) is cobordant to zero. By corollary (3.4), there exists a $\mathscr{W}^{\prime}$-non singular quadratic $(-2 p)$-pair $\left(\Sigma^{\prime} \rightarrow \mathrm{C}, u^{\prime}\right)$ such that $q$ is the boundary of $u^{\prime}$ and $\Sigma_{i}^{\prime}$ vanishes for $i<p$.

Let $\mathrm{K}^{\prime}$ be the kernel of $\Sigma^{\prime} \rightarrow \mathrm{C}$. We have a complex in $\mathscr{W}^{\prime}$

$$
\ldots \rightarrow \Sigma_{p+1}^{\prime} \rightarrow \Sigma_{p}^{\prime} \rightarrow \hat{\mathrm{K}}_{p}^{\prime} \rightarrow \hat{\mathrm{K}}_{p+1}^{\prime} \rightarrow \ldots
$$

and, by the splitting lemma (3.5), there exist two complexes $L$ and $L^{\prime} \in \mathscr{C}(A)$ concentrated in dimension $p$ and a $\mathscr{W}^{\prime}$-equivalence

$$
f: \mathrm{L} \rightarrow \Sigma^{\prime} \oplus \mathrm{L}^{\prime}
$$

Up to stabilization, we may suppose that $\mathrm{L}_{p}^{\prime}$ is even dimensional. Let $v \in \mathbb{Q}_{-2 p}\left(\mathrm{~L}^{\prime}\right)$ be a standard hyperbolic structure on $\mathrm{L}_{p}^{\prime}$.

Let X be an acyclic finite A-complex with torsion zero concentrated in dimension $p-1, p, p+1$ and $\mathrm{X} \rightarrow \mathrm{C}$ be an epimorphism with kernel in $\mathscr{C}(\mathrm{A})$ such that $\mathrm{X}_{p+1} \rightarrow \mathrm{C}_{p+1}$ is an isomorphism. Let $\left(\Sigma^{\prime \prime} \rightarrow \mathbf{C}, u^{\prime \prime}\right)$ be the quadratic ( $-2 p$ )-pair defined by $\Sigma^{\prime \prime}=\mathrm{L} \oplus \mathrm{X}, u^{\prime \prime}=f^{*}\left(u^{\prime} \oplus v\right) \oplus \mathrm{o}$.

It is easy to see that $u^{\prime \prime}$ is $\mathscr{W}^{\prime}$-non singular and that $\partial u^{\prime \prime}=q$. Moreover the kernel $\mathrm{K}^{\prime \prime}$ of $\Sigma^{\prime \prime} \rightarrow \mathrm{C}$ is concentrated in dimension $p-1$ and $p$.

Now, by lemma (3.3), we can kill the $p-1$ skeleton of $K^{\prime \prime}$ by surgery and we get a $\mathscr{W}^{\prime}$-non singular $(-2 p)$-pair $(\Sigma \rightarrow \mathbf{C}, u)$ such that $\partial u=q$ and the kernel of $\Sigma \rightarrow \mathbf{C}$ vanishes except in dimension $p$.

Now, with the above lemmas, it is possible to give an interpretation of $\Gamma_{n}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right)$ in term of special forms in the sense of Wall [ro] and Cappell and Shaneson [r].

Definition (3.9). - Let $\eta= \pm \mathrm{I}$ and $\mathrm{I}_{\eta}=\{a-\eta \bar{a}, a \in \mathrm{~A}\}$. A $\mathscr{W}^{\prime}$-special $\eta$-form is a triple $(H, \lambda, \mu)$ where $H$ is a finitely generated free A-module, $\lambda$ a $\mathbf{Z}$-bilinear map from $H \otimes_{z} H$ to $A$ and $\mu$ a map from $H$ to $A / I_{\eta}$, and satisfying the following conditions:
$Q_{1}$
$\lambda(a x, y b)=a \lambda(x, y) b, \quad \forall x, y \in \mathrm{H}, \forall a, b \in \mathrm{~A}$
$\mathrm{Q}_{2}$
$\lambda(x, y)=\eta \overline{\lambda(y, x)}, \quad \forall x, y \in \mathrm{H}$
Q。
$\mu(x)+\eta \mu(y)=\lambda(x, y), \quad \forall x, y \in \mathrm{H}$
Q $_{4} \quad \mu(x+y) \equiv \mu(x)+\mu(y)+\lambda(x, y) \bmod \mathrm{I}_{n}, \quad \forall x, y \in \mathrm{H}$
$\mathrm{Q}_{5} \quad \mu(x a)=\bar{a} \mu(x) a, \quad \forall x \in \mathrm{H}, \forall a \in \mathrm{~A}$
Q6 the morphism $\tilde{\lambda}$ induced by $\lambda$ is a $\Lambda$-isomorphism (i.e. $\tilde{\lambda} \otimes \Lambda$ is an isomorphism).

Definition (3.10). - Let $(H, \lambda, \mu)$ be a $\mathscr{W}^{\prime}$-special $\eta$-form. A $\mathscr{W}^{\prime}$-subkernel of $(H, \lambda, \mu)$ is a free A-module $K$ endowed with a morphism $f: \mathrm{K} \rightarrow \mathrm{H}$ satisfying the following conditions:
$\mathrm{S}_{1}$
$\mathrm{S}_{2} \quad$ the following complex lies in $\mathscr{W}^{\prime}: \mathrm{o} \rightarrow \mathrm{K} \xrightarrow{f} \mathrm{H} \xrightarrow{\hat{f} \tilde{\lambda}} \hat{\mathrm{~K}} \rightarrow \mathrm{o}$.
(3.11) Let $\eta=(-1)^{p}$ and let $(H, \lambda, \mu)$ be a $\mathscr{W}^{\prime}$-special $\eta$-form. Since $H$ is free, there exists a map $\varphi_{0}: H \rightarrow \hat{H}$ such that

$$
\begin{array}{ll}
\lambda(x, y)=\varphi_{0}(x)(y)+\eta \overline{\varphi_{0}(y)(x)}, & \forall x, y \in \mathrm{H} \\
\mu(x) \equiv \varphi_{0}(x)(x) \bmod \mathrm{I}_{n}, & \forall x \in \mathrm{H} .
\end{array}
$$

And, if $\varphi_{0}$ and $\varphi_{0}^{\prime}$ are such two maps, $\varphi_{0}-\varphi_{0}^{\prime}$ has the form $\psi-\eta \hat{\psi}$.
Choose a basis for $H$ and denote by $H_{*}$ the finite A-complex defined by

$$
\mathrm{H}_{i}= \begin{cases}\mathrm{H}, & i=-p \\ \mathrm{o}, & i \neq-p\end{cases}
$$

Then $e_{0} \otimes \varphi_{0}$ represents a $\mathscr{W}^{\prime}$-non singular quadratic $2 p$-form $q$ over $\mathrm{H}_{*}$ and the cobordism class of $\left(\mathrm{H}_{*}, q\right)$ is a well defined element $\omega(\mathrm{H}, \lambda, \mu) \in \Gamma_{2 p}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right)$.
(3.12) Let $\eta=(-\mathrm{I})^{p}$ and let $f: \mathrm{K} \rightarrow \mathrm{B} \oplus \hat{\mathrm{B}}$ be a $\mathscr{W}^{\prime}$-subkernel of a standard $\eta$-kernel $\mathbf{B} \oplus \hat{\mathbf{B}} \quad(\mathbf{B}$ is a finitely generated free A-module). The map $f$ is induced by maps $d: \mathbf{K} \rightarrow \mathbf{B}$ and $\varphi_{0}: \mathbf{K} \rightarrow \hat{\mathbf{B}}$. Since the quadratic form is trivial over K , there exists a map $\varphi_{1}: \mathbf{K} \rightarrow \widehat{\mathbf{K}}$ such that $\hat{\varphi}_{0} \circ d=\varphi_{1}-(-\mathrm{I})^{p} \hat{\varphi}_{1}$. Choose basis for K and $B$. Let $\mathbf{C}$ be the $-p$-dimensional complex

$$
\ldots \rightarrow \mathrm{o} \rightarrow \mathrm{~K} \xrightarrow{d} \mathrm{~B} \rightarrow \mathrm{o} \rightarrow \ldots
$$

Let $\varphi_{0} \mid \mathbf{B}=\mathbf{o}$. We get two bilinear forms $\varphi_{0}$ and $\varphi_{1}$ on $\mathbf{C}$, and we have

$$
d \varphi_{0}=\varphi_{1}-\hat{\varphi}_{1} .
$$

Then, $e_{0} \otimes \varphi_{0}-e_{1} \otimes \varphi_{1}$ is a cycle in $\mathrm{W} \otimes_{\mathbf{z} / 2} \mathrm{~B}(\mathrm{C})$ inducing a quadratic $(2 p+1)$-form $q$ over C .

It is easy to see that $q$ is $\mathscr{W}^{\prime}$-non singular. We denote by $\omega(f) \in \Gamma_{2 p+1}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right)$ the cobordism class of $(\mathbf{C}, q)$. This element depends a priori on the choice of $\varphi_{1}$.

On the other hand, the tensorization by $\Lambda$ induces a map from $\Gamma_{n}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right)$ to $\Gamma_{n}\left(\Lambda, \mathscr{W}_{1}\right)$ where $\mathscr{W}_{1}$ is the class of finite acyclic $\Lambda$-complexes. But the group $\Gamma_{n}\left(\Lambda, \mathscr{W}_{1}\right)$ is isomorphic to $\mathrm{L}_{n}^{h}(\Lambda)$. Then we get a morphism $\varepsilon$ from $\Gamma_{n}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right)$ to $\mathrm{L}_{n}^{h}(\Lambda)$ and $\varepsilon \omega(f)$ is the class of $f \otimes \Lambda$ in $\mathrm{L}_{n}^{h}(\Lambda)$. We deduce that $\varepsilon \omega(f)$ does not depend on the choice of $\varphi_{1}$. But it will be proved in $\S 8$ that $\varepsilon$ is an isomorphism. Therefore $\omega(f)$ is well defined.

Proposition (3.13). - Any element of $\Gamma_{2 p}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right)$ has the form $\omega(\mathrm{H}, \lambda, \mu)$ for some $\mathscr{W}^{\prime}$-special (-1) ${ }^{p}$-form $(\mathrm{H}, \lambda, \mu)$ and any element of $\Gamma_{2 p+1}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right)$ has the form $\omega(f)$ for some $\mathscr{W}^{\prime}$-subkernel $f: \mathbf{K} \rightarrow \mathbf{B} \oplus \widehat{\mathbf{B}}$ of a standard $(-\mathrm{I})^{p}$-kernel $\mathbf{B} \oplus \hat{\mathrm{B}}$.

Proof. - In the even dimensional case, this is a trivial consequence of lemma (3.6).
In the odd dimensional case, we know by lemma (3.6) that any element of $\Gamma_{2 p+1}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right)$ is the cobordism class of a $\mathscr{W}^{\prime}$-non singular $2 p+\mathrm{I}$-complexes $(\mathrm{C}, q)$ where $\mathrm{C}_{i}$ vanishes for $i \neq-p,-p-\mathrm{I}$. It is not difficult to see that $q$ is represented by $e_{0} \otimes \varphi_{0}+e_{1} \otimes \varphi_{1}$, where the morphism $\varphi_{0}$ is trivial over $\mathrm{C}_{-p-1}$. Then the cobordism class of $(\mathbf{C}, q)$ is $\omega(f)$ where $f$ is the map $d \oplus \varphi_{0}: \mathbf{C}_{-p} \rightarrow \mathbf{C}_{-p-1} \oplus \widehat{\mathrm{C}}_{-p-1}$.

Proposition (3.14). - Let $(\mathrm{H}, \lambda, \mu)$ be a $\mathscr{W}^{\prime}$-special (- I$)^{p}$-form. Then $\omega(\mathrm{H}, \lambda, \mu)$ is zero if and only if the direct sum of $(\mathrm{H}, \lambda, \mu)$ and a standard kernel has a $\mathscr{W}^{\prime}$-subkernel.

Proof. - Suppose that $(\mathrm{H}, \lambda, \mu)$ has a $\mathscr{W}^{\prime}$-subkernel $f: \mathrm{K} \rightarrow \mathrm{H}$. Consider the quadratic $2 p$-complex $\left(\mathrm{H}_{*}, q\right)$ constructed in (3.II). Choose a basis for K and denote by $\mathrm{K}_{*} \in \mathscr{C}(\mathrm{~A})$ the complex defined by

$$
\mathrm{K}_{i}= \begin{cases}\mathrm{K}, & i=-p \\ \mathrm{o}, & i \neq-p\end{cases}
$$

Let $\mathrm{K}_{*} \rightarrow \mathrm{H}_{*}^{\prime} \xrightarrow{g} \mathrm{H}_{*}$ be a factorization of $f$ such that $g$ is a simple homotopy equivalence and $\mathrm{K}_{*} \rightarrow \mathrm{H}_{*}^{\prime}$ is a monomorphism with free cokernel. After doing an algebraic surgery along $\mathrm{K}_{*} \rightarrow \mathrm{H}_{*}^{\prime}$, we show that $\left(\mathrm{H}_{*}^{\prime}, g^{*} q\right.$ ) is cobordant to $\left(\mathrm{H}_{*}^{\prime \prime}, q^{\prime \prime}\right)$ where $\mathrm{H}_{*}^{\prime \prime}$ has the simple homotopy type of

$$
\ldots \rightarrow \mathrm{o} \rightarrow \mathrm{~K} \rightarrow \mathrm{H} \rightarrow \hat{\mathrm{~K}} \rightarrow \mathrm{o} \rightarrow \ldots
$$

The complex $\mathrm{H}_{*}^{\prime \prime}$ is thus $\Lambda$-acyclic and $\left(\mathrm{H}_{*}, q\right)$ is cobordant to zero.

Now suppose that the direct sum of $(H, \lambda, \mu)$ and a standard kernel $H^{\prime}$ has a $\mathscr{W}^{\prime}$-subkernel. We have

$$
\omega(H, \lambda, \mu)=\omega(H, \lambda, \mu)+\omega\left(H^{\prime}\right)=0 .
$$

Conversely suppose that $\omega(\mathrm{H}, \lambda, \mu)$ vanishes. By lemma (3.7), there exists a $\mathscr{W}^{\prime}$-non singular quadratic ( $2 p+\mathrm{r}$ ) -pair $\left(\Sigma \xrightarrow{\alpha} \mathrm{H}_{*}, u\right)$ such that $q$ is the boundary of $u$ and $\Sigma_{i}$ vanishes for $i \neq-p,-p-\mathrm{I}$.

The form $u$ can be represented by $e_{0} \otimes \psi_{0}+e_{1} \otimes \psi_{1}, \quad \psi_{0}$ vanishing on $\Sigma_{-p-1}$. Let K be the kernel of $\Sigma_{-p} \rightarrow \mathrm{H}$.

Since $u$ is $\mathscr{W}^{\prime}$-non singular, the following complex is $\Lambda$-acyclic:

$$
\mathbf{0} \longrightarrow \Sigma_{-p} \xrightarrow{d \oplus(-1)^{p} \psi_{0}} \Sigma_{-p-1} \oplus \hat{\Sigma}_{-p-1} \xrightarrow{\hat{\psi}_{0}+\hat{a}} \hat{\mathbf{K}} \longrightarrow \mathbf{0},
$$

and since $\tilde{\lambda}: H \rightarrow \hat{H}$ is a $\Lambda$-isomorphism, we deduce that

$$
\alpha \oplus d \oplus(-1)^{p} \psi_{0}: \Sigma_{-p} \rightarrow \mathrm{H} \oplus \Sigma_{-p-1} \oplus \hat{\Sigma}_{-p-1}
$$

is a $\mathscr{W}^{\prime}$-subkernel of the direct sum of $(H, \lambda, \mu)$ and the standard kernel $\Sigma_{-p-1} \oplus \hat{\Sigma}_{-p-1}$.
Proposition (3.15). - Let $f: \mathrm{K} \rightarrow \mathbf{B} \oplus \hat{\mathbf{B}}$ be a $\mathscr{W}^{\prime}$-subkernel of the standard (-1 $)^{p}$-kernel $\mathbf{B} \oplus \hat{\mathbf{B}}$. Then $\omega(f)$ is zero if and only if there exist a kernel $\mathbf{G} \oplus \hat{\mathbf{C}}$ endowed with its standard subkernel $g: \mathbf{C} \rightarrow \mathbf{C} \oplus \hat{\mathrm{C}}$ and an isometry $h$ of $\mathbf{B} \oplus \hat{\mathbf{B}} \oplus \mathbf{C} \oplus \hat{\mathrm{C}}$ leaving each element of $\mathbf{B} \oplus \hat{\mathrm{C}}$ fixed, such that the composite map

$$
\mathbf{K} \oplus \mathbf{G} \xrightarrow{h_{\circ}(f \oplus g)} \mathbf{B} \oplus \hat{\mathbf{B}} \oplus \mathbf{C} \oplus \hat{\mathbf{C}} \longrightarrow \mathbf{B} \oplus \hat{\mathrm{C}}
$$

is a $\Lambda$-isomorphism.
Proof. - Consider the " if" part first. If $g$ is the standard subkernel of $\mathbf{G} \oplus \widehat{\mathrm{C}}$, the complex associated to $g$ (see (3.12)) is acyclic and then $\omega(g)$ vanishes.

The complex associated to $f \oplus g$ is

$$
\mathrm{o} \rightarrow \mathrm{~K} \oplus \mathrm{C} \rightarrow \mathrm{~B} \oplus \mathrm{C} \rightarrow \mathrm{o} \rightarrow \ldots
$$

If we perform a surgery along $B$, we get a new complex

$$
\ldots \rightarrow \mathrm{K} \oplus \mathbf{C} \rightarrow \hat{\mathrm{~B}} \oplus \mathbf{C} \rightarrow \mathbf{o} \rightarrow \ldots
$$

and $\omega(f)$ is equal to $\omega\left(f^{\prime}\right), f^{\prime}$ being the new $\mathscr{W}^{\prime}$-subkernel

$$
\mathrm{K} \oplus \mathbf{\mathrm { C }} \xrightarrow{f \oplus g} \hat{\mathrm{~B}} \oplus \mathbf{C} \oplus(\widehat{\widehat{\mathrm{~B}} \oplus \mathbf{C}}) .
$$

It is easy to show that, for any isometry $h$ of $\hat{\mathbf{B}} \oplus \mathbf{G} \oplus \mathbf{B} \oplus \hat{\mathrm{C}}$ leaving each element of $\mathrm{B} \oplus \widehat{\mathrm{C}}$ fixed ( $h \in \mathrm{UU}_{r}(\mathrm{~A})$ with the notations of [io]), the two $\mathscr{W}^{\prime}$-subkernels $f^{\prime}$ and $h \circ f^{\prime}$ represent the same quadratic ( $2 p+1$ )-form over the same complex.

It suffices now to perform a surgery along $\hat{\mathbf{B}} \oplus \mathbf{C}$ to get a $\Lambda$-acyclic complex and $\omega(f)$ is zero.

Conversely, suppose $\omega(f)$ is zero. Let $\left(\mathbf{C}_{*}, q\right)$ be the quadratic complex associated
to $f$ (see (3.12)). By lemma (3.8), there exists a $\mathscr{W}^{\prime}$-non singular quadratic ( $2 p+2$ )pair $\left(\Sigma_{*} \rightarrow \mathbf{C}_{*}, u\right)$ such that $q$ is the boundary of $u$ and $\Sigma_{i} \rightarrow \mathrm{C}_{i}$ is a simple isomorphism for $i \neq-p-\mathrm{I}$.

The map $\Sigma_{*} \rightarrow \mathrm{C}_{*}$ has the form

where $\mathrm{K} \xrightarrow{d^{\prime}} \Sigma$ is the complex $\Sigma_{*}$.
If $u$ is represented by $\Sigma e_{i} \otimes \psi_{i}, \psi_{0}$ is a homomorphism from $\Sigma$ to $\hat{\Sigma}$ satisfying

$$
\tilde{\psi} \circ d^{\prime}+\hat{\beta} \circ \varphi_{0}=0 \quad \text { with } \tilde{\psi}=\psi_{0}-(-\mathrm{I})^{p} \hat{\psi}_{0}
$$

and the following complex is $\Lambda$-acyclic:

$$
\mathrm{o} \longrightarrow \mathrm{~K} \xrightarrow{d^{\prime}} \Sigma \xrightarrow{\hat{\alpha} \circ \tilde{\psi}} \hat{\mathrm{X}} \longrightarrow 0 .
$$

By the splitting lemma (3.5), there exist two finitely generated free A-modules $\mathbf{C}$ and I and a homomorphism $\gamma: \mathbf{C} \rightarrow \Sigma \oplus \mathbf{I}$ such that $\left(\gamma \oplus d^{\prime}\right) \otimes \Lambda$ is an isomorphism. After adding a kernel to $\Sigma_{*}$, we may suppose that I is zero and $\gamma$ is a homomorphism from C to $\mathrm{\Sigma}$.

Then the morphism $\hat{\alpha} \circ \tilde{\psi} \circ \gamma: \mathbf{C} \rightarrow \hat{\mathrm{X}}$ is a $\Lambda$-isomorphism, and the morphism $\tilde{\psi} \circ \gamma \oplus \hat{\beta}: \mathbf{C} \oplus \hat{\mathrm{B}} \rightarrow \hat{\Sigma}$ is also a $\Lambda$-isomorphism. That implies that the composite map from $\mathbf{C} \oplus \mathrm{K}$ to $\widehat{\mathbf{C}} \oplus \mathbf{B}$

$$
(\hat{\gamma} \circ \hat{\widetilde{\psi}} \oplus \beta) \circ\left(\gamma \oplus d^{\prime}\right)=-(-\mathrm{I})^{p} \hat{\gamma} \circ \tilde{\psi} \circ \gamma \oplus(-\mathrm{I})^{p} \hat{\gamma} \circ \hat{\beta} \circ \varphi_{0} \oplus \beta \circ \gamma \oplus d
$$

is a $\Lambda$-isomorphism.
Let $h$ be the homomorphism from $\mathbf{B} \oplus \hat{\mathbf{B}} \oplus \mathbf{C} \oplus \hat{\mathbf{C}}$ to itself defined by

$$
h=\mathrm{I} \oplus(-\mathrm{I})^{p} \hat{\gamma} \circ \hat{\beta} \oplus(-\mathrm{I})^{p+1} \beta \circ \gamma \oplus(-\mathrm{I})^{p+1} \hat{\gamma} \circ \tilde{\psi} \circ \gamma
$$

It is easy to check that $h$ is an isometry leaving each element of $\mathbf{B} \oplus \hat{\mathbf{C}}$ fixed and that the composite map

$$
\mathbf{K} \oplus \mathbf{C} \xrightarrow{h \circ(t \oplus g)} \mathbf{B} \oplus \hat{\mathbf{B}} \oplus \mathbf{C} \oplus \hat{\mathbf{C}} \longrightarrow \mathbf{B} \oplus \hat{\mathbf{C}}
$$

is a $\Lambda$-isomorphism.

## 4. Geometric surgery

Throughout this section, we will suppose that $A$ is the group ring $\mathbf{Z} \pi$ with an involution induced by a morphism $w: \pi \rightarrow \pm \mathrm{I}$, and that $\mathscr{W}$ is an exact symmetric class in $\mathscr{C}(\mathrm{A})$ containing any acyclic complex with torsion in the image of $\pi \rightarrow \widetilde{\mathrm{K}}_{1}(\mathrm{~A})$.

We denote by $(\Lambda, \alpha)$ the $\mathscr{W}$-localization of $\mathrm{A}(\mathrm{I} .9)$ and by $\mathscr{W}^{\prime}$ the class of $\Lambda$-acyclic
complexes in $\mathscr{C}(\mathrm{A})$. The class $\mathscr{W}^{\prime}$ is exact and symmetric and the $\mathscr{W}^{\prime}$-localization of A is $\left(\Lambda, \widetilde{\mathrm{K}}_{1}(\Lambda)\right)$. The fact that any element in $\widetilde{\mathrm{K}}_{1}(\Lambda)$ is the torsion of a complex $\mathrm{C} \otimes \Lambda$, $\mathrm{C} \in \mathscr{W}^{\prime}$, will be proved in $\S 7$.

Let $f$ be a degree one normal map from the normal bundle of a compact $n$-dimensional (Top, PL or Diff)-manifold V to a (Top, PL or Diff)-bundle $\xi$ over a connected $\mathscr{W}$-Poincaré complex with fundamental group $\pi$, such that the first Stiefel-Whitney class of $\xi$ is $w$. We assume that $f$ induces a $\mathscr{W}$-equivalence on the boundaries.

Suppose that any complex in $\mathscr{W}$ is $\Lambda$-acyclic. Then $f$ induces a $\Lambda$-homology equivalence with torsion in $\alpha$ between the boundaries. Then we can use Wall's technique [io] in order to define $\sigma(f) \in \mathrm{L}_{n}^{\alpha}(\Lambda)$ and $\sigma(f)$ depends only on the normal cobordism class (relative the boundary) of $f$, and vanishes if $f$ is normally cobordant to a $\mathscr{W}$-equivalence.

## (4.1) Proof of theorem (1.10) in the case $\mathscr{W}=\mathscr{W}^{\prime}$

Suppose $n=2 p$ or $2 p+\mathrm{I} \geq 5$ and $\sigma(f)=0$. After performing surgeries, we may suppose that the normal map $f: \mathrm{V} \rightarrow \mathrm{X}$ is $p$-connected.

Denote by $\mathbf{C}_{*}$ the complex $\Sigma^{-1} \mathrm{C}_{*}(\mathrm{X}, \mathrm{V} ; \mathbf{Z} \pi)$. If $g$ is a homotopy inverse of the cap product $\mathrm{C}^{*}(\mathrm{~V} ; \mathbf{Z} \pi) \rightarrow \mathrm{G}_{*}(\mathrm{~V}, \partial \mathrm{~V} ; \mathbf{Z} \pi)$, the composite map

$$
\mathrm{C}_{*} \rightarrow \mathrm{C}_{*}(\mathrm{~V} ; \mathbf{Z} \pi) \rightarrow \mathrm{C}_{*}(\mathrm{~V}, \partial \mathrm{~V} ; \mathbf{Z} \pi) \xrightarrow{g} \mathrm{C}^{*}(\mathrm{~V} ; \mathbf{Z} \pi) \rightarrow \widehat{\mathrm{C}}_{*}
$$

is a $\mathscr{W}^{\prime}$-equivalence.
a) The even dimensional case

If $n=2 p$, we have a complex in $\mathscr{W}^{\prime}$

$$
\ldots \rightarrow \mathrm{C}_{p+1} \rightarrow \mathrm{C}_{p} \rightarrow \widehat{\mathrm{C}}_{p} \rightarrow \widehat{\mathrm{C}}_{p+1} \rightarrow \ldots
$$

and by the splitting lemma (3.5), there exist two complexes $L$ and $L^{\prime}$ concentrated in dimension $p$ and a $\mathscr{W}^{\prime}$-equivalence $\mathrm{L} \rightarrow \mathrm{C}_{*} \oplus \mathrm{~L}^{\prime}$.

After performing trivial surgeries, we may suppose that $L^{\prime}$ is zero. Then the intersection and self-intersection forms on $\mathrm{H}_{p+1}(\mathrm{X}, \mathrm{V} ; \mathbf{Z} \pi)$ induce forms $\lambda$ and $\mu$ on $\mathrm{L}_{p}$ and $\left(\mathrm{L}_{p}, \lambda, \mu\right)$ is a $\mathscr{W}^{\prime}$-special (-I) ${ }^{p}$-form. Clearly, $\omega\left(\mathrm{L}_{p}, \lambda, \mu\right)$ is sent to $\sigma(f)$ by the canonical map: $\varepsilon: \Gamma_{n}\left(\mathbf{Z} \pi, \mathscr{W}^{\prime}\right) \rightarrow \mathrm{L}_{n}^{h}(\Lambda)$.

But $\varepsilon$ is an isomorphism. This will be proved in $\S 8$.
Then $\omega\left(\mathrm{L}_{p}, \lambda, \mu\right)$ is zero and by proposition (3.14), the direct sum of ( $\mathrm{L}_{p}, \lambda, \mu$ ) and $\mathrm{a}(-\mathrm{I})^{p}$-kernel has a $\mathscr{W}^{\prime}$-subkernel. We can realize the direct sum by trivial surgeries. So we may as well suppose that $\left(\mathrm{L}_{p}, \lambda, \mu\right)$ has a $\mathscr{W}^{\prime}$-subkernel $\mathrm{K} \rightarrow \mathrm{L}_{p}$. Now it suffices to perform surgeries along a basis of K , via the map $\mathrm{K} \rightarrow \mathrm{L}_{p} \rightarrow \mathrm{C}_{p} \rightarrow \mathrm{H}_{p+1}(\mathrm{X}, \mathrm{V} ; \mathbf{Z} \pi)$, to get a $\mathscr{W}^{\prime}$-equivalence.
b) The odd dimensional case

If $n=2 p+1$, we have a complex in $\mathscr{W}^{\prime}$

$$
\ldots \rightarrow \mathrm{C}_{p+2} \rightarrow \mathrm{C}_{p+1} \rightarrow \mathrm{C}_{p} \oplus \hat{\mathrm{C}}_{p} \rightarrow \hat{\mathrm{C}}_{p+1} \rightarrow \hat{\mathrm{C}}_{p+2} \rightarrow \ldots
$$

and by the splitting lemma (3.5), there exist two complexes $L$ and $L^{\prime}$ concentrated in dimension $p+\mathrm{I}$ and a $\mathscr{W}^{\prime}$-equivalence

$$
\mathrm{L} \rightarrow\left(\ldots \rightarrow \mathrm{C}_{p+2} \rightarrow \mathrm{C}_{p+1} \rightarrow \mathrm{o} \rightarrow \ldots\right) \oplus \mathrm{L}^{\prime}
$$

So we get a $\mathscr{W}^{\prime}$-equivalence $\left(\ldots \rightarrow 0 \rightarrow \mathrm{~L}_{p+1} \rightarrow \mathrm{C}_{p} \oplus \mathrm{~L}_{p+1}^{\prime} \rightarrow \mathrm{o} \rightarrow \ldots\right.$ ) $\rightarrow \mathrm{C}$.
Denote by $\mathrm{K} \xrightarrow{d} \mathrm{~B}$ the map $\mathrm{L}_{p+1} \rightarrow \mathrm{C}_{p} \oplus \mathrm{~L}_{p+1}^{\prime}$, and consider the composite map $\mathrm{B} \rightarrow \mathrm{C}_{p} \rightarrow \pi_{p+1}(\mathrm{X}, \mathrm{V})$. The basis of B induces maps from $\mathrm{S}^{p}$ to V homotopic to zero in X . These maps are covered by fibered maps and we get immersions $\alpha_{i}: \mathrm{S}^{p} \rightarrow \mathrm{~V}$, which we can suppose to be disjoint embeddings. Let $U$ be a regular neighborhood of the images of these embeddings, connectified with I -handles. The group $\mathrm{H}_{p+1}(\mathrm{pt}, \partial \mathrm{U} ; \mathbf{Z} \pi)$ endowed with intersection and self-intersection forms is the standard $(-1)^{p}$ - kernel $\mathbf{B} \oplus \hat{\mathbf{B}}$.

The morphisms $\mathrm{K} \rightarrow \mathrm{B}$ and $\mathrm{K} \rightarrow \mathrm{C}_{p+1}$ induce a morphism from K to the relative homology group
and we get, upon composing with the boundary, a morphism $h$ from K to

$$
\mathrm{H}_{p+1}(\partial \mathrm{U} \rightarrow \mathrm{pt} ; \mathbf{Z} \pi)=\mathrm{H}_{p+1}(\mathrm{pt}, \partial \mathrm{U} ; \mathbf{Z} \pi)=\mathbf{B} \oplus \hat{\mathbf{B}} .
$$

It is not difficult to see that the image under $h$ of the basis of K can be represented by spheres immersed in $\partial \mathrm{U}$ with zero intersections and self-intersections. To prove that $h$ is a $\mathscr{W}^{\prime}$-subkernel, it suffices to show that the complex $\ldots \rightarrow \mathrm{o} \rightarrow \mathrm{K} \rightarrow \mathrm{B} \oplus \widehat{\mathrm{B}} \rightarrow \widehat{\mathrm{K}} \rightarrow \mathrm{o} \rightarrow \ldots$ lies in $\mathscr{W}^{\prime}$; and this follows from the $\mathscr{W}^{\prime}$-equivalences

$$
(\ldots \rightarrow \mathrm{o} \rightarrow \mathrm{~K} \rightarrow \mathrm{~B} \rightarrow \ldots) \rightarrow \mathrm{C}_{*} \rightarrow \widehat{\mathrm{C}}_{*} \rightarrow(\ldots \rightarrow \mathrm{o} \rightarrow \hat{\mathrm{~B}} \rightarrow \hat{\mathrm{~K}} \rightarrow \mathrm{o} \rightarrow \ldots) .
$$

Then we get a $\mathscr{W}^{\prime}$-subkernel $h$ and an invariant $\omega(h) \in \Gamma_{n}\left(\mathbf{Z} \pi, \mathscr{W}^{\prime}\right)$. By construction, $\omega(h)$ is sent to $\sigma(f)$ by the isomorphism $\varepsilon: \Gamma_{n}\left(\mathbf{Z}_{\pi}, \mathscr{W}^{\prime}\right) \rightarrow \mathrm{L}_{n}^{h}(\Lambda)$. Hence $\omega(h)$ is zero. By proposition (3.15), there exist a standard (-1) ${ }^{p}$-kernel $\mathbf{C} \oplus \hat{\mathrm{C}}$ endowed with its standard subkernel $g: \mathbf{C} \rightarrow \mathbf{C} \oplus \hat{\mathbf{C}}$ and an automorphism $\varphi$ on $\mathbf{B} \oplus \hat{\mathbf{B}} \oplus \mathbf{C} \oplus \widehat{\mathbf{C}}$ leaving each element of $\mathrm{B} \oplus \widehat{\mathrm{C}}$ fixed, such that the composite map

$$
\mathbf{K} \oplus \mathbf{C} \xrightarrow{\varphi(h \oplus g)} \mathbf{B} \oplus \hat{\mathbf{B}} \oplus \mathbf{C} \oplus \widehat{\mathbf{C}} \longrightarrow \mathbf{B} \oplus \hat{\mathbf{C}}
$$

is a $\Lambda$-isomorphism.
If we add trivial disjoint embeddings $\beta_{j}$, from $\mathrm{S}^{p}$ to V , corresponding to the basis of C , the new $\mathscr{W}^{\prime}$-subkernel is $h \oplus g$. If we perform surgeries along the spheres $\alpha_{i}$, the $\mathscr{W}^{\prime}$-subkernel $h \oplus g$ is replaced by $\mathrm{T} \circ(h \oplus g)$, where T exchanges the factors B and $\hat{\mathbf{B}}$. The new embedded spheres are the duals $\bar{\alpha}_{i}$ of $\alpha_{i}$ and $\beta_{j}$.

Now we can choose a regular homotopy depending on $\varphi$ (see [io]) to get new disjoint embeddings $\alpha_{i}^{\prime}$ and $\beta_{j}^{\prime}$ and the $\mathscr{W}^{\prime}$-subkernel $\mathrm{T} \circ \varphi \circ(h \oplus g)$.

If we perform surgeries along the spheres $\alpha_{i}^{\prime}$ and $\beta_{j}^{\prime}$, we get the $\mathscr{W}^{\prime}$-subkernel $\mathrm{T}^{\prime} \circ \varphi \circ(h \oplus g)$ where $\mathrm{T}^{\prime}$ exchanges the factors C and $\widehat{\mathrm{C}}$.

So we obtain a new normal map $f^{\prime}: \mathrm{V}^{\prime} \rightarrow \mathrm{X}$ normally cobordant to $f$ and a $\mathscr{W}^{\prime}$-equivalence

$$
(\ldots \rightarrow \mathrm{o} \rightarrow \mathrm{~K} \oplus \mathbf{C} \rightarrow \mathrm{~B} \oplus \widehat{\mathrm{C}} \rightarrow \mathrm{o} \rightarrow \ldots) \rightarrow \Sigma^{-1} \mathrm{C}_{*}\left(\mathrm{X}, \mathrm{~V}^{\prime} ; \mathbf{Z} \pi\right)
$$

Therefore $f^{\prime}$ is a $\mathscr{W}^{\prime}$-equivalence.
(4.2) Proof of theorem (1.11) in the case $\mathscr{W}=\mathscr{W}^{\prime}$
a) The even dimensional case

Suppose $n=2 p \geq 6$ and let $\sigma \in \mathrm{L}_{n}^{h}(\Lambda)$. Since the morphism

$$
\varepsilon: \Gamma_{n}\left(\mathbf{Z} \pi, \mathscr{W}^{\prime}\right) \rightarrow \mathrm{L}_{n}^{h}(\Lambda)
$$

is an isomorphism, $\sigma$ is represented by a $\mathscr{W}^{\prime}$-special (-I) ${ }^{p}$-form ( $H, \lambda, \mu$ ) (3.13). Then we construct a normal map $f: \mathrm{W} \rightarrow \mathrm{M} \times \mathrm{I}$ exactly as in ([10], p. 53). This normal map is an isomorphism over $\mathrm{M} \times 0 \cup \partial \mathrm{M} \times \mathrm{I}$ and a $\mathscr{W}^{\prime}$-equivalence over $\mathrm{M} \times \mathrm{I}$ because $\lambda$ is $\mathscr{W}^{\prime}$-non singular. By construction, $\sigma$ is the surgery invariant of $f$.
b) The odd dimensional case

Suppose $n=2 p+\mathrm{I} \geq 7$ and let $\sigma \in \mathrm{L}_{n}^{h}(\Lambda)$. We can represent $\sigma$ by a trivial $(-\mathrm{I})^{p}$-kernel $\mathrm{B} \oplus \hat{\mathbf{B}}$ endowed with a $\mathscr{W}^{\prime}$-subkernel $g: \mathbf{K} \rightarrow \mathbf{B} \oplus \hat{\mathbf{B}} \quad$ ((3.14)). After adding $p$-handles to $\mathrm{M} \times \mathrm{I}$ corresponding to the basis of B , we get a normal map $f_{0}: \mathrm{W}_{0} \rightarrow \mathrm{M} \times\left[0, \frac{\mathrm{I}}{2}\right]$ which restricts to an isomorphism over $\mathrm{M} \times \mathrm{o} \cup \partial \mathrm{M} \times\left[0, \frac{\mathrm{I}}{2}\right]$. The inverse image $M^{\prime}$ of $M \times \frac{1}{2}$ is the connected sum of $M$ and copies of $S^{p} \times S^{p}$ and the group $\pi_{p+1}\left(\mathbf{M} \times \frac{1}{2}, M^{\prime}\right)$ is the kernel $\mathbf{B} \oplus \hat{B}$. Then we can perform surgeries along the image under $g$ of the basis of $K$ and we get a normal map

$$
f_{1}: \mathrm{W}_{1} \rightarrow \mathrm{M} \times\left[\frac{\mathrm{I}}{2}, \mathrm{I}\right]
$$

These two normal maps induce a normal map $f: \mathrm{W} \rightarrow \mathrm{M} \times \mathrm{I}$. It is easy to see that $f$ restricts to an isomorphism over $\mathrm{M} \times o \cup \partial \mathrm{M} \times \mathrm{I}$ and a $\mathscr{W}^{\prime}$-equivalence over $\mathbf{M} \times \mathrm{I} . \quad$ Moreover $\sigma$ is the surgery obstruction $\sigma(f)$.

Actually this proof is almost identical with [ro], p. 66.
Lemma (4.3). - Let $\tau \in \widetilde{\mathrm{K}}_{\mathbf{1}}(\Lambda)$. Then there exist two matrices $u$ and $v$ with entries in A such that $u \otimes \Lambda$ and $v \otimes \Lambda$ are invertible and $\tau=\tau(u \otimes \Lambda)-\tau(v \otimes \Lambda)$.

This lemma will be proved in $\S 7$.
Lemma (4.4). - Let M be a connected compact (Top, PL or Diff)-manifold, $\operatorname{dim} \mathrm{M} \geq 5$. Let $\varphi$ be an epimorphism from $\pi_{1} \mathrm{M}$ to $\pi$ and $\tau$ be an element of $\widetilde{\mathrm{K}}_{1}(\Lambda)$. Then, there exists a normal
map $f: \mathrm{V} \rightarrow \mathrm{M} \times \mathrm{I}$ restricting to an isomorphism over $\mathrm{M} \times o \cup \partial \mathrm{M} \times \mathrm{I}$ and such that $f$ is a $\Lambda$-homology equivalence with torsion $\tau$.

Proof. - By lemma (4-3), there exist two matrices

$$
u: \mathbf{Z} \pi^{p} \rightarrow \mathbf{Z} \pi^{q} \quad \text { and } \quad v: \mathbf{Z} \pi^{r} \rightarrow \mathbf{Z} \pi^{s}
$$

such that $u \otimes \Lambda$ and $v \otimes \Lambda$ are invertible and

$$
\tau=\tau(u \otimes \Lambda)-\tau(v \otimes \Lambda) .
$$

After adding $q$-handles to $\mathrm{M} \times \mathrm{I}$, we get a normal map $f_{1}: \mathrm{V}_{1} \rightarrow \mathrm{M} \times \mathrm{I}$ which is trivial on the handles. Now we add $p$ 2-handles on $\mathrm{V}_{1}$ along $u$ and we get a normal map $f_{2}: \mathrm{V}_{\mathbf{2}} \rightarrow \mathrm{M} \times \mathrm{I}$ restricting to an isomorphism over $\mathrm{M} \times o \cup \partial \mathrm{M} \times \mathrm{I}$ and such that: $\tau\left(f_{2}\right)=\tau(u \otimes \Lambda) \in \widetilde{\mathrm{K}}_{1}(\Lambda)$.

Let $\mathrm{M}^{\prime}$ be the manifold $f_{2}^{-1}(\mathrm{M} \times \mathrm{I})$. After adding $s$ trivial 2 -handles and $r 3$-handles along $v$, we construct a normal map $f_{3}^{\prime}: \mathrm{V}_{3}^{\prime} \rightarrow \mathrm{M}^{\prime} \times \mathrm{I}$ which restricts to an isomorphism over $\mathrm{M}^{\prime} \times \mathrm{o} \cup \partial \mathrm{M}^{\prime} \times \mathrm{I}$, and $f_{3}^{\prime}$ is a $\Lambda$-homology equivalence with torsion $-\tau(v \otimes \Lambda)$.

Then after gluing $f_{2}$ and $f_{3}^{\prime}$ together, we get a normal map $f: \mathrm{V} \rightarrow \mathrm{M} \times \mathrm{I}$ which has the desired property.
(4.5) Proof of theorem (1.10) in the general case

Consider the Ranicki-Rothenberg exact sequence

$$
\mathrm{L}_{n+1}^{h}(\Lambda) \xrightarrow{\partial} \mathrm{H}^{n}\left(\mathbf{Z} / 2, \widetilde{\mathrm{~K}}_{1}(\Lambda) / \alpha\right) \rightarrow \mathrm{L}_{n}^{\alpha}(\Lambda) \rightarrow \mathrm{L}_{n}^{h}(\Lambda) .
$$

Suppose that $\sigma(f)$ vanishes in $\mathrm{L}_{n}^{\alpha}(\Lambda)$. Then the surgery invariant of $f$ is zero in $\mathrm{L}_{n}^{h}(\Lambda)$ and $f$ is normally cobordant (relative the boundary) to a normal map $f_{1}: \mathrm{V}_{1} \rightarrow \mathrm{X}$ which is a $\mathscr{W}^{\prime}$-equivalence. Moreover $f_{1}$ is $\left[\frac{n}{2}\right]$-connected.

Let $\tau \in \widetilde{\mathbf{K}}_{1}(\Lambda)$ be the torsion of $f_{1}$. Since $\sigma(f)$ is zero, there exists an element $u \in \mathrm{~L}_{n+1}^{h}(\Lambda)$ such that $\partial u$ is represented by $\tau$. But $f_{1}$ is 2 -connected and $\pi_{1} \mathrm{~V}_{1}=\pi$. Then, by theorem (I.II) (proved in the case $\mathscr{W}=\mathscr{W}^{\prime}, \mathrm{M}=\mathrm{V}_{1}$ ), there exists a normal map $g_{1}: \mathrm{W}_{1} \rightarrow \mathrm{~V}_{1} \times \mathrm{I}$ restricting to an isomorphism over $\mathrm{V}_{1} \times o \cup \partial \mathrm{~V}_{1} \times \mathrm{I}$ and such that $\sigma(g)=u$. This normal map induces a normal cobordism (relative the boundary) from $f_{1}$ to a normal map $f_{2}: \mathrm{V}_{2} \rightarrow \mathrm{X}$ which is a $\mathscr{W}^{\prime}$-equivalence. Moreover the torsion of $f_{2}$ is zero in $\mathrm{H}^{n}\left(\mathbf{Z} / 2, \widetilde{\mathrm{~K}}_{1}(\Lambda) / \alpha\right)$.

Then, there exists $\tau^{\prime} \in \widetilde{\mathrm{K}}_{1}(\Lambda)$ such that: $\tau\left(f_{2}\right) \equiv \tau^{\prime}+(-\mathrm{I})^{n} \bar{\tau}^{\prime}(\bmod \alpha)$.
By lemma (4.4), there exists a normal map $g_{2}: \mathrm{W}_{2} \rightarrow \mathrm{~V}_{2} \times \mathrm{I}$ restricting to an isomorphism over $\mathrm{V}_{2} \times o \cup \partial \mathrm{~V}_{2} \times \mathrm{I}$ such that $g_{2}$ is a $\mathscr{W}^{\prime}$-equivalence with torsion $-\tau^{\prime}$. This normal map induces a normal cobordism from $f_{2}$ to $f_{3}: \mathrm{V}_{3} \rightarrow \mathrm{X}$ and $f_{3}$ is a $\mathscr{W}^{\prime}$-equivalence with torsion in $\alpha \subset \widetilde{\mathrm{K}}_{1}(\Lambda)$. Thus, theorem (I.10) is a trivial consequence of the following lemma (proved in § 7):

Lemma (4.6). - Any finite A-complex which is $\Lambda$-acyclic with torsion in $\alpha$ lies in $\mathscr{W}$.
(4.7) Proof of theorem (1.11) in the general case

Consider again the Ranicki-Rothenberg exact sequence

$$
\mathrm{H}^{n}\left(\mathbf{Z} / 2, \widetilde{\mathrm{~K}}_{1}(\Lambda) / \alpha\right) \rightarrow \mathrm{L}_{n}^{\alpha}(\Lambda) \rightarrow \mathrm{L}_{n}^{h}(\Lambda) \rightarrow \mathrm{H}^{n-1}\left(\mathbf{Z} / 2, \widetilde{\mathrm{~K}}_{1}(\Lambda) / \alpha\right) .
$$

Let $\sigma$ be an element of $\mathrm{L}_{n}^{\alpha}(\Lambda)$ and $\sigma^{\prime}$ be the image of $\sigma$ in $\mathrm{L}_{n}^{h}(\Lambda)$. By theorem (I.ir) (proved in the case $\mathscr{W}=\mathscr{W}^{\prime}$ ) there exists a normal map $f_{1}: \mathrm{W}_{1} \rightarrow \mathrm{M} \times \mathrm{I}$ restricting to an isomorphism over $\mathrm{M} \times o \cup \partial \mathrm{M} \times \mathrm{I}$ and such that the surgery obstruction of $f_{1}$ is $\sigma^{\prime}$ in $\mathrm{L}_{n}^{h}(\Lambda)$. Let $\mathrm{V}_{1}$ be the inverse image of $\mathrm{M} \times \mathrm{I}$. Since $\sigma^{\prime}$ is sent to zero in $\mathrm{H}^{n-1}\left(\mathbf{Z} / 2, \widetilde{\mathrm{~K}}_{1}(\Lambda) / \alpha\right)$ the torsion of $f_{1}: \mathrm{V}_{1} \rightarrow \mathrm{M}$ is congruent to $\tau-(-1)^{n} \bar{\tau}(\bmod \alpha)$ for some $\tau \in \widetilde{\mathrm{K}}_{1}(\Lambda)$.

Then, by lemma (4.4), we can glue together $f_{1}$ and a normal map $f_{1}^{\prime}: \mathrm{W}_{1}^{\prime} \rightarrow \mathrm{M} \times \mathrm{I}$ in order to construct a new normal map $f_{2}: \mathrm{W}_{2} \rightarrow \mathrm{M} \times \mathrm{I}$ such that
(i) $f_{1}$ and $f_{2}$ have the same invariant in $\mathrm{L}_{n}^{h}(\Lambda)$;
(ii) $f_{2}$ restricts over $\mathrm{M} \times \mathrm{I}$ to a $\mathscr{W}^{\prime}$-equivalence with torsion in $\alpha$.

By construction, $\sigma\left(f_{2}\right)-\sigma$ is the image of an element of $\mathrm{H}^{n}\left(\mathbf{Z} / 2, \widetilde{\mathrm{~K}}_{\mathbf{1}}(\Lambda) / \alpha\right)$ represented by $\tau^{\prime} \in \widetilde{\mathrm{K}}_{1}(\Lambda)$. By lemma (4.4), there exists a normal map
$f_{2}^{\prime}: \mathrm{W}_{2}^{\prime} \rightarrow f_{2}^{-1}(\mathrm{M} \times \mathrm{I}) \times \mathrm{I}$
restricting to an isomorphism over $f_{2}^{-1}(\mathrm{M} \times \mathrm{I}) \times o \cup \partial f_{2}^{-1}(\mathrm{M} \times \mathrm{I}) \times \mathrm{I}$ and such that $f_{2}^{\prime}$ is a $\mathscr{W}^{\prime}$-equivalence with torsion $-\tau^{\prime}$. Then, after gluing $f_{2}$ and $f_{2}^{\prime}$ together, we get a normal map $f: \mathrm{W} \rightarrow \mathrm{M} \times \mathrm{I}$ with surgery obstruction $\sigma$.

## 5. Localization in the category of graded differential modules

Consider now the general case: A is a ring and $\mathscr{W}$ is an exact class in $\mathscr{C}(\mathrm{A})$. The $\mathscr{W}$-localization of A is $(\Lambda, \alpha)$.

Definition (5.1). - A complex $\mathrm{C} \in \mathscr{W}$ will be called $\mathscr{W}$-splittable if there exist, for any $n$, an $n$-dimensional complex $\mathrm{C}^{\prime} \in \mathscr{W}$ and an ( $n-\mathrm{I}$ )-connected morphism from $\mathrm{C}^{\prime}$ to C .

The class of $\mathscr{W}$-splittable complexes of $\mathscr{W}$ will be called $\mathscr{W}^{s}$.
Lemma (5.2). - The class $\mathscr{W}^{s}$ is exact.
Proof. - The class $\mathscr{W}^{s}$ is clearly stable under simple homotopy equivalence and under any suspension.

Now let $\mathrm{o} \rightarrow \mathrm{C} \rightarrow \mathrm{C}^{\prime} \rightarrow \mathrm{C}^{\prime \prime} \rightarrow \mathrm{o}$ be a $s$-exact sequence of finite A-complexes. Suppose that $\mathbf{C}$ and $\mathbf{C}^{\prime}$ are $\mathscr{W}$-splittable.

Let $n$ be an integer. There exists a diagram

such that $\overline{\mathrm{C}}$ (respectively $\overline{\mathrm{C}}^{\prime}$ ) is an ( $n-1$ )-dimensional (respectively $n$-dimensional) complex in $\mathscr{W}$ and the morphism $\overline{\mathrm{C}} \rightarrow \mathbf{C}$ (respectively $\overline{\mathrm{C}}^{\prime} \rightarrow \mathbf{C}^{\prime}$ ) is ( $n-2$ )-connected (respectively $(n-1)$-connected). The obstructions to factoring the morphism $\overline{\mathrm{C}} \rightarrow \mathrm{C}^{\prime}$ through $\overline{\mathrm{C}}^{\prime}$ are in the groups $\mathrm{H}^{p}\left(\overline{\mathrm{C}}, \mathrm{H}_{p}\left(\mathbf{C}^{\prime}, \overline{\mathrm{C}}^{\prime}\right)\right)$ which are all trivial. So we get a morphism $\overline{\mathbf{C}} \rightarrow \overline{\mathrm{C}}^{\prime}$. It is easy to see that the mapping cone $\overline{\mathrm{C}}^{\prime \prime}$ of $\overline{\mathrm{C}} \rightarrow \overline{\mathrm{C}}^{\prime}$ is an $n$-dimensional complex in $\mathscr{W}$ and the induced morphism from $\overline{\mathrm{C}}^{\prime \prime}$ to $\mathrm{C}^{\prime \prime}$ is ( $n-1$ )connected.

Then $\mathrm{C}^{\prime \prime}$ is $\mathscr{W}$-splittable and, since $\mathscr{W}^{s}$ is stable under simple homotopy equivalence and suspension, it is easy to prove that $\mathscr{W}^{s}$ is exact.

Lemma (5.3). $-\mathscr{W}^{s s}=\mathscr{W}^{s}$.
Proof. - The proof is by induction on the length of the complex. Clearly any complex in $\mathscr{W}^{s}$ of length two is $\mathscr{W}^{s}$-splittable. Suppose any complex in $\mathscr{W}^{s}$ of length $<p$ is $\mathscr{W}^{s}$-splittable, and let $\mathrm{C} \in \mathscr{W}^{s}$ be a $\mathscr{W}$-splittable complex of length $p$. The complex C is $n$-dimensional and $(n-p)$-connected. Since C is $\mathscr{W}$-splittable, there exist an $(n-p+2)$-dimensional complex $\quad \mathrm{C}^{\prime} \in \mathscr{W}$ and an $(n-p+1)$-connected morphism $\mathrm{C}^{\prime} \rightarrow \mathrm{C}$.

The length of $\mathrm{C}^{\prime}$ is 2 and $\mathrm{C}^{\prime}$ lies in $\mathscr{W}^{\text {ss }}$. Then the mapping cone of $\mathrm{C}^{\prime} \rightarrow \mathrm{C}$ is a complex in $\mathscr{W}^{s}$ of length $p-\mathrm{I}$. By induction the mapping cone of $\mathrm{C}^{\prime} \rightarrow \mathrm{C}$ lies in $\mathscr{W}^{s s}$ and $\mathrm{C} \in \mathscr{W}^{s s}$.

We will work out a theory of localization in the category of graded differential modules. Unfortunately, the category $\mathscr{C}(\mathrm{A})$ is too small to do that and we must consider the category $\overline{\mathscr{C}}(\mathrm{A})$ of graded differential free A-modules bounded from below.

Notations (5.4). - Denote by $\mathscr{W}_{0}$ the exact class of finite A-complexes C such that $\mathrm{C} \oplus \Sigma \mathrm{C}$ lies in $\mathscr{W}$ and by $\mathscr{W}_{0}^{s}$ the class $\left(\mathscr{W}_{0}\right)^{s}$. We use $\overline{\mathscr{W}}$ to denote the class of complexes $\mathrm{C} \in \overline{\mathscr{C}}(\mathrm{A})$ such that any morphism from a finite A-complex to C factorizes through a complex in $\mathscr{W}_{0}^{s}$.

A morphism $f$ in $\overline{\mathscr{C}}(\mathrm{A})$ is a $\overline{\mathscr{W}}$-equivalence if the mapping cone of $f$ lies in $\overline{\mathscr{W}}$.
Definition (5.5). - A complex $\mathrm{C} \in \overline{\mathscr{C}}(\mathrm{A})$ will be called local if any morphism from a complex $\mathrm{C}^{\prime} \in \bar{W}$ to C is null homotopic.

A morphism $f: \mathrm{C} \rightarrow \mathrm{C}^{\prime}$ is a localization of C if $f$ is a $\overline{\mathscr{W}}$-equivalence and $\mathrm{C}^{\prime}$ is local. Clearly, if G has a localization, this localization is unique up to homotopy.

Proposition (5.6). - Any complex in $\overline{\mathscr{C}}(\mathrm{A})$ has a localization.
Proof. - Let $\mathrm{C} \in \overline{\mathscr{C}}(\mathrm{A})$. Suppose C is $(n-\mathrm{I})$-connected. Let $\mathscr{A}$ be the set of morphisms $\mathrm{K} \rightarrow \mathrm{C}$ such that K is a $(n-2)$-connected complex in $\mathscr{W}_{0}^{s}$. Let $\Phi(\mathrm{C})$ be the mapping cone of the morphism $\underset{\mathscr{\infty}}{ } \mathrm{K}^{2} \rightarrow \mathrm{C}$.

Clearly $\Phi(\mathrm{C})$ is $(n-\mathrm{I})$-connected and we can carry on this process:

$$
\mathrm{C} \rightarrow \Phi(\mathrm{C}) \rightarrow \Phi^{2}(\mathrm{C}) \rightarrow \Phi^{3}(\mathrm{C}) \rightarrow \ldots
$$

Denote by $\mathrm{E}(\mathrm{C})$ the limit of this system.
The complex $\Phi^{p+1}(\mathbf{C}) / \Phi^{p}(\mathbf{C})$ is a direct sum of complexes in $\mathscr{W}_{0}^{s}$. Then, by induction, it is easy to show that $\Phi^{p}(\mathrm{C}) / \mathrm{C}$ lies in $\overline{\mathscr{W}}$. But, by construction, $\mathrm{E}(\mathrm{C})$ is $(n-1)$-connected and $\mathrm{E}(\mathrm{C}) \in \overline{\mathscr{C}}(\mathrm{A})$. Moreover $\mathrm{E}(\mathrm{C}) / \mathrm{C}$ lies in $\overline{\mathscr{W}}$ and $\mathrm{G} \rightarrow \mathrm{E}(\mathrm{C})$ is a $\overline{\mathscr{W}}$-equivalence.

Now, let $\mathscr{C}$ be the class of complexes $\mathrm{C}^{\prime} \in \overline{\mathscr{C}}(\mathrm{A})$ such that any morphism from $\mathrm{C}^{\prime}$ to $\mathrm{E}(\mathrm{C})$ is null homotopic. The class $\mathscr{C}$ is stable under homotopy equivalence and extension. The last problem is to prove that $\mathscr{C}$ contains $\overline{\mathscr{W}}$.

Let $\mathrm{K} \in \mathscr{W}_{0}^{s}$. Since any complexe in $\mathscr{W}_{0}^{s}$ is $\mathscr{W}_{0}^{s}$-splittable ( $(5 \cdot 3)$ ), there exists a homotopy $s$-exact sequence $\mathrm{o} \rightarrow \mathrm{K}^{\prime} \rightarrow \mathrm{K} \rightarrow \mathrm{K}^{\prime \prime} \rightarrow \mathrm{o}$ such that $\mathrm{K}^{\prime}$ is a $n-\mathrm{I}$-dimensional complex in $\mathscr{W}_{0}^{s}$ and $\mathrm{K}^{\prime \prime}$ an $(n-2)$-connected complex in $\mathscr{W}_{0}^{s}$. Clearly $\mathrm{K}^{\prime} \in \mathscr{C}$. Let $f$ be a morphism from $\mathrm{K}^{\prime \prime}$ to $\mathrm{E}(\mathbf{C})$. Since $\mathrm{K}^{\prime \prime}$ is finitely generated, the image of $f$ is contained in some $\Phi^{p}(\mathbf{C})$ and $f$ is homotopic to zero in $\Phi^{p+1}(\mathbf{C})$. Hence $\mathbf{K}^{\prime \prime} \in \mathscr{C}$ and $\mathrm{K} \in \mathscr{C}$ too. Then $\mathscr{C}$ contains the class $\mathscr{W}_{0}^{s}$.

If $\mathrm{K} \in \overline{\mathscr{C}}(\mathrm{A})$, denote by $\mathscr{H}^{i}(\mathrm{~K})$ the group [ $\left.\Sigma^{-i} \mathrm{~K}, \mathrm{E}(\mathrm{C})\right]$ of homotopy classes of morphisms from $\Sigma^{-i} \mathrm{~K}$ to $\mathrm{E}(\mathrm{C})$. The group $\mathscr{H}^{i}(\mathrm{~K})$ vanishes for any $\mathrm{K} \in \mathscr{W}_{0}^{s}$ and any $i \in \mathbf{Z}$, and we must prove that $\mathscr{H}^{\circ}(\mathrm{K})$ is zero for any $\mathrm{K} \in \overline{\mathscr{W}}$.

If $\mathrm{K} \in \overline{\mathscr{W}}, \mathrm{K}$ has the homotopy type of the limit of a directed system $\mathrm{K}_{i}, \mathrm{~K}_{i} \in \mathscr{W}_{0}^{s}$, and we have a spectral sequence with the following $\mathrm{E}_{2}$ term:

$$
\mathrm{E}_{2}^{p q}=\lim _{\leftarrow}^{p} \mathscr{H}^{q}\left(\mathrm{~K}_{i}\right) .
$$

The $\mathrm{E}_{2}$ term is trivial and the spectral sequence converges to $\mathscr{H}^{*}(\mathrm{~K})$. Then $\mathscr{H}^{0}(\mathrm{~K})$ vanishes and $\mathrm{C} \rightarrow \mathrm{E}(\mathrm{C})$ is a localization of C .

The localization plays an important role in view of the following propositions:
Proposition (5.7). - Let C and $\mathrm{C}^{\prime}$ be two complexes in $\mathscr{C}(\mathrm{A})$, with $\operatorname{dim} \mathrm{C}=n$. Let $\mathbf{C}^{\prime} \xrightarrow{\varepsilon} \mathrm{E}\left(\mathrm{C}^{\prime}\right)$ be a localization of $\mathrm{C}^{\prime}$. Then, for any morphism $f: \mathrm{C} \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime}\right)$, there exist an $n$-dimensional complex $\overline{\mathrm{C}} \in \mathscr{C}(\mathrm{A})$ and a homotopy commutative diagram

such that $\overline{\mathrm{C}} \rightarrow \mathrm{C}$ is a $\mathscr{W}_{0}^{s}$-equivalence.

Proposition (5.8). - Let C and $\mathrm{C}^{\prime}$ be two complexes in $\mathscr{C}(\mathrm{A})$ with $\operatorname{dim} \mathrm{C}=n$. Let $\mathrm{C}^{\prime} \xrightarrow{\boldsymbol{\varepsilon}} \mathrm{E}\left(\mathrm{C}^{\prime}\right)$ be a localization of $\mathrm{C}^{\prime} . \quad$ Let $f: \mathrm{C} \rightarrow \mathrm{C}^{\prime}$ be a map such that $\varepsilon \circ f$ is null homotopic. Then, there exists a $\mathscr{W}_{0}^{s}$-equivalence $\overline{\mathbf{C}} \rightarrow \mathbf{C}$ such that $\overline{\mathbf{C}} \in \mathscr{C}(\mathrm{A})$ is $n$-dimensional and the composite map $\overline{\mathbf{G}} \rightarrow \mathbf{G} \xrightarrow{\mathbf{t}} \mathbf{C}^{\prime}$ is null homotopic.

Proof of (5.7). - Suppose $\varepsilon$ is monic with free cokernel. We have an exact sequence

$$
\mathrm{o} \rightarrow \mathrm{C}^{\prime} \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime}\right) \rightarrow \mathrm{K}^{\prime} \rightarrow \mathrm{o}, \quad \mathrm{~K}^{\prime} \in \overline{\mathscr{W}} .
$$

Let us construct the homotopy commutative diagram

in the following way: Since $C$ is finitely generated, the map $C \rightarrow K^{\prime}$ factorizes through a complex $\mathrm{L} \in \mathscr{W}_{0}^{s}$ and by (5.3), there exist an ( $n+1$ )-dimensional complex $\mathrm{K} \in \mathscr{W}_{0 \mathrm{~s}}$ and an $n$-connected map $\mathrm{K} \rightarrow \mathrm{L}$. Then there is no obstruction to factorize the map $\mathrm{C} \rightarrow \mathrm{L}$ through K .

Let $\overline{\mathrm{C}}$ be the homotopy kernel of $\mathbf{G} \rightarrow \mathrm{K}$. It is easy to check that $\overline{\mathrm{C}}$ is $n$-dimensional and that the map $\overline{\mathrm{C}} \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime}\right)$ factorizes through $\mathrm{C}^{\prime}$.

Proof of (5.8). - Suppose $\varepsilon$ is epic with kernel $\mathrm{K}^{\prime} \in \overline{\mathscr{W}}$. Since the composite $\operatorname{map} \mathrm{C} \xrightarrow{f} \mathrm{C}^{\prime} \xrightarrow{\varepsilon} \mathrm{E}\left(\mathrm{C}^{\prime}\right)$ is null homotopic, $f$ is homotopic to a map $f^{\prime}: \mathrm{C} \rightarrow \mathrm{K}^{\prime}$. Then $f^{\prime}$ factorizes through a complex $\mathrm{L} \in \mathscr{W}_{0}^{s}$. By ( $5 \cdot 3$ ), there exist an ( $n+1$ )-dimensional complex $\mathrm{K} \in \mathscr{W}_{0}^{s}$ and an $n$-connected map $\mathrm{K} \rightarrow \mathrm{L}$. As before the map $\mathrm{G} \rightarrow \mathrm{L}$ retracts in K and the homotopy kernel of $\mathrm{G} \rightarrow \mathrm{K}$ has the desired properties.

## 6. The ring $\Lambda$

In this section, we will compute the homology groups of the localization of a complex $\mathrm{C} \in \overline{\mathscr{C}}(\mathrm{A})$ in terms of the ring $\Lambda$ defined in (i.8).

Let M be a (right) A-module. This module will be said local if any $q \times p$ matrix in $\Sigma$ induces an isomorphism $\operatorname{Hom}\left(\mathrm{A}^{q}, \mathrm{M}\right) \rightarrow \operatorname{Hom}\left(\mathrm{A}^{p}, \mathrm{M}\right)$.

Lemma (6.1). - A module M is local if and only if $\mathrm{H}^{n}(\mathrm{C}, \mathrm{M})$ vanishes for any $n \in \mathbf{Z}$ and any $\mathrm{C} \in \overline{\mathscr{W}}$.

Proof. - Suppose that $\mathrm{H}^{n}(\mathbf{C}, \mathrm{M})$ vanishes for any $n \in \mathbf{Z}$ and any $\mathbf{C} \in \overline{\mathscr{W}}$. If $u$ is a matrix in $\Sigma$, denote by C the I -dimensional complex

$$
\ldots \rightarrow 0 \rightarrow \mathrm{~A}^{p} \xrightarrow{u} \mathrm{~A}^{q} \rightarrow 0 \rightarrow \ldots
$$

Then $\mathrm{G} \oplus \Sigma \mathrm{G}$ lies in $\mathscr{W}$ (see (1.7)) and C is a complex of $\mathscr{W}_{0}^{s} \subset \overline{\mathscr{W}}$. Hence $\mathrm{H}^{*}(\mathrm{C}, \mathrm{M})$ vanishes and M is local.

Conversely, suppose $M$ is local and denote by $\mathscr{C}$ the class of complexes $C \in \overline{\mathscr{C}}(\mathrm{~A})$ such that $\mathrm{H}^{*}(\mathrm{C}, \mathrm{M})=\mathrm{o}$.

If C is a complex of length two in $\mathscr{W}_{0}^{s}, \mathrm{C}$ lies in $\mathscr{C}$ by definition.
If C is a complex in $\mathscr{W}_{0}^{s}$ of length $p>2$, there exists a homotopy $s$-exact sequence

$$
\mathrm{o} \rightarrow \mathrm{C}^{\prime} \rightarrow \mathrm{C} \rightarrow \mathrm{C}^{\prime \prime} \rightarrow \mathrm{o}
$$

such that $\mathrm{C}^{\prime}$ and $\mathrm{C}^{\prime \prime}$ are complexes in $\mathscr{W}_{0}^{s}$ of length $<p$.
By induction, C is in $\mathscr{C}$ and $\mathscr{C}$ contains the class $\mathscr{W}_{0}^{s}$.
If $\mathrm{C} \in \overline{\mathscr{W}}, \mathrm{C}$ is the limit of a directed system $\mathrm{C}_{i} \in \mathscr{W}_{0}^{s}$ and we have a spectral sequence with $\mathrm{E}_{2}$ term $\mathrm{E}_{2}^{p q}=\lim ^{p} \mathrm{H}^{q}\left(\mathrm{C}_{i}, \mathrm{M}\right)$. The $\mathrm{E}_{2}$ term is zero and the spectral sequence converges to $\mathrm{H}^{*}(\mathrm{C}, \mathrm{M})$. Hence $\mathrm{H}^{*}(\mathrm{C}, \mathrm{M})$ vanishes and the lemma is proved.

Corollary (6.2). - $A$ complex $\mathrm{C} \in \overline{\mathcal{C}}(\mathrm{A})$ is local if and only if $\mathrm{H}_{n}(\mathrm{C})$ is local for any $n \in \mathbf{Z}$.

Proof. - If K is a complex, denote by $\mathscr{H}^{i}(\mathrm{~K})$ the group of homotopy classes of maps $\Sigma^{-i} \mathrm{~K} \rightarrow \mathrm{C}$. We have a spectral sequence with $\mathrm{E}_{\mathbf{2}}$ term

$$
\mathrm{E}_{2}^{p q}=\mathrm{H}^{p}\left(\mathrm{~K}, \mathrm{H}_{-q}(\mathrm{C})\right)
$$

and this spectral sequence usually converges to $\mathscr{H}^{*}(\mathrm{~K})$.
Suppose C is local and let $\mathrm{K} \in \mathscr{W}_{0}^{s}$ be a complex of length 2 defined by a matrix $u \in \Sigma$. Then the above spectral sequence collapses to exact sequences

$$
\mathrm{o} \rightarrow \mathrm{H}^{n}\left(\mathrm{~K}, \mathrm{H}_{-i}(\mathrm{C})\right) \rightarrow \mathscr{H}^{n+i}(\mathrm{~K}) \rightarrow \mathrm{H}^{n-1}\left(\mathrm{~K}, \mathrm{H}_{-i-1}(\mathrm{C})\right) \rightarrow \mathrm{o} \quad(n=\operatorname{dim} \mathrm{K})
$$

Then all the groups $\mathrm{H}^{*}\left(\mathrm{~K}, \mathrm{H}_{i}(\mathrm{C})\right)$ vanish and $\mathrm{H}_{i}(\mathrm{C})$ is local for any $i \in \mathbf{Z}$.
Conversely suppose $H_{*}(\mathrm{C})$ is local. Then for any $\mathrm{K} \in \overline{\mathscr{W}}$, the $\mathrm{E}_{2}$ term of the above spectral sequence vanishes and the spectral sequence converges to $\mathscr{H}^{*}(\mathrm{~K})$. Hence this last group vanishes and C is local.

Lemma (6.3). - Localization respects exact sequences.
Proof. - Let $\mathrm{o} \rightarrow \mathbf{C} \rightarrow \mathbf{C}^{\prime} \rightarrow \mathbf{C}^{\prime \prime} \rightarrow \mathbf{o}$ be a short exact sequence in $\overline{\mathscr{C}}(\mathrm{A})$. Take localizations $\mathbf{C} \rightarrow \mathrm{E}(\mathbf{C})$ and $\mathrm{C}^{\prime} \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime}\right)$ of C and $\mathrm{C}^{\prime}$. We get a commutative diagram

Let $\mathrm{E}\left(\mathrm{C}^{\prime \prime}\right)$ be the mapping cone of $\mathrm{E}(\mathrm{C}) \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime}\right)$. We have a homotopy commutative diagram

Clearly $\mathrm{E}\left(\mathrm{C}^{\prime \prime}\right)$ is local and the map $\mathrm{C}^{\prime \prime} \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime \prime}\right)$ is a $\overline{\mathscr{W}}$-equivalence. Then $\mathrm{C}^{\prime \prime} \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime \prime}\right)$ is a localization of $\mathrm{C}^{\prime \prime}$ and the result follows.

Lemma (6.4). - Localization respects direct sums.
Proof. - Let $\mathrm{C}_{i} \in \overline{\mathscr{C}}(\mathrm{~A})$ be a class of complexes. Suppose that $\mathrm{C}_{i}$ is $(n-1)$ connected for any $i$, and take localizations $\mathrm{G}_{\boldsymbol{i}} \rightarrow \mathrm{E}\left(\mathrm{G}_{\boldsymbol{i}}\right)$.

Clearly the mapping cone of $\bigoplus_{i} \mathrm{G}_{i} \rightarrow \bigoplus_{i} \mathrm{E}\left(\mathrm{C}_{i}\right)$ lies in $\overline{\mathscr{W}}$ and, by (6.2), the sum $\bigoplus_{i} \mathrm{E}\left(\mathrm{C}_{i}\right)$ is local. Then the map $\bigoplus_{i} \mathrm{C}_{\boldsymbol{i}} \rightarrow \underset{i}{\oplus} \mathrm{E}\left(\mathrm{C}_{i}\right)$ is a localization of $\bigoplus_{i} \mathrm{G}_{\boldsymbol{i}}$.

Now if C is a complex in $\overline{\mathscr{C}}(\mathrm{A})$, denote by $\Phi_{n}(\mathrm{C})$ the group $\mathrm{H}_{n}(\mathrm{E}(\mathrm{C}))$ where $\mathrm{C} \rightarrow \mathrm{E}(\mathrm{C})$ is a localization of C .

If M is a (right) A-module, we will also denote by $\Phi_{n}(\mathrm{M})$ the group $\Phi_{n}(\mathrm{C})$ where C is a free resolution of M . The $\Phi_{n}$ 's are functors and we have a natural transformation $\eta: M \rightarrow \Phi_{0}(M)$.

Clearly, if M is local, a resolution of M is local ((6.2)). So $\eta$ is bijective and $\Phi_{i}(\mathrm{M})$ vanishes for $i \neq 0$.

Lemma (6.5). - Let M be an A-module. Then, there is a natural homomorphism

$$
\varepsilon^{\prime}: \mathrm{M} \otimes_{\mathbf{Z}} \Phi_{0}(\mathrm{~A}) \rightarrow \Phi_{0}(\mathrm{M}),
$$

such that the following diagram commutes:

Proof. - Let $m \in \mathrm{M}$. Denote by $\varphi: \mathrm{A} \rightarrow \mathrm{M}$ the homomorphism $a \mapsto m a$. By setting $\varepsilon^{\prime}(m, x)=\Phi_{0}(\varphi)(x)$, for any $x \in \Phi_{0}(\mathrm{~A})$, we get a map $\varepsilon^{\prime}: \mathrm{M} \times \Phi_{0}(\mathrm{~A}) \rightarrow \Phi_{0}(\mathrm{M})$. Clearly, $\varepsilon^{\prime}(m, x)$ is $\mathbf{Z}$-linear on $x$ and, since $\Phi_{0}$ respects direct sums, it is easy to see that $\varepsilon^{\prime}(m, x)$ is $\mathbf{Z}$-linear on $m$.

Lemma (6.6). - The module $\Phi_{0}(\mathrm{~A})$ is a ring and $\varepsilon^{\prime}$ induces a homomorphism

$$
\varepsilon: \mathrm{M} \otimes_{\mathrm{A}} \Phi_{0}(\mathrm{~A}) \rightarrow \Phi_{0}(\mathrm{M}) .
$$

Proof. - Let $m \in \mathrm{M}$ and $x, y \in \Phi(\mathrm{~A})$. Denote by $\varphi: \mathrm{A} \rightarrow \mathrm{M}$ the map $a \mapsto m a$ and by $\psi: \mathrm{A} \rightarrow \Phi_{0}(\mathrm{~A})$ the map $a \rightarrow x a$.

We have a commutative diagram

and the following formulas:

$$
\begin{aligned}
& \Phi_{0}^{2}(\varphi) \circ \Phi_{0}(\psi)(y)=\Phi_{0}^{2}(\varphi)\left(\varepsilon^{\prime}(x, y)\right)=\eta \varepsilon^{\prime}\left(m, \eta^{-1} \varepsilon^{\prime}(x, y)\right) \\
& \Phi_{0}\left[\Phi_{0}(\varphi) \circ \psi\right](y)=\varepsilon^{\prime}\left(\varepsilon^{\prime}(m, x), y\right) \\
& \eta \varepsilon^{\prime}\left(m, \eta^{-1} \varepsilon^{\prime}(x, y)\right)=\varepsilon^{\prime}\left(\varepsilon^{\prime}(m, x), y\right) .
\end{aligned}
$$

Then the map $\eta^{-1} \varepsilon^{\prime}$ from $\Phi_{0}(\mathrm{~A}) \otimes_{\mathbf{Z}} \Phi_{0}(\mathrm{~A})$ to $\Phi_{0}(\mathrm{~A})$ induces a ring structure on $\Phi_{0}(\mathrm{~A})$ and $\eta$ is a ring homomorphism from A to $\Phi_{0}(\mathrm{~A})$. Moreover $\varepsilon^{\prime}$ induces a homomorphism $\varepsilon: M \otimes_{A} \Phi_{0}(A) \rightarrow \Phi_{0}(M)$.

Lemma (6.7). - The ring homomorphism $\mathrm{A} \rightarrow \Phi_{\mathbf{0}}(\mathrm{A})$ is isomorphic to the homomorphism $\mathrm{A} \rightarrow \Lambda$.

Proof. - Let A $\rightarrow$ B be a ring homomorphism. The A-module B is local if and only if any $q \times p$ matrix $u \in \Sigma$ induces an isomorphism $u^{*}: \operatorname{Hom}\left(\mathrm{A}^{q}, \mathrm{~B}\right) \rightarrow \operatorname{Hom}\left(\mathrm{A}^{p}, \mathrm{~B}\right)$. But the matrix of $u^{*}$ is the transpose of $u \otimes \mathrm{~B}$. Then, B is local if and only if, for any $u \in \Sigma, u \otimes B$ is invertible.

Hence, for any matrix $u \in \Sigma, u \otimes \Phi_{0}(\mathrm{~A})$ is invertible and we will prove that $\Phi_{0}(\mathrm{~A})$ is universal with respect to this property.

Let $\mathrm{A} \rightarrow \mathrm{B}$ be a ring homomorphism such that $u \otimes \mathrm{~B}$ is invertible for any $u \in \Sigma$. Let us choose free resolutions $A_{*}$ and $B_{*}$ of $A$ and $B$ and a localization $A_{*} \rightarrow E\left(A_{*}\right)$ of $A_{*}$. Since $B$ is local, there exists an extension $E\left(A_{*}\right) \rightarrow B_{*}$ unique up to homotopy. Then there exists a unique extension $\Phi_{0}(\mathrm{~A}) \rightarrow \mathrm{B}$ of $\mathrm{A} \rightarrow \mathrm{B}$.

Consider the following diagram:

All the morphisms of this diagram are ring homomorphisms and $\mathrm{B} \xrightarrow[\rightarrow]{\sim} \Phi_{0}(\mathrm{~B})$ is an isomorphism. Then the extension $\Phi_{0}(\mathrm{~A}) \rightarrow \mathrm{B}$ is a ring homomorphism. So $\mathrm{A} \rightarrow \Phi_{0}(\mathrm{~A})$ satisfies the universal property of $\Lambda$ and $\mathrm{A} \rightarrow \Phi_{0}(\mathrm{~A})$ is isomorphic to $\mathrm{A} \rightarrow \Lambda$.

Lemma (6.8). - For any module M , the morphism $\varepsilon: \mathrm{M} \otimes \Lambda \rightarrow \Phi_{0}(\mathrm{M})$ is an isomorphism.
Proof. - By lemma (6.4), the functor $\Phi_{0}$ respects direct sums and $\varepsilon$ is an isomorphism if M is free. Moreover, by lemma (6.5), $\Phi_{0}$ is right exact and $\varepsilon$ is an isomorphism for any M .

Corollary (6.9). - If M is local, the canonical map $\mathrm{M} \rightarrow \mathrm{M} \otimes \Lambda$ is an isomorphism.
Lemma (6.10). - If M is local, $\operatorname{Tor}_{\mathbf{1}}(\mathrm{M}, \Lambda)$ is trivial.
Proof. - Choose a free module L and an exact sequence

$$
\mathrm{o} \rightarrow \mathrm{~N} \rightarrow \mathrm{~L} \rightarrow \mathrm{M} \rightarrow \mathrm{o} .
$$

By lemma (6.4), we have an exact sequence

$$
\Phi_{1}(\mathrm{M}) \rightarrow \Phi_{0}(\mathrm{~N}) \rightarrow \Phi_{0}(\mathrm{~L}) \rightarrow \Phi_{0}(\mathrm{M}) \rightarrow 0 .
$$

If M is local, $\Phi_{1}(\mathrm{M})$ is zero and $\Phi_{0}(\mathrm{~N}) \rightarrow \Phi_{0}(\mathrm{~L})$ is monic. But this map is isomorphic to the map $\mathrm{N} \otimes \Lambda \rightarrow \mathrm{L} \otimes \Lambda$ and its kernel is $\operatorname{Tor}_{1}(\mathrm{M}, \Lambda)$.

Corollary (6.11). - Let $\mathrm{C} \in \overline{\mathscr{C}}(\mathrm{A})$ be an $(n-\mathrm{I})$-connected local complex. Then the canonical map $\mathrm{H}_{i}(\mathbf{C}) \rightarrow \mathrm{H}_{i}(\mathbf{C} \otimes \Lambda)$ is an isomorphism for $i \leq n$ and an epimorphism for $i=n+\mathrm{r}$.

Proof. - We have a spectral sequence with $\mathrm{E}^{2}$ term $\mathrm{E}_{p q}^{2}=\operatorname{Tor}_{p}\left(\mathrm{H}_{q}(\mathrm{C}), \Lambda\right)$ which converges to $\mathrm{H}_{*}(\mathrm{C} \otimes \Lambda)$. Since C is local, $\mathrm{H}_{*}(\mathrm{C})$ is local and, by (6.9) and (6.ro), we have

$$
\begin{aligned}
& \mathrm{E}_{0 q}^{2}=\operatorname{Tor}_{0}\left(\mathrm{H}_{q}(\mathrm{C}), \Lambda\right)=\mathrm{H}_{q}(\mathrm{C}), \\
& \mathrm{E}_{1 q}^{2}=\operatorname{Tor}_{1}\left(\mathrm{H}_{q}(\mathbf{C}), \Lambda\right)=\mathrm{o}
\end{aligned}
$$

The result follows.

Theorem (6.12). - Let C and $\mathrm{C}^{\prime}$ be two finite A -complexes and suppose that $\mathrm{C}^{\prime} \otimes \Lambda$ is $(n-1)$-connected. Then we have the following properties:
(i) If $\mathrm{H}^{i}(\mathrm{C}, \Lambda)$ vanishes for $i>n+\mathrm{I}$ and $f$ is a morphism from $\mathrm{C} \otimes \Lambda$ to $\mathrm{C}^{\prime} \otimes \Lambda$, there exist a $\mathscr{W}_{0}^{s}$-equivalence $\varepsilon: \overline{\mathrm{C}} \rightarrow \mathrm{C}$ with $\operatorname{dim} \overline{\mathrm{C}}=\operatorname{dim} \mathrm{C}$ and a morphism $g: \overline{\mathrm{C}} \rightarrow \mathrm{C}^{\prime}$ such that $g \otimes \Lambda$ is homotopic to $f \circ(\varepsilon \otimes \Lambda)$.
(ii) If $\mathrm{H}^{i}(\mathrm{C}, \Lambda)$ vanishes for $i>n$ and $f$ is a morphism from C to $\mathrm{C}^{\prime}$ such that $f \otimes \Lambda$ is null homotopic, there exists a $\mathscr{W}_{0}^{s}$-equivalence $\varepsilon: \overline{\mathrm{C}} \rightarrow \mathrm{C}$, with $\operatorname{dim} \overline{\mathrm{C}}=\operatorname{dim} \mathrm{C}$ such that $f \circ \varepsilon$ is null homotopic.

Proof. - Let $\mathrm{C}^{\prime} \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime}\right)$ be a localization of $\mathrm{C}^{\prime}$ and consider the following diagram:

If $f$ is a morphism from $\mathbf{C} \otimes \Lambda$ to $\mathbf{C}^{\prime} \otimes \Lambda, f$ is defined by an A-homomorphism $f^{\prime}: \mathrm{C} \rightarrow \mathrm{C}^{\prime} \otimes \Lambda$.

The obstructions to lift the composite map $f^{\prime \prime}: \mathrm{C} \rightarrow \mathbf{C}^{\prime} \otimes \Lambda \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime}\right) \otimes \Lambda$ through $\mathrm{E}\left(\mathbf{C}^{\prime}\right)$ lie in the groups $\mathrm{H}^{p}\left(\mathrm{C}, \mathrm{H}_{p}\left(\mathrm{E}\left(\mathbf{C}^{\prime}\right) \otimes \Lambda, \mathrm{E}\left(\mathrm{C}^{\prime}\right)\right)\right)$. Let $\mathrm{H}_{p}$ be the module $\mathrm{H}_{p}\left(\mathrm{E}\left(\mathrm{C}^{\prime}\right) \otimes \Lambda, \mathrm{E}\left(\mathrm{C}^{\prime}\right)\right)$. Since $\mathrm{E}\left(\mathrm{C}^{\prime}\right)$ is local, $\mathrm{H}_{p}$ is a $\Lambda$-module and is trivial for $p \leq n+\mathrm{I}$, by (6.1I). But $\mathrm{H}^{i}(\mathrm{C}, \Lambda)$ vanishes for $i>n+\mathrm{I}$ and the localization $\mathrm{E}(\widehat{\mathrm{C}})$ of $\widehat{\mathrm{C}}$ is $(-n-2)$-connected. Then we have, for $p>n+\mathrm{r}$,

$$
\mathrm{H}^{p}\left(\mathrm{C}, \mathrm{H}_{p}\right)=\mathrm{H}_{-p}\left(\widehat{\mathrm{C}}, \mathrm{H}_{p}\right)=\mathrm{H}_{-p}\left(\mathrm{E}(\widehat{\mathrm{C}}), \mathrm{H}_{p}\right)=0 .
$$

Then $f^{\prime \prime}$ lifts through $\mathrm{E}\left(\mathbf{C}^{\prime}\right)$ and, by (5.7), there exist a complex $\overline{\mathrm{C}} \in \mathscr{C}(\mathrm{A})$ with $\operatorname{dim} \overline{\mathrm{C}}=\operatorname{dim} \mathrm{C}$, a $\mathscr{W}_{0}^{s}$-equivalence $\varepsilon: \overline{\mathrm{C}} \rightarrow \mathbf{C}$ and a morphism $g: \overline{\mathrm{C}} \rightarrow \mathrm{C}^{\prime}$ such that the following diagram is homotopy commutative:

On the other hand, any complex in $\mathscr{W}_{0}^{s}$ of length two is $\Lambda$-acyclic and, by induction, any complex in $\mathscr{W}_{0}^{s}$ is $\Lambda$-acyclic. This implies that any complex in $\overline{\mathscr{W}}$ is $\Lambda$-acyclic and $\mathrm{C}^{\prime} \otimes \Lambda \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime}\right) \otimes \Lambda$ is a homotopy equivalence.

Then the following diagram commutes up to homotopy:

and part (i) of the theorem is proved.
Suppose now $f$ is a morphism from $\mathbf{C}$ to $\mathbf{C}^{\prime}$ with $\operatorname{dim} \mathbf{C}=n$. If $f \otimes \Lambda$ is null homotopic, the composite map $\mathbf{G} \rightarrow \mathbf{C}^{\prime} \rightarrow \mathrm{E}\left(\mathbf{C}^{\prime}\right) \otimes \Lambda$ is null homotopic and, by obstruction, the map $\mathrm{C} \rightarrow \mathrm{E}\left(\mathrm{C}^{\prime}\right)$ is null homotopic. Then we may apply (5.8) and the theorem is proved.

## 7. The structure of $\mathscr{W}$

Lemma (7.1). - The class $\mathscr{W}_{0}^{s}$ is the class $\mathscr{W}^{\prime}$ of $\Lambda$-acyclic complexes in $\mathscr{C}(\mathrm{A})$.
Proof. - If C is a complex in $\mathscr{W}_{0}$ of length two, it is $\Lambda$-acyclic by definition of $\Lambda$. Then, by induction, any complex in $\mathscr{W}_{0}^{s}$ is $\Lambda$-acyclic.

Conversely, let $\mathrm{C} \in \mathscr{C}(\mathrm{A})$ be a $\Lambda$-acyclic complex and $\mathrm{C} \rightarrow \mathrm{E}(\mathrm{C})$ be a localization of $C$. Since $C$ is $\Lambda$-acyclic, $E(C)$ is $\Lambda$-acyclic too. Suppose $E(C)$ is not acyclic and let $\mathrm{H}_{n}$ be the first non trivial homology group of $\mathrm{E}(\mathrm{C})$. The module $\mathrm{H}_{n}$ is local and

$$
\mathrm{H}_{n} \simeq \mathrm{H}_{n} \otimes \Lambda \simeq \mathrm{H}_{n}(\mathrm{E}(\mathrm{C}) \otimes \Lambda)=\mathrm{o} .
$$

Hence $\mathrm{E}(\mathrm{C})$ is acyclic and $\mathrm{C} \in \overline{\mathscr{W}}$. Since $\mathbf{C}$ is finite, the identity $\mathrm{C} \rightarrow \mathrm{C}$ factorizes through a complex $\mathrm{K} \in \mathscr{W}_{0}^{s}$ and we get a split exact sequence

$$
\mathrm{o} \rightarrow \mathrm{C}^{\prime} \rightarrow \mathrm{K} \rightarrow \mathrm{C} \rightarrow \mathrm{o} .
$$

This implies that $\mathbf{C} \oplus \mathbf{C}^{\prime}$ has the simple homotopy type of $K$ and $\mathbf{C} \oplus \mathbf{C}^{\prime}$ lies in $\mathscr{W}_{0}^{s}$.
On the other hand, $\Sigma \mathrm{K}$ has the simple homotopy type of the mapping cone of the zero map $\mathrm{C}^{\prime} \rightarrow \Sigma \mathrm{C}$ and $\mathrm{C}^{\prime} \rightarrow \Sigma \mathrm{C}$ is a $\mathscr{W}_{0}^{s}$-equivalence. Then $\mathrm{C} \oplus \Sigma \mathrm{C}$ lies in $\mathscr{W}_{0}^{s}$.

Now we will prove that G is in $\mathscr{W}_{0}^{s}$ by induction on the length of G .
If the length of $\mathbf{G}$ is two, $\mathbf{C} \oplus \Sigma \mathrm{C}$ is contained in $\mathscr{W}_{0}$ and $\mathrm{G} \oplus \Sigma G \oplus \Sigma G \oplus \Sigma^{2} \mathrm{C}$ lies in $\mathscr{W}$. But $\Sigma\left(\mathbf{C} \oplus \Sigma \mathrm{G} \oplus \Sigma \mathrm{G} \oplus \Sigma^{2} \mathrm{C}\right)$ is the mapping cone of the zero map $\Sigma \mathbf{G} \oplus \Sigma \mathbf{G} \oplus \Sigma^{2} \mathbf{G} \rightarrow \Sigma \mathbf{C}$ which is a $\mathscr{W}$-equivalence. Then $\mathbf{G} \oplus \Sigma \mathbf{C}$ lies in $\mathscr{W}$ and $\mathbf{C}$ lies in $\mathscr{W}_{0}$. Since the length of G is two, C lies in $\mathscr{W}_{0}^{s}$.

If the length of C is $p>2, \mathrm{C}$ is $n$-dimensional and ( $n-p$ )-connected. Since $\mathbf{C} \oplus \Sigma \mathrm{G}$ is $\mathscr{W}_{0}^{s}$-splittable, there exist an ( $n-p+2$ )-dimensional complex $\mathrm{K} \in \mathscr{W}_{0}^{s}$ and an ( $n-p+\mathrm{I}$ )-connected morphism $f \oplus g$ from K to $\mathrm{C} \oplus \Sigma \mathrm{C}$.

The morphism $f \oplus \mathrm{o}$ is clearly $(n-p+\mathrm{r})$-connected. Let M be the mapping cone of $f$. The complex $\mathrm{M} \oplus \Sigma \mathrm{M}$ is the mapping cone of $f \oplus \Sigma f$ and lies in $\mathscr{W}_{0}^{s}$. But the length of M is $p-\mathrm{I}$. By induction, M lies in $\mathscr{W}_{0}^{s}$ and C lies in $\mathscr{W}_{0}^{s}$ too.
(7.2) Proof of the splitting lemma (3.5)

Let C be a complex in $\mathscr{W}^{\prime}$ and let $n$ be an integer. Since $\mathscr{W}^{\prime}=\mathscr{W}_{0}^{s}, \mathrm{C}$ is $\mathscr{W}^{\prime}$-splittable and there exist an $n$-dimensional complex $\mathbf{C}^{\prime} \in \mathscr{W}^{\prime}$ and an $(n-1)$-connected morphism $\mathrm{C}^{\prime} \rightarrow \mathrm{C}$.

Up to simple homotopy type, we may suppose that the map $\mathrm{C}_{i}^{\prime} \rightarrow \mathrm{C}_{i}$ is bijective for $i<n-\mathrm{I}$ and is epic with free kernel $\mathrm{L}_{n}^{\prime}$ for $i=n-\mathrm{I}$. Then we have the following complex in $\mathscr{W}^{\prime}$ :

$$
\ldots \rightarrow \mathrm{C}_{n+2} \rightarrow \mathrm{C}_{n+1} \oplus \mathrm{C}_{n}^{\prime} \rightarrow \mathrm{C}_{n} \oplus \mathrm{~L}_{n}^{\prime} \rightarrow \mathrm{o} \rightarrow \ldots
$$

Now by setting

$$
\begin{aligned}
& \mathrm{L}=\left(\ldots \rightarrow \mathrm{o} \rightarrow \mathrm{C}_{n}^{\prime} \rightarrow \mathrm{o} \rightarrow \ldots\right) \\
& \mathrm{L}^{\prime}=\left(\ldots \rightarrow \mathrm{o} \rightarrow \mathrm{~L}_{n}^{\prime} \rightarrow \mathrm{o} \rightarrow \ldots\right)
\end{aligned}
$$

we get a $\mathscr{W}^{\prime}$-equivalence

$$
\mathrm{L} \rightarrow \mathrm{~L}^{\prime} \oplus\left(\ldots \rightarrow \mathrm{C}_{n+1} \rightarrow \mathrm{C}_{n} \rightarrow \mathrm{o} \rightarrow \ldots\right)
$$

Lemma (7.3). - For any complex $\mathbf{C} \in \mathscr{W}^{\prime}$, the complex $\mathbf{C} \oplus \Sigma \mathrm{C}$ lies in $\mathscr{W}$.
Proof. - If C is $\Lambda$-acyclic, C lies in $\mathscr{W}_{0}^{\mathrm{s}} \subset \mathscr{W}_{0}$ and then $\mathrm{C} \oplus \Sigma \mathrm{C} \in \mathscr{W}$.
(7.4) We use $\mathrm{K}(\mathscr{W})$ to denote the class of complexes $\mathrm{C} \in \mathscr{W}^{\prime}$ fulfilling the following relation:

$$
\mathbf{C} \sim \mathrm{C}^{\prime} \Leftrightarrow \mathbf{G} \oplus \Sigma \mathrm{C}^{\prime} \in \mathscr{W}
$$

By (7-3), this relation is an equivalence relation and $\mathrm{K}(\mathscr{W})$ is a well defined set. Moreover the direct sum of complexes induces an abelian group structure on $K(\mathscr{W})$.

If G is a $\Lambda$-acyclic complex in $\mathscr{C}(\mathrm{A})$, the class of C in $\mathrm{K}(\mathscr{W})$ will be denoted by $\theta(\mathrm{C})$.

Lemma (7.5). - Let $\mathrm{o} \rightarrow \mathrm{C} \rightarrow \mathrm{C}^{\prime} \rightarrow \mathrm{C}^{\prime \prime} \rightarrow \mathrm{o}$ be an s-exact sequence of $\Lambda$-acyclic complexes in $\mathscr{C}(\mathrm{A})$. Then $\theta\left(\mathbf{C}^{\prime}\right)=\theta(\mathbf{C})+\theta\left(\mathbf{C}^{\prime \prime}\right)$.

Proof. - We have an $s$-exact sequence

$$
\mathbf{o} \rightarrow \mathbf{C} \oplus \Sigma \mathbf{C} \rightarrow \mathbf{C}^{\prime} \oplus \Sigma \mathbf{C} \oplus \Sigma \mathbf{C}^{\prime \prime} \rightarrow \mathbf{C}^{\prime \prime} \otimes \Sigma \mathbf{C}^{\prime \prime} \rightarrow \mathrm{o}
$$

and, by lemma (7.3), $\mathbf{C}^{\prime} \oplus \Sigma \mathbf{S} \oplus \Sigma \mathrm{C}^{\prime \prime}$ is in $\mathscr{W}$. That proves the lemma.
Now if $f$ is a $\Lambda$-homology equivalence between two finite A-complexes, we will define $\theta(f)$ as the class of the mapping cone of $f$ in $\mathrm{K}(\mathscr{W})$.

Lemma (7.6). - Let $f: \mathbf{C} \rightarrow \mathbf{C}$ and $g: \mathbf{C}^{\prime} \rightarrow \mathbf{C}^{\prime \prime}$ be two $\Lambda$-homology equivalences between finite A-complexes. Then $\theta(g \circ f)=\theta(f)+\theta(g)$.

Proof. - We have a short $s$-exact sequence between the mapping cones of $f, g$, $g \circ f \oplus \mathbf{I}_{\mathbf{C}^{\prime}}$. Then the result follows from (7.5).
(7.7) Let $f: \Lambda^{p} \rightarrow \Lambda^{q}$ be an isomorphism. Denote also by A the o-dimensional complex $\ldots \rightarrow 0 \rightarrow \mathrm{~A} \rightarrow 0 \rightarrow \ldots$ Then $f$ is a morphism from $\mathrm{A}^{p} \otimes \Lambda$ to $\mathrm{A}^{q} \otimes \Lambda$, and, by (6.12), there exist a $\mathscr{W}^{\prime}$-equivalence $\varepsilon: \overline{\mathrm{C}} \rightarrow \mathrm{A}^{p}$ and a map $g: \overline{\mathrm{C}} \rightarrow \mathrm{A}^{q}$ such that $f \circ(\varepsilon \otimes \Lambda)$ is homotopic to $g \otimes \Lambda$.

Since $f$ is an isomorphism, $g$ is a $\mathscr{W}^{\prime}$-equivalence.
Then we define $\theta(f)$ as $\theta(g)-\theta(\varepsilon)$. By (6.12), it is easy to show that $\theta(f)$ does not depend on the choices.

Lemma (7.8). - Let $f: \Lambda^{p} \rightarrow \Lambda^{q}$ and $g: \Lambda^{q} \rightarrow \Lambda^{r}$ be two isomorphisms. Then we have

$$
\theta(g \circ f)=\theta(f)+\theta(g) .
$$

Proof. - By theorem (6.12), there exists a homotopy commutative diagram in $\mathscr{C}$ (A)

such that the morphisms are $\Lambda$-homology equivalences and $h \otimes \Lambda$ and $h^{\prime} \otimes \Lambda$ are homotopic to $f \circ(\varepsilon \otimes \Lambda)$ and $g \circ\left(\varepsilon^{\prime} \otimes \Lambda\right)$. Then we have

$$
\theta(g \circ f)=\theta\left(h^{\prime} \circ \bar{h}\right)-\theta(\varepsilon \circ \bar{\varepsilon})=\theta\left(h^{\prime}\right)+\theta(\bar{h})-\theta(\varepsilon)-\theta(\bar{\varepsilon})
$$

whence

$$
\theta(g \circ f)=\theta\left(h^{\prime}\right)-\theta(\varepsilon)+\theta(h)-\theta\left(\varepsilon^{\prime}\right)=\theta(f)+\theta(g) .
$$

Theorem (7.9). - The torsion homomorphism $\varepsilon: \mathrm{K}(\mathscr{W}) \rightarrow \widetilde{\mathrm{K}}_{\mathbf{1}}(\Lambda) / \alpha$ is an isomorphism.
Proof. - If $x \in \widetilde{\mathrm{~K}}_{1}(\Lambda) / \alpha$ is represented by an isomorphism $f: \Lambda^{p} \rightarrow \Lambda^{q}$, we have $\varepsilon(\theta(f)) \equiv \tau(f) \bmod \alpha \Rightarrow x=\varepsilon(\theta(f))$
and $\varepsilon$ is surjective.
Now let $\theta$ be an element of Ker $\varepsilon$, represented by a complex $\mathbf{C} \in \mathscr{W}^{\prime}$. Since $\varepsilon(\theta)$ vanishes, $\tau(\mathbf{C} \otimes \Lambda)$ is in $\alpha$ and $\tau(\mathbf{C} \otimes \Lambda)$ is the torsion of a complex $\mathbf{C}^{\prime} \otimes \Lambda$ where $\mathrm{C}^{\prime}$ is a $\Lambda$-acyclic complex in $\mathscr{W}$. Then $\theta$ is represented by $\mathrm{C} \oplus \Sigma \mathrm{G}^{\prime}$ and the torsion of $\left(\mathbf{C} \oplus \Sigma \mathbf{C}^{\prime}\right) \otimes \Lambda$ vanishes. Since $\mathscr{W}^{\prime}$ is splittable, we can "split" $\mathbf{C} \oplus \Sigma \mathbf{C}^{\prime}$ into complexes $\mathrm{C}_{i} \in \mathscr{W}^{\prime}$ of length 2. And we have

$$
\theta=\Sigma \theta\left(\mathrm{C}_{i}\right) \quad \text { and } \quad \Sigma_{\tau}\left(\mathrm{C}_{i} \otimes \Lambda\right)=0 .
$$

On the other hand, the suspension $\Sigma^{2}$ does not change the invariants $\theta$ and $\tau$. So we may as well suppose that the complexes $\mathrm{C}_{i}$ are 1 or 2 -dimensional.

Then there exist two I-dimensional complexes in $\mathscr{W}^{\prime}$

$$
\begin{aligned}
\mathrm{X} & =\left(\ldots \rightarrow 0 \rightarrow \mathrm{~A}^{p} \xrightarrow{f} \mathrm{~A}^{q} \rightarrow 0 \rightarrow \ldots\right) \\
\mathrm{Y} & =\left(\ldots \rightarrow 0 \rightarrow \mathrm{~A}^{p^{\prime}} \xrightarrow{g} \mathrm{~A}^{q^{\prime}} \rightarrow \mathrm{o} \rightarrow \ldots\right) \\
\text { such that } \quad & \theta
\end{aligned}=\theta(\mathrm{X})-\theta(\mathrm{Y}) \quad \text { and } \quad \tau(\mathrm{X} \otimes \Lambda)=\tau(\mathrm{Y} \otimes \Lambda) .
$$

But the image of $\tau(\mathrm{X} \otimes \Lambda)=\tau(f \otimes \Lambda)$ under the boundary $\widetilde{\mathrm{K}}_{1}(\Lambda) \xrightarrow{\partial} \mathrm{K}_{0}(\mathbf{Z})$ is $q-p$ [9]. Then, after stabilization on X and Y , we may suppose

$$
p=p^{\prime} \quad \text { and } \quad q=q^{\prime}
$$

Let $\varphi \in \mathrm{GL}_{q}(\Lambda)$ be the map for $(f \otimes \Lambda) \circ(g \otimes \Lambda)^{-1}$. Since $\tau(f \otimes \Lambda)-\tau(g \otimes \Lambda)$ is zero, the class of $\varphi$ in $\mathrm{K}_{1}(\Lambda)$ is in the image of $\mathrm{K}_{1}(\mathbf{Z}) \rightarrow \mathrm{K}_{1}(\Lambda)$. Then, after a permutation on the basis of $\mathrm{A}^{q}$ (in X ) and after stabilization on X and Y , we may suppose that $\varphi$ lies in the commutator subgroup of $\mathrm{GL}_{q}(\Lambda)$ :

$$
\varphi=\prod_{i}\left[\varphi_{i}, \psi_{i}\right] .
$$

And we have

$$
\theta=\theta(\mathrm{X})-\theta(\mathrm{Y})=\theta(f)-\theta(g)=\theta(f \otimes \Lambda)-\theta(g \otimes \Lambda)=\theta(\varphi)
$$

whence

$$
\theta=\Sigma\left(\theta\left(\varphi_{i}\right)+\theta\left(\psi_{i}\right)-\theta\left(\varphi_{i}\right)-\theta\left(\psi_{i}\right)\right)=0 .
$$

This completes the proof.
Corollary (7.10). - The class of $\Lambda$-acyclic complexes in $\mathscr{W}$ is the class of $\Lambda$-acyclic complexes $\mathbf{C}$ such that the torsion of $\mathbf{C} \otimes \Lambda$ is in $\alpha$.

Now we prove lemmas (4.3) and (4.6).
Lemma (4.6) is actually the corollary (7.10).
Let $\tau \in \widetilde{\mathbf{K}}_{1}(\Lambda)$. By theorem (7.9), there exists a complex $\mathbf{C} \in \mathscr{W}^{\prime}$ such that $\tau$ is the torsion of $\mathbf{G} \otimes \Lambda$. Since $\mathbf{C}$ is splittable ( $(7.1)$ ), we can split $\mathbf{C}$ into $\Lambda$-acyclic complexes $\mathrm{C}_{i}$ of length two and we have $\tau=\Sigma \tau\left(\mathrm{C}_{i} \otimes \Lambda\right)$. If $\mathrm{C}_{i}$ is $\left(n_{i}+1\right)$-dimensional and the differential of $\mathrm{G}_{i}$ is $u_{i}$, we have:

$$
\tau=\Sigma(-1)^{n_{i}} \tau\left(u_{i} \otimes \Lambda\right)
$$

and lemma (4.3) follows.

## 8. The isomorphism theorem

Suppose now that A is a ring with involution and $\mathscr{W}$ is an exact symmetric class in $\mathscr{C}(\mathrm{A})$. The $\mathscr{W}$-localization of A is $(\Lambda, \alpha)$ and $\mathrm{A} \rightarrow \Lambda$ is a morphism of rings with involution.

The class of $\Lambda$-acyclic complexes in $\mathscr{C}(\mathrm{A})$ is denoted by $\mathscr{W}^{\prime}$ and the class of acyclic complexes in $\mathscr{C}(\Lambda)$ is denoted by $\mathscr{W}_{\Lambda}$.

We have a canonical map

$$
\varepsilon: \Gamma_{n}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right) \rightarrow \Gamma_{n}\left(\Lambda, \mathscr{W}_{\Lambda}\right) \simeq \mathrm{L}_{n}^{h}(\Lambda)
$$

In this section, we will prove that $\varepsilon$ is an isomorphism.
Lemma (8.1). - Let $\mathbf{C}$ (respectively $\Sigma$ ) be a p-dimensional and ( $p-2$ )-connected complex in $\mathscr{C}(\mathrm{A})$ (respectively $\mathscr{C}(\Lambda)$ ) and $f: \Sigma \rightarrow \mathbf{C} \otimes \Lambda$ be a map. Then there exist a p-dimensional complex $\Sigma^{\prime} \in \mathscr{C}(\mathrm{A})$, a homotopy equivalence $\varepsilon: \Sigma^{\prime} \otimes \Lambda \rightarrow \Sigma$ and a map $g: \Sigma^{\prime} \rightarrow \mathbf{C}$ such that $f \circ \varepsilon$ is homotopic to $g \otimes \Lambda$.

Proof. - Let us consider the modules $\Sigma_{p}, \Sigma_{p-1}$ as $p$-dimensional complexes $\mathrm{C}_{p}^{\prime} \otimes \Lambda$, $\mathrm{C}_{p-1}^{\prime} \otimes \Lambda$. The differential $d$ on $\Sigma$ is a map from $\mathrm{C}_{p}^{\prime} \otimes \Lambda$ to $\mathrm{C}_{p-1}^{\prime} \otimes \Lambda$. Then, by theorem (6.12), there exist a $p$-dimensional complex $\overline{\mathbf{C}} \in \mathscr{C}(\mathrm{A})$, a $\mathscr{W}^{\prime}$-equivalence $\bar{\varepsilon}: \overline{\mathrm{C}} \rightarrow \mathrm{C}_{p}^{\prime}$ and a morphism $g: \overline{\mathrm{C}} \rightarrow \mathrm{C}_{p-1}^{\prime}$ such that $g \otimes \Lambda$ is homotopic to $d \circ(\bar{\varepsilon} \otimes \Lambda)$.

Let M be the mapping cone of $g$. The $\mathscr{W}^{\prime}$-equivalence $\bar{\varepsilon}$ induces a homotopy equivalence $\varepsilon^{\prime}: M \otimes \Lambda \rightarrow \Sigma$. Moreover $M$ is $p$-dimensional and $\mathbf{C \otimes \Lambda}$ is ( $p-2$ )connected. Then by (6.12), there exist a $p$-dimensional complex $\Sigma^{\prime} \in \mathscr{C}(\mathrm{A})$, a $\mathscr{W}^{\prime}$-equivalence $\varepsilon^{\prime \prime}: \Sigma^{\prime} \rightarrow \mathrm{M}$ and a morphism $g: \Sigma^{\prime} \rightarrow \mathrm{C}$ such that $f \circ \varepsilon^{\prime} \circ\left(\varepsilon^{\prime \prime} \otimes \Lambda\right)$ is homotopic to $g \otimes \Lambda$. The result follows.

Lemma (8.2). - Let $\mathbf{C}$ be a finite A -complex such that $\mathrm{H}^{\mathbf{i}}(\mathrm{C}, \Lambda)$ vanishes for $i>p$ and let $\varphi \in \mathbf{B}(\mathbf{C} \otimes \Lambda)$ be a bilinear form such that

$$
\partial^{0} \varphi \leq-2 p+1, \quad d \varphi=0
$$

Then there exist a complex $\mathbf{C}^{\prime} \in \mathscr{C}(\mathbf{A})$ with $\operatorname{dim} \mathbf{C}^{\prime}=\operatorname{dim} \mathbf{C}$, a $\mathscr{W}^{\prime}$-equivalence $\varepsilon: \mathbf{C}^{\prime} \rightarrow \mathbf{C}$ and a bilinear form $\varphi^{\prime} \in \mathbf{B}\left(\mathbf{C}^{\prime}\right)$ such that $d \varphi^{\prime}=0$ and $\varepsilon^{*}(\varphi)-\varphi^{\prime} \otimes \Lambda$ is a boundary.

Proof. - By theorem (6.12), there exist a complex $\mathrm{C}^{\prime} \in \mathscr{C}(\mathrm{A})$ with $\operatorname{dim} \mathrm{C}^{\prime}=\operatorname{dim} \mathrm{C}$, a $\mathscr{W}^{\prime}$-equivalence $\varepsilon: \mathrm{C}^{\prime} \rightarrow \mathrm{C}$ and a morphism $g: \mathrm{C}^{\prime} \rightarrow \widehat{\mathrm{C}}$ such that $\varphi \circ(\varepsilon \otimes \Lambda)$ is homotopic to $\Lambda \otimes g$. Then $\varphi^{\prime}=\hat{\varepsilon} g$ is the desired form.

Lemma (8.3). - Let C be a finite A-complex such that $\mathrm{H}^{i}(\mathrm{C}, \Lambda)$ vanishes for $i>p$ and let $\varphi \in \mathbf{B}(\mathbf{C})$ be a bilinear form such that

$$
\partial^{0} \varphi \leq-2 p, \quad d \varphi=0
$$

Then, if $\varphi \otimes \Lambda$ is a boundary, there exist a complex $\mathbf{C}^{\prime} \in \mathscr{C}(\mathrm{A})$ with $\operatorname{dim} \mathbf{C}^{\prime}=\operatorname{dim} \mathbf{C}$ and a $\mathscr{W}^{\prime}$-equivalence $\varepsilon: \mathrm{C}^{\prime} \rightarrow \mathbf{C}$ such that $\varepsilon^{*}(\varphi)$ is a boundary.

Proof. - If $\varphi \otimes \Lambda$ is a boundary, $\varphi \otimes \Lambda$ is null homotopic and, by (6.12), there exist a complex $\mathrm{C}^{\prime} \in \mathscr{C}(\mathrm{A})$ with $\operatorname{dim} \mathrm{C}^{\prime}=\operatorname{dim} \mathrm{C}$ and a $\mathscr{W}^{\prime}$-equivalence $\varepsilon: \mathrm{C}^{\prime} \rightarrow \mathbf{C}$ such that $\varphi \circ \varepsilon$ is null homotopic. Then $\varepsilon^{*}(\varphi)=\hat{\varepsilon} \circ \varphi \circ \varepsilon$ is a boundary.

Theorem (8.4). - The morphism $\varepsilon: \Gamma_{n}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right) \rightarrow \mathrm{L}_{n}^{h}(\Lambda)$ is an isomorphism.

$$
\text { Proof. - Suppose } n=-2 p \text { or } n=-2 p+\mathrm{I} \text {, and let } \sigma \in \mathrm{L}_{n}^{h}(\Lambda) \text {. }
$$

By lemma (3.6), $\sigma$ is represented by a $\mathscr{W}_{\Lambda}$-non singular quadratic $n$-complex ( $\mathbf{C}, q$ ) where C is concentrated in dimension $p$ (and $p-\mathrm{I}$ if $n$ is odd).

By lemma (8.1), there exist a $p$-dimensional complex $\mathrm{C}^{\prime} \in \mathscr{C}(\mathrm{A})$ and a homotopy equivalence from $\mathrm{C}^{\prime} \otimes \Lambda$ to $\mathbf{C}$. Then $\sigma$ is represented by $\left(\mathrm{C}^{\prime} \otimes \Lambda, q^{\prime}\right)$. Since $\mathrm{C}^{\prime}$ is $p$-dimensional, $q^{\prime}$ is the class of $e_{0} \otimes \varphi_{0}+e_{1} \otimes \varphi_{1}$ and we have

$$
d \varphi_{0}+\varphi_{1}-\hat{\varphi}_{1}=0, \quad d \varphi_{1}=0
$$

By lemma (8.2), we may suppose that $\varphi_{1}$ has the form $\psi_{1} \otimes \Lambda, \psi_{1} \in \operatorname{B}\left(\mathbf{C}^{\prime}\right)$ and $d \psi_{1}$ is zero. Then $\left(\psi_{1}-\hat{\psi}_{1}\right) \otimes \Lambda$ is a boundary and, by lemma (8.3), we may suppose that $\psi_{1}-\hat{\psi}_{1}$ is a boundary $d \xi$.

Now, $\varphi_{0}+\xi \otimes \Lambda$ is a cycle and, by (8.2), we may suppose that

$$
\varphi_{0}+\xi \otimes \Lambda=\varphi^{\prime} \otimes \Lambda+d \eta
$$

where $\varphi^{\prime}$ is a cycle in $\mathrm{B}\left(\mathrm{C}^{\prime}\right)$ and $\eta \in \mathrm{B}\left(\mathrm{C}^{\prime} \otimes \Lambda\right)$. Then, we have

$$
e_{0} \otimes \varphi_{0}+e_{1} \otimes \varphi_{1}=\left(e_{0} \otimes\left(\varphi^{\prime}-\xi\right)+e_{1} \otimes \psi_{1}\right) \otimes \Lambda+d\left(e_{0} \otimes \eta\right) .
$$

Moreover $e_{0} \otimes\left(\varphi^{\prime}-\xi\right)+e_{1} \otimes \psi_{1}$ is a cycle and represents a $\mathscr{W}^{\prime}$-non singular quadratic $n$-form over $\mathrm{C}^{\prime}$. Then the morphism $\varepsilon$ is surjective.

Now let $\sigma^{\prime} \in \Gamma_{n}\left(\mathrm{~A}, \mathscr{W}^{\prime}\right)$ be an element in Ker $\varepsilon$. By lemma (3.6), $\sigma^{\prime}$ is represented by a $\mathscr{W}^{\prime}$-non singular quadratic $n$-complex ( $\mathrm{C}, q$ ) where C is a complex in $\mathscr{C}(\mathrm{A})$ concentrated in dimension $p$ (and $p-\mathrm{I}$ if $n$ is odd).

Since $\varepsilon \sigma^{\prime}$ is zero, $(\mathbf{C} \otimes \Lambda, q \otimes \Lambda)$ is cobordant to zero and, by lemmas (3.7) and (3.8), there exists a $\mathscr{W}_{\Lambda}$-non singular quadratic ( $n+1$ )-pair ( $\Sigma \rightarrow \mathrm{G} \otimes \Lambda, u$ ) such that $q$ is the boundary of $u$ and $\Sigma_{i}$ vanishes for $i \neq p, p-\mathrm{I}$.

By lemma (8.1), we may suppose that the morphism $\Sigma \rightarrow \mathbf{C} \otimes \Lambda$ is the morphism $g \otimes \Lambda: \Sigma^{\prime} \otimes \Lambda \rightarrow \mathbf{C} \otimes \Lambda$, where $\Sigma^{\prime}$ is a $p$-dimensional complex in $\mathscr{C}(\mathrm{A})$. The quadratic form $u$ is represented by

$$
e_{0} \otimes \psi_{0}+e_{1} \otimes \psi_{1}+e_{2} \otimes \psi_{2}, \quad \psi_{i} \in \mathrm{~B}\left(\Sigma^{\prime}\right),
$$

and we have

$$
\begin{aligned}
& d \psi_{0}+\psi_{1}-\hat{\psi}_{1}=\hat{g} \varphi_{0} g \otimes \Lambda \\
& -d \psi_{1}+\psi_{2}+\hat{\psi}_{2}=\hat{g} \varphi_{1} g \otimes \Lambda \\
& d \psi_{2}=0
\end{aligned}
$$

where $e_{0} \otimes \varphi_{0}+e_{1} \otimes \varphi_{1}$ represents $q$.
By lemma (8.2), we may suppose that

$$
\psi_{2}=\psi_{2}^{\prime} \otimes \Lambda+d \xi_{1}, \quad d \psi_{2}^{\prime}=0
$$

and, after adding to $e_{0} \otimes \psi_{0}+e_{1} \otimes \psi_{1}+e_{2} \otimes \psi_{2}$ the boundary of $e_{2} \otimes \xi_{1}$, we have

$$
\psi_{2}=\psi_{2}^{\prime} \otimes \Lambda, \quad d \psi_{2}^{\prime}=0
$$

Then $\left(\hat{g} \varphi_{1} g-\psi_{2}^{\prime}-\hat{\psi}_{2}^{\prime}\right) \otimes \Lambda$ is a boundary and, by lemma (8.3), we may suppose that

$$
\hat{g} \varphi_{1} g=\psi_{2}^{\prime}+\widehat{\psi}_{2}^{\prime}+d \eta_{1} .
$$

Since $\psi_{1}+\eta_{1} \otimes \Lambda$ is a cycle, we may suppose, by lemma (8.2), that

$$
\psi_{1}+\eta_{1} \otimes \Lambda=\psi_{1}^{\prime} \otimes \Lambda+d \xi_{0}, \quad d \psi_{1}^{\prime}=0,
$$

and, after adding to $e_{0} \otimes \psi_{0}+e_{1} \otimes \psi_{1}+e_{2} \otimes \psi_{2}$ the boundary of $-e_{1} \otimes \xi_{0}$, we may suppose that

$$
\psi_{1}+\eta_{1} \otimes \Lambda=\psi_{1}^{\prime} \otimes \Lambda, \quad d \psi_{1}^{\prime}=0
$$

Then, we have

$$
d \psi_{0}+\left(\psi_{1}^{\prime}-\eta_{1}-\hat{\psi}_{1}^{\prime}+\hat{\eta}_{1}\right) \otimes \Lambda=\hat{g} \varphi_{0} g \otimes \Lambda .
$$

Let $\psi$ be the form $\hat{g} \varphi_{0} g-\psi_{1}^{\prime}+\eta_{1}+\hat{\psi}_{1}^{\prime}-\hat{\eta}_{1}$. The bilinear form $\psi$ is a cycle of degree $n$ and $\psi \otimes \Lambda$ is a boundary. Moreover, by Poincaré duality, $\mathrm{H}^{i}\left(\Sigma^{\prime}, \Lambda\right)$ vanishes for $i>-n-p$. Then lemma (8.3) holds and we may suppose that

$$
\hat{g} \varphi_{0} g-\psi_{1}^{\prime}+\eta_{1}+\hat{\psi}_{1}^{\prime}-\hat{\eta}_{1}=d \eta_{0} .
$$

So $\psi_{0}-\eta_{0} \otimes \Lambda$ is a cycle and, by (8.2), we may suppose that

$$
\psi_{0}-\eta_{0} \otimes \Lambda=\psi_{0}^{\prime} \otimes \Lambda+d \xi_{-1}, \quad d \psi_{0}^{\prime}=0
$$

and, after adding to $e_{0} \otimes \psi_{0}+e_{1} \otimes \psi_{1}+e_{2} \otimes \psi_{2}$ the boundary of $e_{0} \otimes \xi_{-1}$, we may suppose that

$$
\psi_{0}-\eta_{0} \otimes \Lambda=\psi_{0}^{\prime} \otimes \Lambda .
$$

Now it is easy to check that

$$
e_{0} \otimes \psi_{0}+e_{1} \otimes \psi_{1}+e_{2} \otimes \psi_{2}=\left[e_{0} \otimes\left(\eta_{0}+\psi_{0}^{\prime}\right)+e_{1} \otimes\left(-\eta_{1}+\psi_{1}^{\prime}\right)+e_{2} \otimes \psi_{2}^{\prime}\right] \otimes \Lambda
$$

and

$$
d\left[e_{0} \otimes\left(\eta_{0}+\psi_{0}^{\prime}\right)+e_{1} \otimes\left(-\eta_{1}+\psi_{1}^{\prime}\right)+e_{2} \otimes \psi_{2}^{\prime}\right]=g^{*}\left(e_{0} \otimes \varphi_{0}+e_{1} \otimes \varphi_{1}\right) .
$$

Then $e_{0} \otimes\left(\eta_{0}+\psi_{0}^{\prime}\right)+e_{1} \otimes\left(-\eta_{1}+\psi_{1}^{\prime}\right)+e_{2} \otimes \psi_{2}^{\prime}$ represents a $\mathscr{W}^{\prime}$-non singular quadratic $(n+1)$-form $v$ over $\Sigma^{\prime} \rightarrow \mathrm{C}$ with boundary $q$. So $\sigma^{\prime}$ is zero and $\varepsilon$ is injective.

## 9. Some results about $\Lambda$ and $L_{n}(\Lambda)$

Throughout this section, we assume that $\mathrm{A} \rightarrow \mathrm{B}$ is a ring homomorphism and $\beta$ is a subgroup of $\widetilde{K}_{1}(B)$.

The class of finite A-complexes $C$ such that $\mathbf{C} \otimes B$ is acyclic with torsion in $\beta$ is denoted by $\mathscr{W}^{\beta}$, and the $\mathscr{W}^{\beta}$-localization of A is denoted by $(\Lambda, \alpha)$.

Proposition (9.1). - Let u be a matrix with entries in $\Lambda$. Then, if $u \otimes \mathrm{~B}$ is invertible, $u$ is invertible too.

Proof. - Let $u$ be a matrix with entries in $\Lambda$. If we denote by A the o-dimensional complex $\ldots \rightarrow 0 \rightarrow \mathrm{~A} \rightarrow \mathrm{o} \rightarrow \ldots, u$ is a morphism $\mathrm{A}^{p} \otimes \Lambda \rightarrow \mathrm{~A}^{q} \otimes \Lambda$ and, by theo-
rem (6.12), there exist a o-dimensional complex $\overline{\mathrm{C}} \in \mathscr{C}(\mathrm{A})$, a ( $\left.\mathscr{W}^{\beta}\right)_{0}^{s}$-equivalence $\varepsilon: \overline{\mathrm{C}} \rightarrow \mathrm{A}^{p}$ and a morphism $g: \overline{\mathrm{C}} \rightarrow \mathrm{A}^{q}$ such that $g \otimes \Lambda$ is homotopic to $u_{\circ}(\varepsilon \otimes \Lambda)$.

Let K be the homotopy kernel of $\varepsilon$. Since K is $\mathscr{W}_{0}^{\beta}$-splittable, there exist a (-1)-dimensional complex $\mathrm{K}^{\prime} \in \mathscr{W}_{0}^{\beta}$ and a (-2)-connected morphism $f: \mathrm{K}^{\prime} \rightarrow \mathrm{K}$. The composite map $\mathrm{K}^{\prime} \rightarrow \mathrm{K} \rightarrow \overline{\mathrm{C}}$ is (-2)-connected. Denote by $\mathrm{C}^{\prime}$ its mapping cone. The complex $\mathrm{C}^{\prime}$ lies in $\mathscr{W}_{0}^{\beta}$ and has the simple homotopy type of a complex $\mathbf{C}^{\prime \prime}$ such that $\mathrm{C}_{i}^{\prime \prime}$ vanishes for $i \neq 0,-\mathrm{I}$. Moreover $\varepsilon$ and $g$ factorize through $\mathrm{C}^{\prime \prime}$ and we get two morphisms $\varepsilon^{\prime}: \mathrm{C}^{\prime \prime} \rightarrow \mathrm{A}^{p}$ and $g^{\prime}: \mathrm{C}^{\prime \prime} \rightarrow \mathrm{A}^{q}$ such that $g^{\prime} \otimes \Lambda$ is homotopic to $u \circ\left(\varepsilon^{\prime} \otimes \Lambda\right)$.

But $u \otimes \mathrm{~B}$ is invertible, then $g^{\prime} \otimes \mathrm{B}$ is a homotopy equivalence and the mapping cone of $g^{\prime}$ is B -acyclic and lies in $\mathscr{W}_{0}^{\beta}$. Since the length of this mapping cone is $2, g^{\prime}$ is a $\left(\mathscr{W}^{\beta}\right)_{0}^{s}$-equivalence. Then, by (7.I), $g^{\prime}$ is a $\Lambda$-homology equivalence, and $u$ is an isomorphism.
(9.2) Proof of theorem (1.13)

If $u$ is a matrix with entries in A , denote by $\mathrm{M}(u)$ the I -dimensional complex $\ldots \rightarrow 0 \rightarrow \mathrm{~A}^{p} \xrightarrow{u} \mathrm{~A}^{q} \rightarrow 0 \rightarrow \ldots$

The set $\Sigma$ is the set of matrices $u$ such that $(\mathrm{M}(u) \oplus \Sigma \mathrm{M}(u)) \otimes \mathrm{B}$ is acyclic with torsion in $\beta$. But $\mathrm{M}(u) \oplus \Sigma \mathrm{M}(u)$ is B -acyclic if and only if $\mathrm{M}(u)$ is B -acyclic. Moreover if $\mathrm{M}(u)$ is B -acyclic, we have

$$
\tau[\mathrm{M}(u) \otimes \mathrm{B} \oplus \mathrm{\Sigma} \mathrm{M}(u) \otimes \mathrm{B}]=\mathrm{o}
$$

Then $\Sigma$ is the set of matrices $u$ such that $u \otimes \mathrm{~B}$ is invertible and $\mathrm{A} \rightarrow \Lambda$ is the localization of $\mathrm{A} \rightarrow \mathrm{B}$.

Now let $\tau$ be an element of $\widetilde{\mathrm{K}}_{1}(\Lambda)$. By lemma (4.3), there exists a finite A-complex $\mathbf{C}$ such that $\mathbf{C} \otimes \Lambda$ is acyclic with torsion $\tau$. Then, by lemma ( $7 \cdot 10$ ), $\tau$ lies in $\alpha$ if and only if C lies in $\mathscr{W}^{\beta}$. But the torsion of $\mathrm{C} \otimes \mathrm{B}$ is the image of $\tau$ by the morphism $\varepsilon: \Lambda \rightarrow B$. Hence $\alpha$ is the inverse image of $\beta$ under $\varepsilon$.

Now suppose $\varepsilon$ is onto, and let $\mathbf{C} \in \mathscr{W}^{\beta}$. The complex $\mathbf{C} \otimes \mathbf{B}$ is acyclic and the identity is a homotopy: $\mathrm{I}=d \circ k+k \circ d$.

But $\mathbf{C} \otimes \Lambda \rightarrow \mathbf{C} \otimes \mathbf{B}$ is onto and we can lift $k$ in a map $k^{\prime}$ from $\mathbf{C} \otimes \Lambda$ to itself. The morphism $d \circ k^{\prime}+k^{\prime} \circ d$ is invertible after tensorization by B. Then, by (9.1), $d \circ k^{\prime}+k^{\prime} \circ d$ is an isomorphism and $\mathbf{C} \otimes \Lambda$ is acyclic.
(9.3) Proof of Proposition (1.15)

Let $B_{0} \subset B_{1} \subset B_{2} \subset \ldots$ be subrings of $B$ defined by:
(i) $\mathrm{B}_{0}$ is the image of $\mathrm{A} \rightarrow \mathrm{B}$;
(ii) for any $n \geq 0, \mathrm{~B}_{n+1}$ is generated by $\mathrm{B}_{n}$ and the inverses of the units of B contained in $\mathrm{B}_{n}$.

Denote by $\mathbf{B}^{\prime}$ the image of $\Lambda \rightarrow \mathbf{B}$. The subring $\mathbf{B}^{\prime}$ contains $A$ and, by ( 9.1 ), any unit of B contained in $\mathrm{B}^{\prime}$ is a unit of $\mathrm{B}^{\prime}$. Then $\mathrm{B}^{\prime}$ contains all the rings $\mathrm{B}_{n}$.

As a corollary of (9.I), we have:
Lemma (9.4). - If $\Lambda \rightarrow \mathrm{B}$ is onto, $\widetilde{\mathrm{K}}_{\mathbf{1}}(\Lambda) \rightarrow \widetilde{\mathrm{K}}_{\mathbf{1}}(\mathrm{B})$ is onto.
From now on, we will suppose that $A \rightarrow B$ is a morphism of rings with involution and that $\beta$ is stable under the involution. Then $\mathscr{W}^{\beta}$ is symetric and $\Lambda$ has an involution. We suppose also that $\Lambda \rightarrow B$ is onto.

Theorem (9.5). - If $n$ is even, the morphism $\mathrm{L}_{n}^{\alpha}(\Lambda) \rightarrow \mathrm{L}_{n}^{\beta}(\mathrm{B})$ is epic. If $n$ is odd, this morphism is monic.

Proof. - By lemma (9.4), the relative group $\mathrm{L}_{n}^{\alpha, \beta}(\Lambda \rightarrow B)$ does not depend on $\beta$. Then it suffices to prove the theorem in the case $\beta=\widetilde{\mathrm{K}}_{1}(\mathrm{~B})$.

Let $n=2 p$. An element $u \in \mathrm{~L}_{2 p}^{h}(\mathrm{~B})$ is represented by a hermitian ( -I$)^{p_{-}}$ form ( $H, \lambda, \mu$ ) such that the induced map $\tilde{\lambda}: H \rightarrow \hat{H}$ is an isomorphism. Since $H$ is free over $B$ and $\Lambda \rightarrow B$ is epic, there exists a hermitian ( -1$)^{p}$-form ( $H^{\prime}, \lambda^{\prime}, \mu^{\prime}$ ) such that $\mathrm{H}^{\prime}$ is free over $\Lambda$,

$$
\mathrm{H}^{\prime} \otimes \mathbf{B}=\mathrm{H}, \quad \lambda^{\prime} \otimes \mathbf{B}=\lambda, \quad \mu^{\prime} \otimes \mathbf{B}=\mu
$$

Then, by lemma (9.I), $\lambda^{\prime}$ induces an isomorphism from $H^{\prime}$ to $\hat{H}^{\prime}$ and ( $H^{\prime}, \lambda^{\prime}, \mu^{\prime}$ ) represents an element $v \in \mathbb{L}_{2 p}^{h}(\Lambda)$ such that $\varepsilon_{*}(v)=u$.

Let now $n=2 p+\mathrm{I}$. An element $v \in \mathrm{~L}_{2 p+1}^{h}(\Lambda)$ is represented by an isometry between two standard kernel K and $\mathrm{K}^{\prime}$. If $v$ is sent to zero in $\mathrm{L}_{2 p+1}^{h}(\mathrm{~B}), \mathrm{K}=\mathrm{K}^{\prime}$ and $g \otimes B$ is an element of $\operatorname{RU}^{h}(\mathrm{~B})$ (with the notations of [io]).

Consider the following diagram:

By lemma (9.1), $a$ and $c$ are surjective. Then $b$ is epic and the morphism $\operatorname{RU}^{h}(\Lambda) \rightarrow \operatorname{RU}^{h}(\mathrm{~B})$ is epic too. Hence $v$ can be represented by an isometry $f$ such that $f \otimes \mathrm{~B}$ is the identity map.

Let $\mathrm{H} \oplus \hat{\mathrm{H}}$ be the standard kernel K . The isometry $f$ is defined by

$$
f(x, y)=(x+a(x)+b(y), y+c(x)+d(y)), \quad \forall x \in \mathrm{H}, y \in \hat{\mathrm{H}}
$$

and $a \otimes \mathrm{~B}, b \otimes \mathrm{~B}, c \otimes \mathrm{~B}, d \otimes \mathrm{~B}$ vanish. By (9.1), $\mathrm{I}+a$ is invertible and, after compo$\operatorname{sing} f$ with an element of $\mathrm{GL}(\Lambda)$, we may as well suppose that $a$ is zero.

Since $f$ is an isometry, it is easy to see that the map $g$ defined by

$$
g(x, y)=(x, y-c(x))
$$

is an isometry leaving each element of $\hat{\mathrm{H}}$ fixed and $g$ lies in $\operatorname{RU}^{h}(\Lambda)$. We have

$$
g \circ f(x, y)=(x+b(y), y+d(y)-c \circ b(y)) .
$$

But $\mathrm{I}+d-c \circ d$ is invertible and there is an isometry $h \in \operatorname{RU}^{h}(\Lambda)$ such that

$$
h \circ g \circ f(x, y)=\left(x+a^{\prime}(x)+b^{\prime}(y), y\right) .
$$

It is easy to see that $a^{\prime}$ is zero and $h \circ g \circ f$ lies in $\operatorname{RU}^{h}(\Lambda)$. Therefore V is zero.
Theorem (9.6). - The relative group $\mathrm{L}_{2 p+1}^{h}(\Lambda \rightarrow \mathrm{~B})$ is the group of equivalence classes of pairs $(\mathrm{H}, \mathrm{K})$ where H is a hermitian $(-\mathrm{I})^{p}$-form over $\Lambda$ and K a subkernel of $\mathrm{H} \otimes \mathrm{B}$, subject to the following relation:
$(\mathrm{H}, \mathrm{K})$ is equivalent to $\left(\mathrm{H}^{\prime}, \mathrm{K}^{\prime}\right)$ if there exist two $\Lambda$-kernels $\mathrm{H}_{0}$ and $\mathrm{H}_{0}^{\prime}$ with subkernels $\mathrm{S}_{0}$ and $\mathrm{S}_{0}^{\prime}$ and an isometry $\varphi: \mathrm{H} \oplus \mathrm{H}_{0} \rightarrow \mathrm{H}^{\prime} \oplus \mathrm{H}_{0}^{\prime}$ such that

$$
\varphi\left(\mathrm{K} \oplus \mathrm{~S}_{0} \otimes \mathrm{~B}\right)=\mathrm{K}^{\prime} \oplus \mathrm{S}_{0}^{\prime} \otimes \mathrm{B}
$$

Proof. - By Wall ([ro], p. 72), $\mathrm{L}_{2 p+1}^{h}(\Lambda \rightarrow \mathrm{~B})$ is generated by such pairs. Moreover ( $\mathrm{H}, \mathrm{K}$ ) and ( $\mathrm{H}^{\prime}, \mathrm{K}^{\prime}$ ) represent the same element in $\mathrm{L}_{2 p+1}^{h}(\Lambda \rightarrow B)$ if there exist two kernels $\overline{\mathrm{H}}_{0}$ and $\mathrm{H}_{0}^{\prime}$ with subkernels $\overline{\mathrm{S}}_{0}$ and $\overline{\mathrm{S}}_{0}^{\prime}$ and an isometry

$$
\bar{\varphi}: \mathrm{H} \oplus \overline{\mathrm{H}}_{0} \oplus-\mathrm{H}^{\prime} \rightarrow \mathrm{H}_{0}^{\prime}
$$

such that any automorphism $\bar{\psi}$ taking $\overline{\mathrm{S}}_{0}^{\prime} \otimes \mathbf{B}$ to $\bar{\varphi}\left(\mathrm{K} \oplus \overline{\mathrm{S}}_{0} \otimes \mathbf{B} \oplus \mathrm{~K}^{\prime}\right)$ lies in $\mathrm{RU}^{h}(\mathbf{B})$. But the map $\operatorname{RU}^{h}(\Lambda) \rightarrow \operatorname{RU}^{h}(\mathbf{B})$ is epic (see the proof of ( $9 \cdot 5$ )). Hence we can lift $\bar{\psi}$ to an automorphism $\psi$ on $\mathrm{H}_{0}^{\prime}$.

Let $\mathrm{S}_{0}^{\prime}$ be the subkernel $\psi\left(\overline{\mathrm{S}}_{0}^{\prime}\right)$. We have an isometry

$$
\varphi: \mathrm{H} \oplus \overline{\mathrm{H}}_{0} \oplus-\mathrm{H}^{\prime} \oplus \mathrm{H}^{\prime} \rightarrow \mathrm{H}^{\prime} \oplus \mathrm{H}_{0}^{\prime}
$$

taking $K \oplus \bar{S}_{0} \otimes B \oplus K^{\prime} \oplus K^{\prime}$ to $K^{\prime} \oplus S_{0}^{\prime} \otimes B$.
On the other hand, the diagonal $\overline{\mathrm{K}}$ is a subkernel of $-\mathrm{H}^{\prime} \oplus \mathrm{H}^{\prime}$ and there exists an automorphism in $\mathrm{RU}^{h}(\mathrm{~B})$ taking $\overline{\mathrm{K}} \otimes \mathrm{B}$ to $\mathrm{K}^{\prime} \oplus \mathrm{K}^{\prime}$. By lifting this automorphism in $\mathrm{RU}^{h}(\Lambda)$ we get an automorphism $f$ and $f(\overline{\mathrm{~K}})$ is a subkernel of $-\mathrm{H}^{\prime} \oplus \mathrm{H}^{\prime}$ such that $f(\overline{\mathrm{~K}}) \otimes \mathrm{B}=\mathrm{K}^{\prime} \oplus \mathrm{K}^{\prime}$. Let $\mathrm{H}_{0}$ be the kernel $\overline{\mathrm{H}}_{0} \oplus-\mathrm{H}^{\prime} \oplus \mathrm{H}^{\prime}$ with subkernel $\mathrm{S}_{0}=\overline{\mathrm{S}_{0}} \oplus f(\overline{\mathrm{~K}})$. Then $\varphi$ is an isometry taking $\mathrm{K} \oplus \mathrm{S}_{0} \otimes \mathrm{~B}$ to $\mathrm{K}^{\prime} \oplus \mathrm{S}_{0}^{\prime} \otimes \mathrm{B}$.

Now, consider the following question: Under what conditions is the map $\varepsilon: \Lambda \rightarrow B$ an isomorphism? To study this problem, it is convenient to use the following definitions:

An A-module $\mathbf{M}$ is called B -perfect if $\mathrm{M} \otimes \mathrm{B}$ is zero; it is called locally B -perfect if any element in $M$ is contained in a finitely generated B-perfect submodule.

Theorem (9.7). - Suppose the kernel of $\mathrm{A} \rightarrow \mathrm{B}$ is locally B -perfect and B is the localization of $\operatorname{Im}(\mathrm{A} \rightarrow \mathrm{B})$ with respect to a multiplicative subset of the center. Then the morphism $\varepsilon: \Lambda \rightarrow \mathbf{B}$ is an isomorphism.

Proof. - Let $a \in \operatorname{Ker}(\mathbf{A} \rightarrow \mathbf{B})$ and suppose that $a$ is contained in a finitely generated B-perfect submodule I. Let us choose a free resolution of I

$$
\mathrm{C} \xrightarrow{t} \mathrm{~A}^{n} \rightarrow \mathrm{I} \rightarrow \mathrm{o} .
$$

Since I is B-perfect, $f \otimes \mathrm{~B}$ is epic and has a section $s$. But $\Lambda \rightarrow B$ is epic and we can lift $s$ to a morphism $g: \Lambda^{n} \rightarrow \mathbf{G} \otimes \Lambda$. By (9.I), $f \otimes \Lambda \circ g$ is an isomorphism and $f \otimes \Lambda$ is epic. Hence I is $\Lambda$-perfect and the composite map $\mathrm{I} \rightarrow \mathrm{A} \rightarrow \Lambda$ is zero. Then $\mathrm{A} \rightarrow \mathrm{B}$ and $\mathrm{A} \rightarrow \Lambda$ have the same kernel K .

Now it is easy to see that the maps $A / K \rightarrow B$ and $A / K \rightarrow \Lambda$ have the same universal property and $\varepsilon: \Lambda \rightarrow B$ is an isomorphism.

This theorem is in fact a generalization of a theorem of Hausmann [3] proved also in [6] and [8], theorem (1.4).

Finally, we will give an example of computation.
Let $\mathrm{D}_{2 n}$ be the dihedral group of order $2 n$ ( $n$ odd) and let $\mathbf{Z D}_{2 n} \rightarrow \mathbf{Z}$ be the evaluation map. The group $D_{2 n}$ is not perfect and not nilpotent, then we cannot use the techniques of Hausmann or Smith in order to compute the group $\Gamma_{*}\left(\mathbf{Z D}_{2 n} \rightarrow \mathbf{Z}\right)$.

Theorem (9.8). - We have the isomorphisms

$$
\Gamma_{*}\left(\mathbf{Z} D_{2 n} \rightarrow \mathbf{Z}\right) \xrightarrow{\sim} \Gamma_{*}(\mathbf{Z}[\mathbf{Z} / 2] \rightarrow \mathbf{Z}) \xrightarrow{\sim} \mathrm{L}_{*}^{h}(\Lambda)
$$

where $\Lambda$ is the pull back of rings

Proof. - The group $\mathrm{D}_{2 n}$ is generated by $t$ and $\tau$ with the following relations:

$$
t^{n}=\mathrm{I}, \quad \tau^{2}=\mathrm{I}, \quad \tau t=t^{-1} \tau
$$

Let $\mathbf{Z D}_{2 n} \rightarrow \Lambda$ be the localization of $\mathbf{Z D}_{2 n} \rightarrow \mathbf{Z}$ and let $x$ and $y$ be the images of $t$ and $\tau$ in $\Lambda$. We have

$$
\left[\frac{\mathrm{I}-n}{2}(\mathrm{I}+\tau)+\mathrm{I}+t+\ldots+t^{n-1}\right](\mathrm{I}-\tau)(\mathrm{I}-t)=0
$$

But $\frac{\mathrm{I}-n}{2}(\mathrm{I}+\tau)+\mathrm{I}+t+\ldots+t^{n-1}$ is sent to I in $\mathbf{Z}$ and

$$
\frac{\mathrm{I}-n}{2}(\mathrm{I}+y)+\mathrm{I}+x+\ldots+x^{n-1}
$$

is invertible. This implies that

$$
(\mathrm{I}-y)(\mathrm{I}-x)=0
$$

On the other hand, $\mathbf{Z D}_{2 n} \rightarrow \Lambda$ is a morphism of rings with involution. So we have:

$$
(\mathrm{r}-y)(\mathrm{r}-x)=\left(\mathrm{r}-x^{-1}\right)(\mathrm{r}-y)=0 \Rightarrow(\mathrm{r}-x)(\mathrm{r}-y)=0 .
$$

And $x$ and $y$ commute. Then:

$$
y x=x^{-1} y=x y \Rightarrow x=1 .
$$

Hence $t$ is sent to I in $\Lambda$ and $\Lambda$ is the localization of $\mathbf{Z}[\mathbf{Z} / 2] \rightarrow \mathbf{Z}$. But $\mathbf{Z}[\mathbf{Z} / 2]$ is commutative and $\Lambda$ is the localization $S^{-1} \mathbf{Z}[\mathbf{Z} / 2]$ where $S$ is the set of elements $a+b \tau \in \mathbf{Z}[\mathbf{Z} / 2]$ with $a+b=\mathrm{I}$. Then it is easy to see that $\Lambda$ is the subring of $\mathbf{Z}_{(2)}[\mathbf{Z} / 2]$ defined by

$$
\Lambda=\left\{a+b \tau, a, b \in \mathbf{Z}_{(2)} \text { and } a+b \in \mathbf{Z}\right\} .
$$
