TABLES DE LA FONCTION DE RÉPARTITION DE LA LOI DE WEIBULL

F. DOURGNON et J. REYROLLE
Société Nouvelle de Roulements

La fonction de répartition de la loi de Weibull de forme générale :

$$F(z) = \Pr(Z < z) = 1 - \exp \left[- \left(\frac{z - \gamma}{\eta} \right)^\beta \right],$$

peut, moyennant le changement d'échelle défini par :

$$X = \frac{Z - \gamma}{\eta}$$

se mettre sous la forme réduite :

$$F(x) = 1 - \exp(-x^\beta).$$

Les tables ci-après donnent les valeurs de $F(x)$ avec 4 décimales pour :

$$\begin{aligned} x &= 0,01 \dots (0,01) \dots\dots 2,50 \\ \beta &= 0,1 \dots (0,1) \dots\dots 3 \end{aligned}$$

et pour

$$x = 0,1 \dots (0,1) \dots\dots 2 \quad \text{et} \quad \beta = 3,10 \dots\dots (0,10) \dots\dots 4,00$$

Exemple : $\beta = 2,2, \quad x = 0,4 \quad F(x) = 0,1247.$

UTILISATION DES TABLES DE LA LOI DE WEIBULL pour résoudre par simulation certains problèmes de fiabilité.

La loi de Weibull est une loi très générale à laquelle s'ajustent un grand nombre de phénomènes d'apparition d'avaries.

γ = paramètre d'origine des temps ; il est égal à 0 dans la tabulation

η = paramètre d'échelle ; il est égal à 1 dans la tabulation

L'allure générale des courbes représentatives dépend du paramètre de forme β qui caractérise la façon dont évolue le taux instantané d'avarie avec le temps de service.

1/ $\beta > 1$ - Taux instantané d'avarie croissant

Le matériel s'use en service. La densité de probabilité d'avarie est représentée par une courbe unimodale, fortement dissymétrique pour les faibles valeurs de β , mais qui tend vers une courbe symétrique, d'allure gaussienne pour les fortes valeurs, et pratiquement pour $\beta > 3$.

2/ $0 < \beta < 1$ - Taux instantané d'avarie décroissant

Au lieu de s'user, le matériel se rode et s'adapte à son service. La densité de probabilité d'avarie est constamment décroissante.

3/ $\beta = 1$ - Taux instantané d'avarie constant

Cas limite de la loi exponentielle pour la densité de probabilité d'avarie.

A un type donné de matériel correspond, en général, une certaine valeur de β , liée au fait que le matériel a plus ou moins tendance à s'user ou au contraire à s'adapter à son service. Ainsi, pour le roulement, dans le cas assez général que constituent les conditions habituelles de fabrication, puis d'essais accélérés en laboratoire, β reste voisin de 1,4.

L'ajustement à la loi de Weibull et la valeur de β ayant été acquis par des essais antérieurs, la connaissance du paramètre d'échelle η détermine complètement la courbe de survie. Elle donne la vie moyenne, ainsi que le temps B_{10} par exemple au bout duquel 10 % du matériel aura cessé de servir.

Mais, la connaissance de la caractéristique B_{10} , ou de tout autre point de la courbe de survie, suffit pour avoir la courbe toute entière, autrement dit, pour juger de la valeur d'une fabrication dans des conditions de travail déterminées.

Pour avoir un point tel que B_{10} avec précision, il faudrait pouvoir essayer un échantillon très important. Or, on est limité par le nombre de machines d'essais dont on dispose et surtout pour la durée souvent fort longue nécessaire à entraîner l'avarie. On choisira donc un estimateur de cette caractéristique, par exemple le temps au bout duquel survient la 8ème défaillance dans un échantillon de 80, ou bien la moyenne des temps des premières avaries dans chacun des 10 échantillons de 8. Tout le problème consiste à connaître l'intervalle de confiance pour la caractéristique cherchée autour de cet estimateur.

La résolution mathématique de ce problème est très difficile. Une simulation, engendrant en nombre illimité, à partir de nombres au hasard, des échantillons de taille semblable à ceux qu'on peut mettre à l'essai et distribués suivant une loi de Weibull de paramètre β désiré, permet d'obtenir la distribution de l'estimateur avec la précision que l'on veut. D'où l'on déduit l'intervalle de confiance à un risque donné autour de l'estimateur.

C'est ce procédé qui a été utilisé par la S.N.R. pour définir un plan d'essais de fiabilité.
