ABSTRACT. – Let $p=\frac{2N}{N-2}$, $N\geqq 3$ be the limiting Sobolev exponent and $\Omega\subset\mathbb{R}^N$ open bounded set.

We show that for $f\in H^{-1}$ satisfying a suitable condition and $f\neq 0$, the Dirichlet problem:

$$\begin{cases} -\Delta u=|u|^{p-2}u+f & \text{on } \Omega \\ \quad u=0 & \text{on } \partial\Omega \end{cases}$$

admits *two* solutions u_0 and u_1 in $H_0^1(\Omega)$.

Also $u_0\geqq 0$ and $u_1\geqq 0$ for $f\geqq 0$.

Notice that, in general, this is not the case if $f=0$ (*see* [P]).

Key words : Semilinear elliptic equations, critical Sobolev exponent.

RÉSUMÉ. – Soit $p=\frac{2N}{N-2}$ l'exposant de Sobolev critique et $\Omega\subset\mathbb{R}^N$ un domaine borné.

Classification A.M.S. : 35 A 15, 35 J 20, 35 J 65.

(*) This research has been supported in part by NSF, Grant DMS – 9003149.

On montre que si $f \in H^{-1}$, $f \neq 0$ satisfait une certaine condition alors le problème de Dirichlet : $\Delta u = |u|^{p-2} u + f$ dans Ω et $u=0$ dans $\partial\Omega$, admet deux solutions u_0 et u_2 dans $H_0^1(\Omega)$. De plus $u_0 \geqq 0$ et $u_1 \geqq 0$ si $f \geqq 0$.
On remarque que ce n'est pas le cas, en général, si $f=0$ (*voir* [P]).

1. INTRODUCTION AND MAIN RESULTS

In a recent paper Brezis-Nirenberg (B.N.1] have considered the following minimization problem:

$$\inf_{u \in H, \|u\|_p = 1} \int_\Omega (|\nabla u|^2 - fu) \tag{1.1}$$

where $\Omega \subset \mathbb{R}^N$, is a bounded set, $H = H_0^1(\Omega)$, $f \in H^{-1}$ and $p = \dfrac{2N}{N-2}$, $N \geqq 3$ is the limiting exponent in the Sobolev embedding.

It is well known that the infinum in (1.1) is never achieved if $f=0$ (*cf.* [B]). In contrast, in [B.N.1] it is shown that for $f \neq 0$ this infinum is always achieved. (*See* also [C.S.] for previous related results.)

Motivated by this result we consider the functional:

$$I(u) = \frac{1}{2}\int_\Omega |\nabla u|^2 - \frac{1}{p}\int_\Omega |u|^p - \int_\Omega fu, \qquad u \in H;$$

whose critical points define weak solutions for the Dirichlet problem:

$$\left.\begin{aligned} -\Delta u &= |u|^{p-2} u + f \quad \text{on } \Omega \\ u &= 0 \quad \text{on } \partial\Omega. \end{aligned}\right\} \tag{1.2}$$

We investigate suitable minimization and minimax principles of mountain pass-type (*cf.* [A.R.]), and show how, for suitable f's, they produce critical values for I in spite of a possible failure of the Palais-Smale condition.

To start, notice that I is bounded from below in the manifold:

$$\Lambda = \{ u \in H : \langle I'(u), u \rangle = 0 \}$$

[here $\langle\ ,\ \rangle$ denotes the usual scalar product in $H = H_0^1(\Omega)$]. Thus a natural question to ask is whether or not I achieves a minimum in Λ.

We show that this is the case if f satisfies the following:

$$\int_\Omega fu \leqq c_N (\|\nabla u\|_2)^{(N+2)/2} \tag*{$(*)_0$}$$

$\forall u \in \mathrm{H}$, $\|u\|_p = 1$, where $c_\mathrm{N} = \dfrac{4}{\mathrm{N}-2}\left(\dfrac{\mathrm{N}-2}{\mathrm{N}+2}\right)^{(\mathrm{N}+2)/4}$. More precisely we have:

THEOREM 1. — *Let $f \neq 0$ satisfies $(*)_0$. Then*

$$\inf_{\Lambda} \mathrm{I} = c_0 \tag{1.3}$$

is achieved *at a point $u_0 \in \Lambda$ which is a critical point for* I *and $u_0 \geqq 0$ for $f \geqq 0$.*

In addition if f satisfies the more restrictive assumption:

$$\int_\Omega fu < c_\mathrm{N} (\|\nabla u\|_2)^{(\mathrm{N}+2)/2} \tag{$*$}$$

$\forall u \in \mathrm{H}$, $\|u\|_p = 1$, then u_0 is a *local minimum* for I. □

Notice that assumption $(*)$ certainly holds if

$$\|f\|_{\mathrm{H}^{-1}} \leqq c_\mathrm{N} \mathrm{S}^{\mathrm{N}/4}$$

where S is the best Sobolev constant (*cf.* [T]).

Also if $f=0$ Theorem 1 remains valid and gives the trivial solution $u_0 = 0$.

Moreover in the situation where u_0 is a local minimum for I, necessarily:

$$\|\nabla u_0\|_2^2 - (p-1)\|u_0\|_p^p \geqq 0 \tag{1.4}$$

This suggests to look at the following splitting for Λ:

$$\Lambda^+ = \{u \in \Lambda : \|\nabla u\|_2^2 - (p-1)\|u\|_p^p > 0\}$$
$$\Lambda_0 = \{u \in \Lambda : \|\nabla u\|_2^2 - (p-1)\|u\|_p^p = 0\}$$
$$\Lambda^- = \{u \in \Lambda : \|\nabla u\|_2^2 - (p-1)\|u\|_p^p < 0\}.$$

It turns out that assumption $(*)$ implies $\Lambda_0 = \{0\}$ (*see* Lemma 2.3 below). Therefore for $f \neq 0$ and (1.4) we obtain $u_0 \in \Lambda^+$ and consequently

$$c_0 = \inf_{\Lambda} \mathrm{I} = \inf_{\Lambda^+} \mathrm{I}.$$

So we are led to investigate a second minimization problem. Namely:

$$\inf_{\Lambda^-} \mathrm{I} = c_1. \tag{1.5}$$

In this direction we have:

THEOREM 2. — *Let $f \neq 0$ satisfies $(*)$. Then $c_1 > c_0$ and the infinum in* (1.5) *is achieved at a point $u_1 \in \Lambda^-$ which define a critical point for* I.

Furthermore $u_1 \geqq 0$ for $f \geqq 0$. □

Notice that the assumption $f \neq 0$ is *necessary* in Theorem 2. In fact for $f=0$ we have:

$$\operatorname{Inf}_{\Lambda^-} \mathrm{I} = \inf_{u \neq 0} \frac{1}{\mathrm{N}} \left[\frac{\|\nabla u\|_2^2}{\|u\|_p^2} \right]^{\mathrm{N}/2} = \frac{1}{\mathrm{N}} [\inf_{\|u\|_p=1} \|\nabla u\|_2^2]^{\mathrm{N}/2}$$

and the infinum in the right hand side is *never* achieved.

The proofs of Theorem 1 and Theorem 2 rely on the Ekeland's variational principle (*cf.* [A.E.]) and careful estimates inspired by these in [B.N.1].

As an immediate consequence of Theorems 1 and 2 we have the following for the Dirichlet problem (1.2).

THEOREM 3. — Problem (1.2) admits at least *two* weak solutions u_0, $u_1 \in \mathrm{H}_0^1(\Omega)$ for $f \neq 0$ satisfying $(*)$; and at least *one* weak solution for f satisfying $(*)_0$.

Moreover $u_0 \geqq 0$, $u_1 \geqq 0$ for $f \geqq 0$. □

This result for $f \geqq 0$ was also pointed out by Brezis-Nirenberg in [B.N.1]. Their approach however uses in an essential way the fact that f does not change sign. It relies on a result of Crandall-Rabinowitz [C.R.] and techniques developed in [B.N.2].

Furthermore for $f \geqq 0$ it is known that (1.2) cannot admit positive solution when $\|f\|_{\mathrm{H}^{-1}}$ is too large (*see* [C.R.], [M.] and [Z]). So our approach necessarily breaks down when $\|f\|_{\mathrm{H}^{-1}}$ is large. In fact we suspect that assumptions $(*)_0$ and $(*)$ on f are not only sufficient but also *necessary* to guarantee the statements of Theorems 1 and 2.

By a result of Brezis-Kato [B-K] we know that Theorem 3 gives *classical* solutions if f is sufficiently regular and $\partial\Omega$ is smooth; and for $f \geqq 0$, via the strong maximum principle, such solutions are *strictly* positive in Ω.

Obviously an equivalent of Theorem 3 holds for the *subcritical* case where one replaces the power $p = \dfrac{2\mathrm{N}}{\mathrm{N}-2}$ in (1.2) by $q \in \left(2, \dfrac{2\mathrm{N}}{\mathrm{N}-2}\right)$. In such a case more standard compactness arguments apply, and the proof can be consistently simplified. The details are left to the interested reader. Finally going back to the functional I, if f satisfies $(*)$ then Theorem 1 suggests a mountain-pass procedure; which will be carried out as follows.

Take:

$$u_\varepsilon(x) = \frac{\varepsilon^{(\mathrm{N}-2)/2}}{(\varepsilon^2 + |x|^2)^{(\mathrm{N}-2)/2}} \qquad \varepsilon > 0, \quad x \in \mathbb{R}^{\mathrm{N}} \tag{1.6}$$

be an extremal function for the Sobolev inequality in $\mathbb{R}^{\mathrm{N}}$.

For $a \in \Omega$ let $u_{\varepsilon, a}(x) = u_\varepsilon(x-a)$, and

$$\xi_a \in \mathrm{C}_0^\infty(\Omega) \qquad \text{with} \quad \xi_a \geqq 0 \quad \text{and} \quad \xi_a = 1 \text{ near } a. \tag{1.7}$$

Set

$$\mathcal{F}=\left\{\begin{matrix} h:[0,1]\rightarrow \mathrm{H} \text{ continuous, } h(0)=u_0 \\ h(1)=\mathrm{R}_0\,\xi_a\,u_{\varepsilon,a}\end{matrix}\right\}$$

$\mathrm{R}_0>0$ fixed.

We have:

THEOREM 4. — For a suitable choice of $\mathrm{R}_0>0$, $a\in\Omega$ and $\varepsilon>0$ the value

$$c=\inf_{h\in\mathcal{F}}\ \max_{t\in[0,1]}\mathrm{I}(h,(t))$$

defines a critical value for I, and $c\geqq c_1$. □

It is not clear whether or not $c=c_1$. So no additional multiplicity can be claimed for (1.2). However, in case $c=c_1$ then it is possible to claim a critical point of mountain-pass type (*cf.* [H]) for I in Λ^-. This follows by a refined version of the mountain-pass lemma (*see* [A-R]) obtained by Ghoussoub-Preiss and the fact that Λ^- cannot contain local minima for I (*see* [G.P., theorem (ter) part *a*]).

The referee has brought to our attention a paper of O. Rey (*See* [R.]) where, by a different approach, a result similar to that of Theorem 3 is established when $f\neq 0$, $f\geqq 0$ and $\|f\|_{\mathrm{H}^{-1}}$ is sufficiently small.

2. THE PROOF OF THEOREM 1

To obtain the proof of Theorem 1 several preliminary results are in order.

We start with a lemma which clarifies the purpose of assumption $(*)$.

LEMMA 2.1. — *Let $f\neq 0$ satisfy $(*)$. For every $u\in\mathrm{H}$, $u\neq 0$ there exists a unique $t^+=t^+(u)>0$ such that $t^+u\in\Lambda^-$. In particular:*

$$t^+>\left[\frac{\|\nabla u\|_2^2}{(p-1)\|u\|_p^p}\right]^{1/(p-2)}:=t_{\max}$$

and $\mathrm{I}(t^+u)=\max_{t\geqq t_{\max}}\mathrm{I}(tu)$

Moreover, if $\int_\Omega fu>0$, then there exists a *unique* $t^-=t^-(u)>0$ such that $t^-u\in\Lambda^+$.

In particular,

$$t^-<\left[\frac{\|\nabla u\|_2^2}{(p-1)\|u\|_p^p}\right]^{1/(p-2)}$$

and $\mathrm{I}(t^-u)\leqq\mathrm{I}(tu)$, $\forall\, t\in[0,t^+]$.

Proof. – Set $\varphi(t)=t\,\|\nabla u\|_2^2-t^{p-1}\|u\|_p^p$. Easy computations show that φ is concave and achieves its maximum at

$$t_{\max}=\left[\frac{\|\nabla u\|_2^2}{(p-1)\|u\|_p^p}\right]^{1/(p-2)}.$$

Also

$$\varphi(t_{\max})=\left[\frac{1}{p-1}\right]^{(p-1)/(p-2)}(p-2)\left[\frac{\|\nabla u\|_2^{2(p-1)}}{\|u\|_p^p}\right]^{1/(p-2)},$$

that is

$$\varphi(t_{\max})=c_{\mathrm{N}}\frac{\|\nabla u\|_2^{(\mathrm{N}+2)/2}}{\|u\|_p^{\mathrm{N}/2}}.$$

Therefore if $\int_\Omega fu\leqq 0$ then there exists a *unique* $t^+>t_{\max}$ such that: $\varphi(t^+)=\int_\Omega fu$ and $\varphi'(t^+)<0$. Equivalently $t^+u\in\Lambda^-$ and $\mathrm{I}(t^+u)\geqq\mathrm{I}(tu)\ \forall\, t\geqq t_{\max}$.

In case $\int_\Omega fu>0$, by assumption (∗) we have that necessarily

$$\int_\Omega fu<c_{\mathrm{N}}\frac{\|\nabla u\|_2^{(\mathrm{N}+2)/2}}{\|u\|_p^{\mathrm{N}/2}}=\varphi(t_{\max}).$$

Consequently, in this case, we have unique $0<t^-<t_{\max}<t^+$ such that

$$\varphi(t^+)=\int_\Omega fu=\varphi(t^-)$$

and

$$\varphi'(t^-)>0>\varphi'(t^+).$$

Equivalently $t^+u\in\Lambda^-$ and $t^-u\in\Lambda^+$.

Also $\mathrm{I}(t^+u)\geqq\mathrm{I}(tu)$, $\forall\, t\geqq t^-$ and $\mathrm{I}(t^-u)\leqq\mathrm{I}(tu)$, $\forall\, t\in[0,\,t^+]$.

LEMMA 2.2. – *For* $f\neq 0$

$$\inf_{\|u\|_p=1}\left(c_{\mathrm{N}}\|\nabla u\|^{(\mathrm{N}+2)/2}-\int_\Omega fu\right):=\mu_0 \tag{2.1}$$

is achieved. In particular if f *satisfies* (∗), *then* $\mu_0>0$.

The proof of Lemma 2.2 is technical and a straightforward adaptation of that given in [B.N.1] for an analogous minimization problem.

It will be given in the appendix for the reader's convenience.

Next, for $u \neq 0$ set

$$\psi(u) = c_N \frac{\|\nabla u\|_2^{(N+2)/2}}{\|u\|_p^{N/2}} - \int_\Omega fu.$$

Since for $t > 0$, $\|u\|_p = 1$ we have:

$$\psi(tu) = t\left[c_N \|\nabla u\|_2^{(N+2)/2} - \int_\Omega fu\right];$$

given $\gamma > 0$, from Lemma 2.2 we derive that

$$\inf_{\|u\| \geqq \gamma} \psi(u) \geqq \gamma \mu_0. \tag{2.2}$$

In particular if f satisfies $(*)$ then the infinum (2.2) is bounded away from zero.
This remark is crucial for the following:

LEMMA 2.3. – *Let f satisfy $(*)$. For every $u \in \Lambda$, $u \neq 0$ we have*

$$\|\nabla u\|_2^2 - (p-1)\|u\|_p^p \neq 0$$

(i. e. $\Lambda_0 = \{0\}$).

Proof. – Although the result also holds for $f = 0$, we shall only be concerned with the case $f \neq 0$.
Arguing by contradiction assume that for some $u \in \Lambda$, $u \neq 0$ we have

$$\|\nabla u\|_2^2 - (p-1)\|u\|_p^p = 0 \tag{2.3}$$

Thus

$$0 = \|\nabla u\|_2^2 - \|u\|_p^p - \int_\Omega fu = (p-2)\|u\|_p^p - \int_\Omega fu. \tag{2.4}$$

Condition (2.3) implies

$$\|u\|_p \geqq \left(\frac{S}{p-1}\right)^{1/(p-2)} := \gamma,$$

and from (2.2) and (2.4) we obtain:

$$0<\mu_0\gamma\leqq\psi(u)=\left[\frac{1}{p-1}\right]^{(p-1)/(p-2)}(p-2)\left[\frac{\|\nabla u\|_2^{2(p-1)}}{\|u\|_p^p}\right]^{1/(p-2)}-\int_\Omega fu$$
$$=(p-2)\left(\left[\frac{1}{p-1}\right]^{(p-1)/(p-2)}\left[\frac{\|\nabla u\|_2^{2(p-1)}}{\|u\|_p^p}\right]^{1/(p-2)}-\|u\|_p^p\right)$$
$$=(p-2)\|u\|_p^p\left(\left[\frac{\|\nabla u\|_2^2}{(p-1)\|u\|_p^p}\right]^{(p-1)/(p-2)}-1\right)=0$$

which yields to a contradiction. □

As a consequence of Lemma 2.3 we have:

LEMMA 2.4. – *Let $f\neq 0$ satisfy* (*). *Given $u\in\Lambda$, $u\neq 0$ there exist $\varepsilon>0$ and a differentiable function $t=t(w)>0$, $w\in H\,\|w\|<\varepsilon$ satisfying the following:*

$$t(0)=1,\qquad t(w)(u-w)\in\Lambda,\quad \text{for } \|w\|<\varepsilon,$$

and

$$\langle t'(0), w\rangle=\frac{2\int_\Omega \nabla u.\nabla w-p\int_\Omega |u|^{p-2}uw\int_\Omega fw}{\|\nabla u\|_2^2-(p-1)\|u\|_p^p}. \tag{2.5}$$

Proof. – Define $F:\mathbb{R}\times H\to\mathbb{R}$ as follows:

$$F(t,w)=t\|\nabla(u-w)\|_2^2-t^{p-1}\|u-w\|_p^p-\int_\Omega f(u-w).$$

Since $F(1,0)=0$ and $F_t(1,0)=\|\nabla u\|_2^2-(p-1)\|u\|_p^p\neq 0$ (by Lemma 2.3), we can apply the implicit function theorem at the point $(1,0)$ and get the result. □

We are now ready to give:

The Proof of Theorem 1

We start by showing that I is bounded from below in Λ. Indeed for $u\in\Lambda$ we have:

$$\int_\Omega |\nabla u|^2-\int_\Omega |u|^p-\int_\Omega fu=0.$$

Thus:

$$I(u)=\frac{1}{2}\int_\Omega |\nabla u|^2-\frac{1}{p}\int_\Omega |u|^p-\int_\Omega fu=\frac{1}{N}\int_\Omega |\nabla u|^2-\left(1-\frac{1}{p}\right)\int_\Omega fu$$
$$\geqq\frac{1}{N}\|\nabla u\|_2^2-\frac{N+2}{2N}\|f\|_{H^{-1}}\|\nabla u\|_2\geqq-\frac{1}{16N}[(N+2)\|f\|_{H^{-1}}]^2.$$

In particular

$$c_0 \geqq -\frac{1}{16\mathrm{N}}[(\mathrm{N}+2)\|f\|_{\mathrm{H}^{-1}}]^2. \tag{2.6}$$

We first obtain our result for f satisfying $(*)$. The more general situation where f satisfies $(*)_0$ will be subsequently derived by a limiting argument.

So from now on we assume that f satisfy $(*)$.

In order to obtain an upper bound for c_0, let $v \in \mathrm{H}$ be the unique solutions for $-\Delta u = f$. So for $f \neq 0$

$$\int_\Omega fv = \|\nabla v\|_2^2 > 0.$$

Set $t_0 = t^-(v) > 0$ as defined by Lemma 2.1.

Hence $t_0 v \in \Lambda^+$ and consequently:

$$\begin{aligned}\mathrm{I}(t_0 v) &= \frac{t_0^2}{2}\|\nabla v\|_2^2 - \frac{t_0^p}{p}\|v\|_p^p - t_0\|\nabla v\|_2^2 \\ &= -\frac{t_0^2}{2}\|\nabla v\|_2^2 + \frac{p-1}{p} t_0^p \|v\|_p^p < -\frac{t_0^2}{\mathrm{N}}\|\nabla v\|_2^2 = -\frac{t_0^2}{\mathrm{N}}\|f\|_{\mathrm{H}^{-1}}^2\end{aligned}$$

This yields,

$$c_0 < -\frac{t_0^2}{\mathrm{N}}\|f\|_{\mathrm{H}^{-1}}^2 < 0. \tag{2.7}$$

Clearly Ekeland's variational principle (*see* [A.E.], Corollary 5.3.2) applies to the minimization problem (1.3). It gives a minimizing sequence $\{u_n\} \subset \Lambda$ with the following properties:

(i) $\mathrm{I}(u_n) < c_0 + \frac{1}{n}$.

(ii) $\mathrm{I}(w) \geqq \mathrm{I}(u_n) - \frac{1}{n}\|\nabla(w - u_n)\|_2, \ \forall w \in \Lambda$.

By taking n large, from (2.7) we have:

$$\mathrm{I}(u_n) = \frac{1}{\mathrm{N}}\int_\Omega |\nabla u_n|^2 - \frac{\mathrm{N}+2}{2\mathrm{N}}\int_\Omega f u_n < c_0 + \frac{1}{n} < -\frac{t_0^2}{\mathrm{N}}\|f\|_{\mathrm{H}^{-1}}^2 \tag{2.8}$$

This implies

$$\int_\Omega f u_n \geqq \frac{2}{\mathrm{N}+2} t_0^2 \|f\|_{\mathrm{H}^{-1}}^2 > 0. \tag{2.9}$$

Consequently $u_n \neq 0$, and putting together (2.8) and (2.9) we derive:

$$\frac{2t_0^2}{\mathrm{N}+2}\|f\|_{\mathrm{H}^{-1}} \leqq \|\nabla u_n\|_2 \leqq \frac{\mathrm{N}+2}{2}\|f\|_{\mathrm{H}^{-1}}. \tag{2.10}$$

Our goal is to obtain $\| I'(u_n) \| \to 0$ as $n \to +\infty$.

Hence let us assume $\| I'(u_n) \| > 0$ for n large (otherwise we are done).

Applying Lemma 2.4 with $u = u_n$ and $w = \delta \dfrac{I'(u_n)}{\| I'(u_n) \|}$ $\delta > 0$ small, we find, $t_n(\delta) := t\left[\delta \dfrac{I'(u_n)}{\| I'(u_n) \|}\right]$ such that

$$w_\delta = t_n(\delta)\left[u_n - \delta \frac{I'(u_n)}{\| I'(u_n) \|}\right] \in \Lambda.$$

From condition (ii) we have:

$$\frac{1}{n} \| \nabla (w_\delta - u_n) \|_2 \geqq I(u_n) - I(w_\delta) = (1 - t_n(\delta)) \langle I'(w_\delta), u_n \rangle$$
$$+ \delta\, t_n(\delta) \left\langle I'(w_\delta), \frac{I'(u_n)}{\| I'(u_n) \|} \right\rangle + o(\delta).$$

Dividing by $\delta > 0$ and passing to the limit as $\delta \to 0$ we derive:

$$\frac{1}{n}(1 + |t'_n(0)|\, \| \nabla u_n \|_2) \geqq - t'_n(0) \langle I'(u_n), u_n \rangle + \| I'(u_n) \| = \| I'(u_n) \|$$

where we have set $t'_n(0) = \left\langle t'(0), \dfrac{I'(u_n)}{\| I'(u_n) \|} \right\rangle$.

Thus from (2.10) we conclude:

$$\| I'(u_n) \| \leqq \frac{C}{n}(1 + |t'_n(0)|)$$

for a suitable positive constant C.

We are done once we show that $|t'_n(0)|$ is bounded uniformly on n.

From (2.5) and the estimate (2.10) we get:

$$|t'_n(0)) \leqq \frac{C_1}{| \| \nabla u_n \|_2^2 - (p-1) \| u_n \|_p^p |}$$

$C_1 > 0$ suitable constant.

Hence we need to show that $| \| \nabla u_n \|_2^2 - (p-1) \| u_n \|_p^p |$ is bounded away from zero.

Arguing by contradiction, assume that for a subsequence, which we still call u_n, we have:

$$\| \nabla u_n \|_2^2 - (p-1) \| u_n \|_p^p = o(1). \tag{2.11}$$

From the estimate (2.10) and (2.11) we derive:

$$\| u_n \|_p \geqq \gamma \qquad (\gamma > 0 \text{ suitable constant})$$

and

$$\left[\frac{\|\nabla u_n\|_2^2}{p-1}\right]^{(p-1)/(p-2)} - [\|u_n\|_p^p]^{(p-1)/(p-2)} = o(1).$$

In addition (2.11), and the fact that $u_n \in \Lambda$ also give:

$$\int_\Omega f u_n = (p-2)\|u_n\|_p^p + o(1).$$

This, together with (2.2) implies:

$$\begin{aligned} 0<\mu_0\gamma^{(N+2)/2} &\leqq \|u_n\|_p^{p/(p-2)}\psi(u_n) \\ &= (p-2)\left[\left[\frac{\|\nabla u_n\|_2^2}{p-1}\right]^{(p-1)/(p-2)} - [\|u_n\|_p^p]^{(p-1)/(p-2)}\right] = o(1). \end{aligned}$$

which is clearly impossible.

In conclusion:

$$\|I'(u_n)\| \to 0 \quad \text{as } n \to +\infty. \tag{2.12}$$

Let $u_0 \in H$ be the weak limit in $H_0^1(\Omega)$ of (a subsequence of) u_n.
From (2.9) we derive that:

$$\int_\Omega f u_0 > 0$$

and from (2.12) that

$$\langle I'(u_0), w\rangle = 0, \qquad \forall w \in H,$$

i.e. u_0 is a weak solution for (1.2).

In particular, $u_0 \in \Lambda$.

Therefore:

$$c_0 \leqq I(u_0) = \frac{1}{N}\|\nabla u_0\|_2^2 - \int_\Omega f u_0 \leqq \lim_{n \to +\infty} I(u_n) = c_0.$$

Consequently $u_n \to u_0$ strongly in H and $I(u_0) = c_0 = \inf_\Lambda I$. Also from Lemma 2.1 and (2.12) follows that necessarily $u_0 \in \Lambda^+$.

To conclude that u_0 is a local minimum for I, notice that for every $u \in H$ with $\int_\Omega f u > 0$ we have:

$$I(su) \geqq I(t^- u)$$

$$\text{for every } 0 < s < \left[\frac{\|\nabla u\|_2^2}{(p-1)\|u\|_p^p}\right]^{1/(p-2)} \tag{2.13}$$

(*see* Lemma 2.1).

In particular for $u=u_0\in\Lambda^+$ we have:

$$t^- = 1 < \left[\frac{\|\nabla u_0\|_2^2}{(p-1)\|u\|_p^p}\right]^{1/(p-2)}. \tag{2.14}$$

Let $\varepsilon>0$ sufficiently small to have:

$$1 < \frac{\|\nabla (u_0-w)\|_2^2}{(p-1)\|u_0-w\|_p^p}$$

for $\|w\|<\varepsilon$.

From Lemma 2.4, let $t(w)>0$ satisfy $t(w)(u_0-w)\in\Lambda$ for every $\|w\|<\varepsilon$.

Since $t(w)\to 1$ as $\|w\|\to 0$, we can always assume that

$$t(w) < \left[\frac{\|\nabla (u_0-w)\|_2^2}{(p-1)\|u_0-w\|_p^p}\right]^{1/(p-2)}$$

for every $w:\|w\|<\varepsilon$.

Namely, $t(w)(u_0-w)\in\Lambda^+$ and for $0<s<\left[\frac{\|\nabla (u_0-w)\|_2^2}{(p-1)\|u_0-w\|_p^p}\right]^{1/(p-2)}$ we have,

$$\mathrm{I}(s(u_0-w)) \geqq \mathrm{I}(t(w)(u_0-w)) \geqq \mathrm{I}(u_0).$$

From (2.14) we can take $s=1$ and conclude:

$$\mathrm{I}(u_0-w) \geqq \mathrm{I}(w), \qquad \forall w\in\mathrm{H},\quad \|w\|<\varepsilon.$$

Furthermore if $f\geqq 0$, take, $t_0=t^-(|u_0|)>0$ with $t_0|u_0|\in\Lambda^+$.

Necessarily $t_0\geqq 1$, and

$$\mathrm{I}(t_0|u_0|) \leqq \mathrm{I}(|u_0|) \leqq \mathrm{I}(u_0).$$

So we can always take $u_0\geqq 0$.

To obtain the proof when f satisfies $(*)_0$ we shall apply an approximation argument. To this purpose, notice that if f satisfies $(*)_0$ then $f_\varepsilon=(1-\varepsilon)f$ satisfies $(*)$ $\forall\varepsilon\in(0,1)$.

Set

$$\mathrm{I}_\varepsilon(u) = \frac{1}{2}\int_\Omega |\nabla u|^2 - \frac{1}{p}\int_\Omega |u|^p + (1-\varepsilon)\int_\Omega fu, \qquad u\in\mathrm{H}.$$

Let $u_\varepsilon\in\Lambda_\varepsilon^+=\{u\in\mathrm{H}: \langle \mathrm{I}'_\varepsilon(u), u\rangle = 0,\ \|\nabla u\|_2^2-(p-1)\|u\|_p^p>0\}$ satisfy:

$$\mathrm{I}_\varepsilon(u_\varepsilon) = \inf_{\Lambda_\varepsilon} \mathrm{I}_\varepsilon := c_\varepsilon$$

and

$$\langle \mathrm{I}'_\varepsilon(u_\varepsilon), w\rangle = 0, \qquad \forall w\in\mathrm{H}. \tag{2.15}$$

Clearly $\|\nabla u_\varepsilon\|_2 \leqq \mathrm{C}_2$, for $0<\varepsilon<1$ and $\mathrm{C}_2>0$ a suitable constant.

Let $u \in \Lambda^+$, necessarily $\int_\Omega fu > 0$ and consequently

$$(1-\varepsilon)\int_\Omega fu > 0, \qquad 0<\varepsilon<1.$$

From Lemma 2.1 applied with $f=f_\varepsilon$ we find:

$$0 < t_\varepsilon^- < \left[\frac{\|\nabla u\|_2^2}{(p-1)\|u\|_p^p}\right]^{1/(p-2)}$$

with $t_\varepsilon^- u \in \Lambda_\varepsilon^+$.

Since $1 < \dfrac{\|\nabla u\|_2^2}{(p-1)\|u\|_p^p}$, from (2.13) it follows that

$$I_\varepsilon(t_\varepsilon^- u) \leqq I_\varepsilon(u)$$

and consequently:

$$c_\varepsilon \leqq I_\varepsilon(t_\varepsilon u) \leqq I_\varepsilon(u) \leqq I(u) + \varepsilon \|f\|_{H^{-1}} \|\nabla u\|_2 \leqq I(u) + \varepsilon C_3$$

(with $C_3 > 0$ a suitable constant).

Estimate (2.6) with $f=f_\varepsilon$ and the above inequality imply:

$$-\frac{1}{16N}[(N+2)\|f\|_{H^{-1}}]^2 \leqq -\frac{1}{16N}[(N+2)\|f_\varepsilon\|_{H^{-1}}]^2 \leqq c_\varepsilon \leqq c_0 + \varepsilon C_3.$$

Let $\varepsilon_n \to 0$, $n \to +\infty$ and $u_0 \in H$ satisfy:

(*a*) $c_{\varepsilon_n} \to \bar{c} \leqq c_0$, $n \to +\infty$

(*b*) $u_{\varepsilon_n} \to u_0$, $n \to +\infty$ weakly in H.

From (2.15) it follows $\langle I'(u_0), w\rangle = 0$, $\forall w \in H$ (*i. e.* u_0 is a critical point for I) and $I(u_0) \leqq c_0$.

In particular $u_0 \in \Lambda$ and necessarily $I(u_0) = c_0$, (*i. e.* $u_{\varepsilon_n} \to u_0$ strongly in H).

This completes the proof. □

3. THE PROOF OF THEOREMS 2 AND 4

The functional I involves the limiting Sobolev exponent $p = \dfrac{2N}{N-2}$. This compromises its compactness properties, and a possible failure of the P.S. condition is to be expected.

Our first task is to locate the levels free from this noncompactness effect.

We refer to [B] and [S] for a survey on related problems where such an approach has been successfully used.

In this direction we have:

PROPOSITION 3.1. – *Every sequence* $\{u_n\} \subset \mathrm{H}$ *satisfying*:

(*a*) $\mathrm{I}(u_n) \to c$ *with* $c < c_0 + \frac{1}{\mathrm{N}} \mathrm{S}^{\mathrm{N}/2}$

[c_0 *as defined in* (1.3)].

(*b*) $\|\mathrm{I}'(u_n)\| \to 0$

as a convergent subsequence.

Namely the (P.S) condition holds for all level $c < c_0 + \frac{1}{\mathrm{N}} \mathrm{S}^{\mathrm{N}/2}$.

Proof. – It is not difficult to see that (*a*) and (*b*) imply that $\|\nabla u_n\|_2$ is uniformly bounded.

Hence for a subsequence of u_n (which we still call u_n), we can find a $w_0 \in \mathrm{H}$ such that

$$u_n \to w_0 \text{ weakly in H.}$$

Consequently from (*b*) we obtain:

$$\langle \mathrm{I}'(w_0), w \rangle = 0, \qquad \forall w \in \mathrm{H}. \tag{3.1}$$

That is w_0 is a solution in $\mathrm{H}_0^1(\Omega)$ for (1.2). In particular $w_0 \neq 0$, $w_0 \in \Lambda$ and $\mathrm{I}(w_0) \geqq c_0$.

Write $u_n = w_0 + v_n$ with $v_n \to 0$ weakly in H.

By a Lemma of Brezis-Lieb [B.L.] we have:

$$\|u_n\|_p^p = \|w_0 + v_n\|_p^p = \|w_0\|_p^p + \|v_n\|_p^p + o(1).$$

Hence, for n large, we conclude:

$$\begin{aligned} c_0 + \frac{1}{\mathrm{N}} \mathrm{S}^{\mathrm{N}/2} > \mathrm{I}(w_0 + v_n) = I(w_0) + \frac{1}{2} \|\nabla v_n\|_2^2 - \frac{1}{p} \|v_n\|_p^p + o(1) \\ \geqq c_0 + \frac{1}{2} \|\nabla v_n\|_2^2 - \frac{1}{p} \|v_n\|_p^p + o(1). \end{aligned}$$

which gives:

$$\frac{1}{2} \|\nabla v_n\|_2^2 - \frac{1}{p} \|v_n\|_p^p < \frac{1}{\mathrm{N}} \mathrm{S}^{\mathrm{N}/2} + o(1). \tag{3.2}$$

Also from (*b*) follows:

$$\begin{aligned} o(1) = \langle \mathrm{I}'(u_n), u_n \rangle = \|\nabla w_0\|^2 - \|w_0\|_p^p - \int_\Omega f w_0 + \|\nabla v_n\|_2^2 - \|v_n\|_p^p + o(1) \\ = \langle \mathrm{I}'(w_0), w_0 \rangle + \|\nabla v_n\|_2^2 - \|v_n\|_p^p + o(1): \end{aligned}$$

and taking into account (3.1) we obtain:

$$\|\nabla v_n\|_2^2 - \|v_n\|_p^p = o(1). \tag{3.3}$$

We claim that conditions (3.2) and (3.3) can hold simultaneously only if $\{v_n\}$ admits a subsequence, $\{v_{n_k}\}$ say, which converges strongly to zero, *i.e.* $\|v_{n_k}\| \to 0$, $k \to +\infty$.

Arguing by contradiction assume that $\|v_n\|$ is bounded away from zero. That is for some constant $c_4>0$ we have $\|v_n\| \geqq c_4$, $\forall n \in \mathbb{N}$.

From (3.3) then it follows:

$$\|v_n\|_p^{p-2} \geqq S + o(1),$$

and consequently

$$\|v_n\|_p^p \geqq S^{N/2} + o(1).$$

This yields a contradiction since from (3.2) and (3.3) we have:

$$\frac{1}{N} S^{N/2} \leqq \frac{1}{N}\|v_n\|_p^p + o(1) = \frac{1}{2}\|\nabla v_n\|_2^2 - \frac{1}{p}\|v_n\|_p^p + o(1) < \frac{1}{N} S^{N/2}$$

for n large.

In conclusion, $u_{n_k} \to w_0$ strongly. □

At this point it would not be difficult to derive Theorem 2, if we had the inequality:

$$\inf_{\Lambda^-} I = c_1 < c_0 + \frac{1}{N} S^{N/2}. \tag{3.4}$$

However it appears difficult to derive (3.4) directly.

We shall obtain it by comparison with a mountain-pass value.

To this end, recall that $u_0 \neq 0$. Following [B.N.1] we set $\Sigma \subset \Omega$ to be a set of positive measure such that $u_0>0$ on Σ (replace u_0 with $-u_0$ and f with $-f$ if necessary).

$$\text{Set } U_{\varepsilon, a}(x) = \xi_a(x)\, u_{\varepsilon, a}(x), \qquad x \in \mathbb{R}^N;$$

[$u_{\varepsilon, a}$ and ξ_a defined in (1.6) and (1.7)].

LEMMA 3.1. – *For every* $R>0$ *and a.e.* $a \in \Sigma$, *there exists* $\varepsilon_0 = \varepsilon_0(R, a) > 0$ *such that*:

$$I(u_0 + R U_{\varepsilon, a}) < c_0 + \frac{1}{N} S^{N/2}$$

for every $0 < \varepsilon < \varepsilon_0$.

Proof. – We have:

$$I(u_0 + R U_{\varepsilon, a}) = \int_\Omega \frac{|\nabla u_0|^2}{2} + R\int_\Omega \nabla u_0 \nabla U_{\varepsilon, a} + \frac{R^2}{2}\int_\Omega |\nabla U_{\varepsilon, a}|^2 - \frac{1}{p}\int_\Omega |u_0 + R U_{\varepsilon, a}|^p - \int_\Omega f u_0 - R\int_\Omega f U_{\varepsilon, a}. \tag{3.5}$$

A careful estimate obtained by Brezis-Nirenberg (*see* formulae (17) and (22) in [B.N.1]) shows that:

$$\|u_0+\mathrm{R}\mathrm{U}_{\varepsilon, a}\|_p^p = \|u_0\|_p^p + \mathrm{R}^p\|\mathrm{U}_{\varepsilon, a}\|_p^p + p\mathrm{R}\int_\Omega |u_0|^{p-2}u_0\mathrm{U}_{\varepsilon, a}$$
$$+p\mathrm{R}^{p-1}\int_\Omega \mathrm{U}_{\varepsilon, a}^{p-1}u_0 + o[\varepsilon^{(\mathrm{N}-2)/2}] \quad \text{for a.e. } a\in\Sigma.$$

Also from [B.N.2] we have:

$$\|\nabla \mathrm{U}_{\varepsilon, a}\|_2^2 = \mathrm{B} + O(\varepsilon^{\mathrm{N}-2}) \qquad \text{and} \qquad \|\mathrm{U}_{\varepsilon, a}\|_p^p = \mathrm{A} + O(\varepsilon^{\mathrm{N}})$$

where

$$\mathrm{B} = \int_{\mathbb{R}^\mathrm{N}} |\nabla u_1(x)|^2\, dx, \ \mathrm{A} = \int_{\mathbb{R}^\mathrm{N}} \frac{dx}{(1+|x|^2)^\mathrm{N}}$$

and

$$\mathrm{S} = \frac{\mathrm{B}}{\mathrm{A}^{2/p}}. \tag{3.6}$$

Substituting in (3.5) and using the fact that u_0 satisfies (1.2) we obtain:

$$\mathrm{I}(u_0+\mathrm{R}\mathrm{U}_{\varepsilon, a}) = \frac{1}{2}\int_\Omega |\nabla u_0|^2 + \mathrm{R}\int_\Omega \nabla u_0 . \nabla \mathrm{U}_{\varepsilon, a} + \frac{\mathrm{R}^2}{2}\mathrm{B} - \frac{1}{p}\int_\Omega |u_0|^p - \frac{\mathrm{R}^p}{p}\mathrm{A}$$
$$-\mathrm{R}\int_\Omega |u_0|u_0^{p-2}\mathrm{U}_{\varepsilon, a} - \mathrm{R}^{p-1}\int_\Omega \mathrm{U}_{\varepsilon, a}^{p-1}u_0 - \int_\Omega f u_0 - \mathrm{R}\int_\Omega f\mathrm{U}_{\varepsilon, a} + o[\varepsilon^{(\mathrm{N}-2)/2}]$$
$$= \mathrm{I}(u_0) + \frac{\mathrm{R}^2}{2}\mathrm{B} - \frac{\mathrm{R}^p}{p}\mathrm{A} - \mathrm{R}^{p-1}\int_\Omega \mathrm{U}_{\varepsilon, a}^{p-1}u_0 + o[\varepsilon^{(\mathrm{N}-2)/2}]$$

for a.e. $a\in\Sigma$.

Set $u_0=0$ outside Ω, it follows:

$$\int_\Omega \mathrm{U}_{\varepsilon, a}^{p-1}u_0 = \int_{\mathbb{R}^\mathrm{N}} u_0(x)\xi_a(x)\frac{\varepsilon^{(\mathrm{N}+2)/2}}{(\varepsilon^2+|x-a|^2)^{(\mathrm{N}+2)/2}}dx$$
$$= \varepsilon^{(\mathrm{N}-2)/2}\int_{\mathbb{R}^\mathrm{N}} u_0(x)\xi_a(x)\frac{1}{\varepsilon^\mathrm{N}}\psi_1\left(\frac{x}{\varepsilon}\right)dx,$$

where $\psi_1(x) = \dfrac{1}{(1+|x|^2)^{(\mathrm{N}+2)/2}} \in \mathrm{L}^1(\mathbb{R}^\mathrm{N})$.

Therefore, setting $\mathrm{D} = \displaystyle\int_{\mathbb{R}^\mathrm{N}} \frac{dx}{(1+|x|^2)^{(\mathrm{N}+2)/2}}$ we derive:

$$\int_{\mathbb{R}^\mathrm{N}} u_0(x)\xi_a(x)\frac{1}{\varepsilon^\mathrm{N}}\psi_1\left(\frac{x}{\varepsilon}\right)dx \to u_0(a)\mathrm{D}$$

for a.e. $a\in\Sigma$ (*see* [F]).

In other words,

$$\int_\Omega U_{\varepsilon,a}^{p-1}(x)\,u_0(x)\,dx=\varepsilon^{(N-2)/2}\,u_0(a)\,D+o\,(\varepsilon^{(N-2)/2}).$$

Consequently:

$$I(u_0+RU_{\varepsilon,a})=c_0+\frac{R^2}{2}B-\frac{R^p}{p}A-R^{p-1}u_0(a)\,D\,\varepsilon^{(N-2)/2}+o\,[\varepsilon^{(N-2)/2}].$$

Define:

$$q(s)=\frac{s^2}{2}B-\frac{s^p}{P}A-s^{p-1}u_0(a)\,D\,\varepsilon^{(N-2)/2},\qquad s>0$$

and assume that $q(s)$ achieves its maximum at $s_\varepsilon>0$.

Set

$$S_0=\left(\frac{B}{A}\right)^{1/(p-2)}.$$

Since s_ε satisfies:

$$s_\varepsilon B-s_\varepsilon^{p-1}A=(p-1)\,u_0(a)\,D\,\varepsilon^{(N-2)/2}\,s_\varepsilon^{p-2}\tag{3.7}$$

necessarily $0<s_\varepsilon<S_0$ and $s_\varepsilon\to S_0$ as $\varepsilon\to 0$.

Write $s_\varepsilon=S_0(1-\delta_\varepsilon)$. We study the rate at which $\delta_\varepsilon\to 0$ as $\varepsilon\to 0$.

From (3.7) we obtain:

$$\left(\frac{B^{p-1}}{A}\right)^{1/(p-2)}(1-\delta_\varepsilon-(1-\delta_\varepsilon)^{p-1})=(p-1)\frac{B}{A}(1-\delta_\varepsilon)^{p-2}\,\varepsilon^{(N-2)/2}\,u_0(a)\,D;$$

and expanding for δ_ε we derive:

$$(p-2)\left(\frac{B^{p-1}}{A}\right)^{1/(p-2)}\delta_\varepsilon=(p-1)\frac{B}{A}u_0(a)\,D\,\varepsilon^{(N-2)/2}+o\,(\varepsilon^{(N-2)/2}).$$

This implies:

$$\begin{aligned}I(u_0+RU_{\varepsilon,a})&\leqq c_0+\frac{s_\varepsilon^2}{2}B-\frac{s_\varepsilon^p}{p}B-s_\varepsilon^{p-1}u_0(a)\,D\,\varepsilon^{(N-2)/2}+o\,(\varepsilon^{(N-2)/2})\\&=c_0+\frac{S_0^2}{2}B-\frac{S_0^p}{2}A-S_0^2\,B\,\delta_\varepsilon+S_0^p\,A\,\delta_\varepsilon-S_0^{p-1}u_0(a)\,D\,\varepsilon^{(N-2)/2}+o\,(\varepsilon^{(N-2)/2})\\&=c_0+\frac{1}{N}S^{N/2}-S_0^{p-1}u_0(a)\,D\,\varepsilon^{(N-2)/2}+o\,(\varepsilon^{(N-2)/2}).\end{aligned}$$

Therefore for $\varepsilon_0 = \varepsilon_0(\mathrm{R}, a) > 0$ sufficiently small we conclude

$$\mathrm{I}(u_0 + \mathrm{R}\mathrm{U}_{\varepsilon, a}) < c_0 + \frac{1}{\mathrm{N}} \mathrm{S}^{\mathrm{N}/2} \tag{3.8}$$

$\forall\, 0 < \varepsilon < \varepsilon_0$. $\square$

Our aim is to state a mountain pass principle that produces a value which is below the threshold $c_0 + \frac{1}{\mathrm{N}} \mathrm{S}^{\mathrm{N}/2}$ but also compares with the value $c_1 = \inf_{\Lambda^-} \mathrm{I}$.

To this end observe that under assumption $(*)$, the manifold Λ^- disconnects H in exactly two connected components U_1 and U_2.

To see this, notice that for every $u \in \mathrm{H}$, $\|u\| = \|\nabla u\|_2 = 1$ by Lemma 2.1 we can find a unique $t^+(u) > 0$ such that

$$t^+(u)\, u \in \Lambda^- \qquad \text{and} \qquad \mathrm{I}(t^+(u)\, u) = \max_{t \geqq t_{\max}} \mathrm{I}(tu).$$

The uniqueness of $t^+(u)$ and its extremal property give that $t^+(u)$ is a continuous function of u.

Set

$$\mathrm{U}_1 = \left\{ u = 0 \text{ or } u : \|u\| < t^+\left(\frac{u}{\|u\|}\right) \right\}$$

and

$$\mathrm{U}_2 = \left\{ u : \|u\| > t^+\left(\frac{u}{\|u\|}\right) \right\}.$$

Clearly $\mathrm{H} - \Lambda^- = \mathrm{U}_1 \cup \mathrm{U}_2$ and $\Lambda^+ \subset \mathrm{U}_1$.

In particular $u_0 \in \mathrm{U}_1$.

The Proof of Theorem 4

Easy computations show that, for suitable constant $\mathrm{C}_5 > 0$ we have:

$$0 < t^+(u) < \mathrm{C}_5, \qquad \forall u : \|u\| = 1.$$

Set $\mathrm{R}_0 = \left(\frac{1}{\mathrm{B}} |\mathrm{C}_5^2 - \|u_0\|^2|\right)^{1/2} + 1$ and fix $a \in \Sigma$ such that Lemma 3.2 applies, and the estimate (3.8) holds for all $0 < \varepsilon < \varepsilon_0$.

We claim that

$$w_\varepsilon := u_0 + \mathrm{R}_0\, \xi_a\, u_{\varepsilon, a} \in \mathrm{U}_2 \tag{3.9}$$

for $\varepsilon > 0$ small.

Indeed

$$\|\nabla w_\varepsilon\|_2^2 = \|\nabla(u_0 + R_0 \xi_a U_{\varepsilon, a})\|_2^2$$
$$= \|u_0\|_2^2 + R_0^2 B + o(1) > C_5^2 \geqq \left[t^+\left(\frac{w_\varepsilon}{\|w_\varepsilon\|}\right)\right]^2,$$

for $\varepsilon > 0$ small enough.

For such a choice of R_0 and $a \in \Sigma$, fix $\varepsilon > 0$ such that both (3.8) and (3.9) hold.

Set

$$\mathscr{F} = \left\{ \begin{array}{ll} h : [0, 1] \to H \text{ continuous, } h(0) = u_0 & \\ & h(1) = R_0 \xi_a u_{\varepsilon, a} \end{array} \right\}$$

Clearly $h : [0, 1] \to H$ given by $h(t) = u_0 + t R_0 \xi_a u_{\varepsilon, a}$ belongs to $\mathscr{F}$. So by Lemma 2.3 we conclude:

$$c = \inf_{h \in \mathscr{F}} \max_{t \in [0, 1]} I(h(t)) < c_0 + \frac{1}{N} S^{N/2} \tag{3.10}$$

Also, since the range of any $h \in \mathscr{F}$ intersect Λ^-, we have

$$c \geqq c_1 = \inf_{\Lambda^-} I. \tag{3.11}$$

At this point the conclusion of Theorem 4 follows by Lemma 3.1 and a straightforward application of the mountain-pass lemma (*cf.* [A.R.]). □

The Proof of Theorem 2

Analogously to the proof of Theorem 1, one can show that the Ekeland's variational principle gives a sequence $\{u_n\} \subset \Lambda^-$ satisfying:

$$I'(u_n) \to c_1$$
$$\|I'(u_n)\| \to 0$$

But from (3.10) and (3.11), we have:

$$c_1 < c_0 + \frac{1}{N} S^{N/2}.$$

Thus, by Lemma 3.1, we obtain a subsequence $\{u_{n_k}\}$ of $\{u_n\}$ and $u_1 \in H$ such that:

$$u_{n_k} \to u_1 \text{ strongly in } H.$$

Consequently u_1 is a critical point for I, $u_1 \in \Lambda^-$ (since Λ^- is closed) and $I(u_1) = c_1$.

Finally to see that $f \geqq 0$ yields $u_1 \geqq 0$, let $t^+ > 0$ satisfy

$$t^+ |u_1| \in \Lambda^-.$$

From Lemma 2.1 we conclude:

$$I(u_1)=\max_{t\geqq t_{\max}} I(tu_1)\geqq I(t^+ u_1)\geqq I(t^+ |u_1|).$$

So we can always take $u_1\geqq 0$. □

4. APPENDIX

The Proof of Lemma 2.2

Let $\{u_n\}$ be a minimizing sequence for (2.1) such that for $u_0\in H$ we have $u_n\to u_0$ weakly in H and $u_n\to u_0$ pointwise a.e. in Ω.

In general $\|u_0\|_p\leqq 1$. We are done once we show $\|u_0\|_p=1$.

To obtain this, we shall argue by contradiction and assume

$$\|u_0\|_p<1.$$

Hence write $u_n=u_0+w_n$ where $w_n\to 0$ weakly in H.

We have

$$\mu_0+o(1)=c_n\|\nabla u_n\|^{(N+2)/2}-\int_\Omega fu_n=c_N(\|\nabla u_0\|_2^2+\|\nabla w_n\|_2^2)^{(N+2)/4}-\int_\Omega fu_0+o(1) \quad (4.1)$$

On the other hand,

$$1=\|u_0+w_n\|_p^p=\|u_0\|_p^p+\|w_n\|_p^p+o(1)$$

(*see* [B.L.]), which gives:

$$\|w_n\|_p^2=(1-\|u_0\|_p^p)^{2/p}+o(1).$$

So from (4.1) we conclude:

$$\mu_0+o(1)=c_N(\|\nabla u_0\|_2^2+\|\nabla w_n\|_2^2)^{(N+2)/4}-\int_\Omega fu_0$$
$$\geqq c_N[\|\nabla u_0\|_2^2+S(1-\|u_0\|_p^p)^{2/p}+o(1)]^{(N+2)/4}-\int_\Omega fu_0,$$

That is,

$$c_N[\|\nabla u_0\|_2^2+S(1-\|u_0\|_p^p)^{2/p}]^{(N+2)/4}-\int_\Omega fu_0\leqq\mu_0. \quad (4.2)$$

Following [B.N.1] for every $u\in H$, $\|u\|_p<1$ and $a\in\Omega$ let $c_\varepsilon=c_\varepsilon(a)>0$ satisfy the following:

$$\|u+c_\varepsilon U_{\varepsilon,a}\|_p=1$$

[recall $U_{\varepsilon, a}(x)=\xi_a(x)\, u_{\varepsilon, a}(x)$ with ξ_a and $u_{\varepsilon, a}$ given in (1.6) and (1.7)].

We have:

$$\|\nabla(u+c_\varepsilon U_{\varepsilon, a})\|_2^2=\|\nabla u\|_2^2+c_\varepsilon^2\|\nabla U_{\varepsilon, a}\|_2^2+o(1)$$
$$=\|\nabla u\|_2^2+c_\varepsilon^2 B+o(1) \quad (4.3)$$

and

$$1=\|u+c_\varepsilon U_{\varepsilon, a}\|_p^p=\|u\|_p^p+c_\varepsilon^p,\ \|U_{\varepsilon, a}\|_p^p+o(1)=\|u\|_p^p+c_\varepsilon^p A+o(1)$$

[A, B as given in (3.6)].

Thus

$$c_\varepsilon^2=\frac{1}{A^{2/p}}(1-\|u\|_p^p)^{2/p}+o(1). \quad (4.4)$$

Substituting in (4.3) we obtain:

$$\|\nabla(u+c_\varepsilon U_{\varepsilon, a})\|_2^2=\|\nabla u\|_2^2+\frac{B}{A^{2/p}}(1-\|u\|_p^p)^{2/p}+o(1)$$
$$=\|\nabla u\|_2^2+S(1-\|u\|_p^p)^{2/p}+o(1).$$

This yields:

$$\mu_0\leqq c_N\|\nabla(u+c_\varepsilon U_{\varepsilon, a})\|_2^{(N+2)/2}-\int_\Omega f(u+c_\varepsilon U_{\varepsilon, a})$$
$$=c_N(\|\nabla u\|_2^2+S(1-\|u\|_p^p)^{2/p})^{(N+2)/4}-\int_\Omega fu+o(1),$$

and passing to the limit as $\varepsilon\to 0$, we derive:

$$\mu_0\leqq c_N[\|\nabla u\|_2^2+S(1-\|u\|_p^p)^{2/p}]^{(N+2)/4}-\int_\Omega fu, \qquad \forall u\in H, \quad \|u\|_p<1.$$

Therefore from (4.2) we conclude:

$$c_N[\|\nabla u_0\|_2^2-S(1-\|u_0\|_p^p)^{2/p}]^{(N+2)/4}-\int_\Omega fu=\mu_0 \quad (4.5)$$

and that for every $w\in H$ necessarily:

$$\frac{d}{dt}\left[c_N[\|\nabla(u_0+tw)\|_2^2+S(1-\|u_0+tw\|_p^p)^{2/p}]^{(N+2)/4}-\int_\Omega f(u_0+tw)\right]_{t=0}=0.$$

That is:

$$\frac{N+2}{2}c_N\left[\|\nabla u_0\|_2^2+S(1-\|u_0\|_p^p)^{2/p}\right]^{(N-2)/4}$$
$$\times\left[\int_\Omega \nabla u_0.\nabla w-S(1-\|u_0\|_p^p)^{(2-p)/p}\int_\Omega |u_0|\,u_0^{p-2}\,w\right]$$
$$-\int_\Omega fw=0, \qquad \forall w\in H.$$

So setting $\sigma_0 = \frac{N+2}{2} c_N \left[\| \nabla u_0 \|_2^2 + S(1 - \| u_0 \|_p^p)^{2/p} \right]^{(N-2)/4} > 0$

and

$$\lambda_0 = \frac{S}{(1 - \| u_0 \|_p^p)^{(p-2)/p}}$$

we obtain that u_0 weakly satisfies:

$$-\Delta u_0 = \lambda_0 | u_0 |^{p-2} u_0 + \frac{1}{\sigma_0} f. \tag{4.5}$$

Since $f \neq 0$, in particular, we have that $u_0 \neq 0$.

Hence for a set of positive measure $\Sigma \subset \Omega$ we have:

$$u_0(a) > 0, \qquad \forall a \in \Sigma,$$

(replace u_0 with $-u_0$ and f with $-f$ if necessarily).

Let $a \in \Sigma$ and $c_\varepsilon = c_\varepsilon(a)$ satisfy:

$$\| u_0 + c_\varepsilon U_{\varepsilon, a} \|_p = 1.$$

We will reach a contradiction by showing that

$$I(u_0 + c_\varepsilon U_{\varepsilon, a}) < \mu_0$$

for a suitable choice of $a \in \Sigma$ and $\varepsilon > 0$ small enough.

To this end, let $c_0^p = \frac{1 - \| u_0 \|_p^p}{A}$. From (4.4) it follows that $c_\varepsilon \nearrow c_0$ as $\varepsilon \to 0$. Set $c_\varepsilon = c_0(1 - \delta_\varepsilon)$, $\delta_\varepsilon \to 0$ as $\varepsilon \to 0$. In [B.N.1], Brezis-Nirenberg have obtained a precise rate at which $\delta_\varepsilon \to 0$, by showing that, for a.e. $a \in \Sigma$, one has:

$$\delta_\varepsilon A c_0^p = \varepsilon^{(N-2)/2} \left[c_0 \int_\Omega | u_0(x) | u_0^{p-2}(x) \xi_a(x) \frac{dx}{| x - a |^{N-2}} + c_0^{P-1} u_0(a) D \right] + o(\varepsilon^{(N-2)/2}) \tag{4.7}$$

with

$$D = \int_{\mathbb{R}^N} \frac{dx}{(\varepsilon^2 + | x |^2)^{(N+2)/2}}. \quad (\textit{See} \text{ formula (2.9) in [B.N.1].})$$

Now fix $a \in \Sigma$ for which (4.7) holds and

$$\int_\Omega \frac{| u_0 |^{p-2} u_0 \xi_a}{(\varepsilon^2 + | x - a |^2)^{(N-2)/2}} \to \int_\Omega \frac{| u_0 |^{p-2} u_0 \xi_a}{| x - a |^{N-2}} \quad \text{as } \varepsilon \to 0. \tag{4.8}$$

Using (4.5), (4.7) and the definition of c_0 we obtain:

$$
\begin{aligned}
\mathrm{I}(u_0+c_0\,\mathrm{U}_{\varepsilon,a}) &= c_\mathrm{N}\left[\|\nabla u_0\|_2^2+2\,c_\varepsilon\int_\Omega \nabla u_0\,.\,\nabla \mathrm{U}_{\varepsilon,a}+c_\varepsilon^2\,\|\nabla \mathrm{U}_{\varepsilon,a}\|_2^2\right]^{(\mathrm{N}+2)/4} \\
&\qquad -\int_\Omega f u_0 - c_\varepsilon\int_\Omega f\,\mathrm{U}_{\varepsilon,a} \\
&= c_\mathrm{N}\left[\|\nabla u_0\|_2^2+2\,c_0\int_\Omega \nabla u_0\,.\,\nabla \mathrm{U}_{\varepsilon,a}+c_0^2\,(1-2\,\delta_\varepsilon)\,\mathrm{B}+o\,[\varepsilon^{(\mathrm{N}-2)/2}]\right]^{(\mathrm{N}+2)/4} \\
&\qquad -\int_\Omega f u_0 - c_\varepsilon\int_\Omega f\,\mathrm{U}_{\varepsilon,a} = c_\mathrm{N}\,[\,\|\nabla u_0\|_2^2+c_0^2\,\mathrm{B}]^{(\mathrm{N}+2)/4}-\int_\Omega f u_0 \\
&\qquad +\frac{\mathrm{N}+2}{4}\,c_\mathrm{N}\,[\,\|\nabla u_0\|_2^2+c_0^2\,\mathrm{B}]^{(\mathrm{N}-2)/4}\left[2\,c_0\int_\Omega \nabla u_0\,.\,\nabla \mathrm{U}_{\varepsilon,a}\right. \\
&\qquad \left. -2\,c_0^2\,\delta_\varepsilon\,\mathrm{B}\right]-c_0\int_\Omega f\,\mathrm{U}_{\varepsilon,a} \\
&\qquad +o\,[\varepsilon^{(\mathrm{N}-2)/2}] = \mu_0+c_0\left[\sigma_0\int_\Omega \nabla u_0\,.\,\nabla \mathrm{U}_{\varepsilon,a}\right. \\
&\qquad \left. -\int_\Omega f\,\mathrm{U}_{\varepsilon,a}\right]-\sigma_0\,c_0^2\,\mathrm{B}\,\delta_\varepsilon+o\,[\varepsilon^{(\mathrm{N}-2)/2}].
\end{aligned}
$$

Thus from equation (4.6) we derive:

$$
\mathrm{I}(u_0+c_\varepsilon\,\mathrm{U}_{\varepsilon,a}) = \mu_0+\sigma_0\,\lambda_0\,c_0\int_\Omega |u_0|^{\mathrm{P}-2}\,u_0\,\mathrm{U}_{\varepsilon,a}-\delta_0\,c_0^2\,\mathrm{B}\,\delta_\varepsilon+o\,[\varepsilon^{(\mathrm{N}-2)/2}].
$$

On the other hand from (4.8) we have:

$$
\int_\Omega |u_0|^{p-2}\,u_0\,\mathrm{U}_{\varepsilon,a} = \varepsilon^{(\mathrm{N}-2)/2}\int_\Omega \frac{|u_0(x)|^{p-2}\,u_0(x)}{|x-a|^{\mathrm{N}-2}}\,\xi_a(x)\,dx+o\,[\varepsilon^{(\mathrm{N}-2)/2}].
$$

Therefore:

$$
\begin{aligned}
&\mathrm{I}(u_0+c_\varepsilon\,\mathrm{U}_{\varepsilon,a}) \\
&\quad = \mu_0+\sigma_0\left[\varepsilon^{(\mathrm{N}-2)/2}\,\lambda_0\int_\Omega \frac{|u_0(x)|^{p-2}\,u_0(x)}{|x-a|^{\mathrm{N}-2}}\,\xi_a-c_0^2\,\mathrm{B}\,\delta_\varepsilon\right]+o\,[\varepsilon^{(\mathrm{N}-2)/2}] \\
&\quad = \mu_0+\sigma_0\left[\frac{\mathrm{S}\,\varepsilon^{(\mathrm{N}-2)/2}}{(1-\|u_0\|_p^p)^{(p-2)/2}}\,c_0\int_\Omega \frac{|u_0|^{p-2}\,u_0}{|x-a|^{\mathrm{N}-2}}\,\xi_a-\mathrm{B}\,c_0^2\,\delta_\varepsilon\right]+o\,(\varepsilon^{(\mathrm{N}-2)/2}) \\
&\quad = \mu_0+\sigma_0\left[\frac{\mathrm{S}}{\mathrm{A}^{(p-2)/p}\,c_0^{p-2}}\,\varepsilon^{(\mathrm{N}-2)/2}\,c_0\right. \\
&\qquad \left.\times\int_\Omega \frac{|u_0|^{p-2}\,u_0}{|x-a|^{\mathrm{N}-2}}\,\xi_a-\mathrm{B}\,c_0^2\,\mathrm{A}\,\delta_\varepsilon\right]+o\,[\varepsilon^{(\mathrm{N}-2)/2}] \\
&\quad = \mu_0+\sigma_0\,\frac{\mathrm{B}}{\mathrm{A}\,c_0^{p-2}}\left[\varepsilon^{(\mathrm{N}-2)/2}\,c_0\int_\Omega \frac{|u_0|^{p-2}\,u_0}{|x-a|^{\mathrm{N}-2}}\,\xi_a-c_0^p\,\mathrm{A}\,\delta_\varepsilon\right]+o\,[\varepsilon^{(\mathrm{N}-2)/2}].
\end{aligned}
$$

Finally, from (4.7) we conclude:

$$\mathrm{I}(u_0+c_\varepsilon \mathrm{U}_{\varepsilon, a})=\mu_0-\sigma_0 \frac{\mathrm{B}}{\mathrm{A}} c_0 u_0(a) \mathrm{D} \varepsilon^{(\mathrm{N}-2)/2}+o(\varepsilon^{(\mathrm{N}-2)/2}]<\mu_0$$

for $\varepsilon>0$ sufficiently small.
