## MODULES OVER A QUANTALE AND MODELS FOR THE OPERATOR ! IN LINEAR LOGIC

by *Kimmo I. ROSENTHAL*

**Résumé.** On démontre que la catégorie  $Mod(\mathbf{Q})$  des modules sur un quantale  $\mathbf{Q}$  (commutatif et unitaire) est un modèle de la logique linéaire pleine au sens de M. Barr. Ainsi, c'est une catégorie \*-autonome équipée d'un cotriple ! satisfaisant  $!(A \times B) \sim (!A) \otimes (!B)$  et  $!1 \sim \mathbf{Q}$ , où  $\mathbf{Q}$  en tant que  $\mathbf{Q}$ -module est l'unité pour  $\otimes$  dans  $Mod(\mathbf{Q})$ . Pour construire  $\mathbf{Q}$ , on utilise le foncteur libre pour les  $\mathbf{Q}$ -modules ainsi que des formules originellement données par R. Guitart.

### INTRODUCTION

\*-autonomous categories, originally investigated by Barr [2], have recently become the subject of much interest due to the fact that they provide categorical models for linear logic. Linear logic is a logic of resources developed by J.Y. Girard [6] which has potentially significant applications in theoretical computer science. The precise connection between \*-autonomous categories and linear logic was first clarified by Seely [12]. (Also, see Barr [3] and Blute [4].)

One particular aspect of the development of linear logic was the existence of the modal operator 'of course' denoted by !. Seely discussed in [12] some of the categorical properties that ! should possess and ! has been analyzed further by Barr [3] in his recent article. Following Barr, we say that a model of 'full' linear logic is a \*-autonomous category  $\mathcal{L}$  with finite products together with a cotriple  $(!, \epsilon, \delta)$  on  $\mathcal{L}$  satisfying that  $!(A \times B) \cong (!A) \otimes (!B)$  and  $!1 \cong \tau$ , where  $\tau$  is the unit for  $\otimes$  in  $\mathcal{L}$ .

Models for !, i.e. suitable cotriples on \*-autonomous categories, have not been easy to find. Girard's original coherent spaces provide a model ([6], [12]) and in [3] Barr discussed modifying the so-called Chu construction to obtain a model for !. Another potentially very interesting model has been investigated by Blute, Panagaden and Seely [5], where ! is modelled by the Fock space construction in functional analysis.

In this article, we provide a new family of models of full linear logic by considering modules over a commutative, unital quantale. Commutative, unital quantales are the commutative monoid objects in the \*-autonomous category  $Sl$  of sup-lattices. These quantales and their modules were studied by Joyal and Tierney [8]. (For an overview of the theory of quantales, see [9].)

If  $\mathcal{Q}$  is a commutative, unital quantale, the category  $Mod(\mathcal{Q})$ , of  $\mathcal{Q}$ -modules, is a  $*$ -autonomous category and we indicate how the free  $\mathcal{Q}$ -module functor from  $Sets$  to  $Mod(\mathcal{Q})$  extends to a cotriple  $! : Mod(\mathcal{Q}) \rightarrow Mod(\mathcal{Q})$  with the requisite structure to make  $Mod(\mathcal{Q})$  into a model of full linear logic. Our inspiration and calculations owe a debt to the early work of Guitart [7], where the free  $\mathcal{Q}$ -module construction is first described and the category  $Mod(\mathcal{Q})$  is analyzed in some detail. Guitart's theory of involutive monads deserves further study and may be relevant to developing other examples along these lines.

We begin by briefly describing a simple example, namely the category of sup-lattices. This examples serves to illuminate the more general construction in §2.

### §1. An example: the case of sup-lattices

The category  $Sl$  of sup-lattices is an example of a  $*$ -autonomous category. It was studied in detail by Joyal and Tierney [8] where the  $*$ -autonomous structure is described. The covariant power-set functor  $\mathcal{P} : Sets \rightarrow Sl$  is the free sup-lattice functor. It will give rise to a cotriple  $!$  on  $Sl$ , which will make  $Sl$  into a model of full linear logic, in the sense of Barr [3].

If  $M$  is a sup-lattice, define  $! : Sl \rightarrow Sl$  to be the covariant power-set functor. Thus,  $!M = \mathcal{P}(M)$ , the power set of  $M$ .

We have the following two maps:

$$\epsilon_M : \mathcal{P}(M) \rightarrow M \text{ defined by } \epsilon_M(A) = \text{sup} A \text{ for a subset } A \subseteq M$$

$$\delta_M : \mathcal{P}(M) \rightarrow \mathcal{P}(\mathcal{P}(M)) \text{ given by } \delta_M(A) = \{\{a\} | a \in A\}.$$

**Proposition:**  $(\mathcal{P}, \epsilon, \delta)$  defines a cotriple on  $Sl$ . Furthermore, for all sup-lattices  $A, B$ , it satisfies that  $\mathcal{P}(A \times B) \cong \mathcal{P}(A) \otimes \mathcal{P}(B)$ .

**Proof:** The fact that  $(\mathcal{P}, \epsilon, \delta)$  satisfies the appropriate diagrams for a cotriple is a straightforward exercise. The isomorphism  $\mathcal{P}(A \times B) \cong \mathcal{P}(A) \otimes \mathcal{P}(B)$  is discussed in [8] and follows directly from the fact that  $\mathcal{P}$  is the free sup-lattice functor.

**Corollary :** *The category  $Sl$  of sup-lattices, together with the cotriple  $(\mathcal{P}, \epsilon, \delta)$ , is a model of full linear logic.*

### §2. The general case: modules over a commutative unital quantale

A monoid in the category  $Sl$  is a sup-lattice  $\mathcal{Q}$  together with an associative binary operation  $\circ$  (with an identity element), which preserves sups in both variables. Such structures have been studied under the name *commutative unital quantale* (see [9] for an overview of quantale theory). Quantales are of interest in a variety of areas, in particular theoretical computer science (e.g. [1]) and linear logic ([9]).

**Definition 2.1.** Let  $\mathcal{Q}$  be a unital, commutative quantale. A  $\mathcal{Q}$ -module is a sup-lattice  $M$  together with a function  $\cdot : \mathcal{Q} \times M \rightarrow M$  such that

- 1)  $e \cdot m = m$  for all  $m \in M$ , where  $e$  is the identity of  $\mathcal{Q}$
- 2)  $q \cdot (r \cdot m) = (q \circ r) \cdot m$  for all  $q, r \in \mathcal{Q}, m \in M$
- 3)  $(\sup_{\alpha} q_{\alpha}) \cdot m = \sup_{\alpha} (q_{\alpha} \cdot m)$  for all  $\{q_{\alpha}\} \subseteq \mathcal{Q}, m \in M$ .
- 4)  $q \cdot (\sup_{\beta} m_{\beta}) = \sup_{\beta} (q \cdot m_{\beta})$  for all  $q \in \mathcal{Q}, \{m_{\beta}\} \subseteq M$ .

A sup-lattice morphism  $\psi : M \rightarrow N$  is a  $\mathcal{Q}$ -module morphism iff it satisfies  $\psi(q \cdot m) = q \cdot \psi(m)$  for all  $q \in \mathcal{Q}, m \in M$ .

Let  $Mod(\mathcal{Q})$  denote the category of  $\mathcal{Q}$ -modules. This category was also studied in [8] by Joyal and Tierney, and we record the following result.

**Theorem 2.1.**  $Mod(\mathcal{Q})$  is a \*-autonomous category.

The tensor product  $M \otimes_{\mathcal{Q}} N$  is the codomain of the universal bimorphism of modules  $M \times N \rightarrow M \otimes_{\mathcal{Q}} N$ , where a bimorphism is a  $\mathcal{Q}$ -module map in each variable separately.  $\mathcal{Q}$  is the unit object for  $\otimes_{\mathcal{Q}}$ .  $Hom_{\mathcal{Q}}(M, N)$  is the module of  $\mathcal{Q}$ -module morphisms  $M \rightarrow N$  with the obvious  $\mathcal{Q}$ -module structure.

We should point out that modules over quantales play a significant role in the categorical treatment of process semantics by Abramsky and Vickers [1].

When  $\mathcal{Q} = \mathbf{2}$ , (with  $\mathbf{2}$  the two element Boolean algebra), then it follows that  $Mod(\mathbf{2}) \cong SI$ . We would like to generalize the cotriple construction of §1 to this general setting of  $\mathcal{Q}$ -modules.

We first need to discuss the free  $\mathcal{Q}$ -module functor defined on *Sets*. The first details of this appear in the work of Guitart [7]. It is also discussed much more briefly in [8].

Let  $M$  be a set and let  $[M, \mathcal{Q}]$  denote the set of all functions (in *Sets*) from  $M$  to  $\mathcal{Q}$ .  $[M, \mathcal{Q}]$  becomes a  $\mathcal{Q}$ -module under the action  $(q \cdot f)(m) = q \cdot f(m)$  for all  $m \in M$ . Define  $! : Sets \rightarrow Mod(\mathcal{Q})$  by  $!(M) = [M, \mathcal{Q}]$ .  $!$  becomes a covariant functor as follows. If  $F : M \rightarrow N$  is a function, then define  $(!F) : [M, \mathcal{Q}] \rightarrow [N, \mathcal{Q}]$  by  $(!F)(f)(n) = \sup\{f(m) \mid F(m) = n\}$ .

That  $(!F)$  is a  $\mathcal{Q}$ -module morphism follows directly from the fact that in a quantale  $q \cdot ()$  preserves suprema.  $!$  lifts to a functor  $Mod(\mathcal{Q}) \rightarrow Mod(\mathcal{Q})$ .

We record the following result from Guitart [7].

**Theorem 2.2**  $! : Sets \rightarrow Mod(\mathcal{Q})$  is the free  $\mathcal{Q}$ -module functor.

We now wish to endow  $!$ , viewed as a functor from  $Mod(\mathcal{Q})$  to  $Mod(\mathcal{Q})$ , with the structure of a cotriple by generalizing the construction for sup-lattices (the case  $\mathcal{Q} = \mathbf{2}$ ). We shall need to utilize the following functions in  $[M, \mathcal{Q}]$ .

If  $m \in M$  and  $e \in \mathcal{Q}$  is the identity, define  $\eta_m : M \rightarrow \mathcal{Q}$  by  $\eta_m(x) = e$  if  $x = m$  and  $\eta_m(x) = 0$  if  $x \neq m$ .

To obtain a cotriple structure on  $!$ , we need to define appropriate  $\epsilon$  and  $\delta$ .

Define  $\epsilon_M : [M, \mathcal{Q}] \rightarrow M$  by  $\epsilon_M(f) = \sup\{f(m) \cdot m \mid m \in M\}$ .

Define  $\delta_M : [M, \mathcal{Q}] \rightarrow [[M, \mathcal{Q}], \mathcal{Q}]$  by  $\delta_M(f)(g) = f(m)$  if  $g = \eta_m$  for some  $m \in M$  and  $\delta_M(f)(g) = 0$  otherwise.

Both  $\epsilon_M$  and  $\delta_M$  are easily seen to be  $\mathcal{Q}$ -module morphisms.

We record the following simple lemma, which we shall need.

**Lemma 2.1** (1) *If  $M$  is a  $\mathcal{Q}$ -module and  $m \in M$ , then we have  $\delta_M(\eta_m) = \eta_{\eta_m}$ .*  
 (2) *Given  $g \in [M, \mathcal{Q}]$ , we have  $g = \sup_m \{g(m) \cdot \eta_m\}$ .*

**Theorem 2.3.** *( $!, \epsilon, \delta$ ) is a cotriple on  $Mod(\mathcal{Q})$ . Furthermore, we have for all  $\mathcal{Q}$ -modules  $M$  and  $N$  that  $(!M) \otimes (!N) \cong !(M \times N)$ , and  $!1 \cong \mathcal{Q}$ .*

Proof: First, to obtain a cotriple structure, we must verify that several equations hold. Given a  $\mathcal{Q}$ -module  $M$ , we first of all need to obtain the identity function on  $[M, \mathcal{Q}]$  from the following two maps.

$$\begin{aligned} \epsilon_{[M, \mathcal{Q}]} \circ \delta_M &: [M, \mathcal{Q}] \rightarrow [[M, \mathcal{Q}], \mathcal{Q}] \rightarrow [M, \mathcal{Q}] \\ (!\epsilon_M) \circ \delta_M &: [M, \mathcal{Q}] \rightarrow [[M, \mathcal{Q}], \mathcal{Q}] \rightarrow [M, \mathcal{Q}]. \end{aligned}$$

To see the first of these,  $\epsilon_{[M, \mathcal{Q}]}(\delta_M)(g) = \sup_f \{(\delta_M(g)(f) \cdot f)\}$ . But, if  $f \neq \eta_m$  for some  $m \in M$ , then  $(\delta_M(g)(f) = 0$ . Therefore, our supremum now becomes  $\sup_m \{(\delta_M(g)(\eta_m) \cdot \eta_m)\} = \sup_m \{g(m) \cdot \eta_m\}$ , by Lemma 2.1.

For the second equality, note that upon applying the functoriality of  $!$ , we obtain that  $(!\epsilon_M)(\delta_M)(g)(m) = \sup_f \{(\delta_M)(g)(f) \mid \epsilon_M(f) = m\}$ . But,  $(\delta_M)(g)(f)$  takes on the value 0 unless  $f = \eta_m$ , in which case we get  $g(m)$ . Since  $\epsilon_M(\eta_m) = m$ , it follows that  $(!\epsilon_M)(\delta_M)(g)(m) = g(m)$ , as desired.

The remaining conditions that need to be verified in checking that  $(!, \epsilon, \delta)$  defines a cotriple is that the two composites

$$!(\delta_M) \circ \delta_M : [M, \mathcal{Q}] \rightarrow [[M, \mathcal{Q}], \mathcal{Q}] \rightarrow [[[[M, \mathcal{Q}], \mathcal{Q}], \mathcal{Q}]$$

$$\delta_{[[M, \mathcal{Q}], \mathcal{Q}]} \circ \delta_M : [M, \mathcal{Q}] \rightarrow [[M, \mathcal{Q}], \mathcal{Q}] \rightarrow [[[[M, \mathcal{Q}], \mathcal{Q}], \mathcal{Q}]$$

are, in fact, equal. The latter map is most easily analyzed. For a function  $k \in [[M, \mathcal{Q}], \mathcal{Q}]$ , we have that  $(\delta_{[[M, \mathcal{Q}], \mathcal{Q}]})((\delta_M)(g)(k) = (\delta_M)(g)(f)$  provided  $k = \eta_f$  and is 0 otherwise. But,  $(\delta_M)(g)(f) = g(m)$  if  $f = \eta_m$  and is 0 otherwise. Piecing these facts together,  $(\delta_M)(\delta_M)(g)(k) = g(m)$  provided that  $k = \eta_{\eta_m}$  and is 0 otherwise.

We must now obtain this calculation for  $!(\delta_M) \circ \delta_M$ . By definition, we have that  $!(\delta_M)(\delta_M)(g)(k) = \sup_f \{(\delta_M)(g)(f) \mid (\delta_M)(f) = k\}$ . Since  $(\delta_M)(f) = 0$  unless  $f = \eta_m$ , this equals  $\sup_m \{g(m) \mid (\delta_M)(\eta_m) = k\}$ . But, by Lemma 2.1., we have that  $\delta_M(\eta_m) = \eta_{\eta_m}$  and if  $k = \delta_M(\eta_m) = \eta_{\eta_m}$ , it must be for a unique  $m$ . Thus, we have shown that  $!(\delta_M)(\delta_M)(g)(k) = g(m)$  if  $k = \eta_{\eta_m}$  and is 0 otherwise, proving that  $!(\delta_M)(\delta_M)(g) = (\delta_{[[M, \mathcal{Q}], \mathcal{Q}]})((\delta_M)(g)$  for all  $g$ , as desired. This finishes the verification that  $(!, \epsilon, \delta)$  forms a cotriple on  $Mod(\mathcal{Q})$ .

The assertion  $(!M) \otimes (!N) \cong !(M \times N)$  follows from the fact that  $!$  is the free  $\mathcal{Q}$ -module functor and that  $\otimes_{\mathcal{Q}}$  is left adjoint to  $Hom_{\mathcal{Q}}$ . For any  $\mathcal{Q}$ -module  $L$ , we have the following isomorphisms :  $Hom_{\mathcal{Q}}(!M \otimes_{\mathcal{Q}} !N, L) \cong Hom_{\mathcal{Q}}(!M, Hom_{\mathcal{Q}}(!N, L)) \cong$

$Sets(M, Hom_{\mathcal{Q}}(!N, L))$ . This, in turn, is isomorphic to  $Sets(M, Sets(N, L)) \cong Sets(M \times N, L) \cong Hom_{\mathcal{Q}}(1(M \times N), L)$ . This proves that  $(!M) \otimes (!N) \cong !(M \times N)$  and we are done

It may be possible to generalize this construction further as follows. By a *quantaloid* we mean a category  $\mathcal{Q}$  enriched in  $\mathcal{S}l$ . These are a natural generalization of unital quantales, which are quantaloids with one object. Much of the theory of quantales generalizes to quantaloids (see [11]), and it was recently shown in [10] that the notion of  $\mathcal{Q}$ -bimodule leads to a cyclic (non-symmetric) \*-autonomous category. A natural question to consider next is whether one can obtain a suitable model for ! on the category of  $\mathcal{Q}$ -bimodules, where  $\mathcal{Q}$  is a quantaloid.
