The Feynman path integral as an improper integral
over the Sobolev space

By

Daisuke Fujiwara

§ 1. Introduction.

Let $L(\dot{x}, x) = \frac{1}{2}|\dot{x}|^2 - V(x)$, be the Lagrangian with the potential $V(x)$. For the sake of simplicity of notations, we assume that the configuration space is of dimension 1. But the same results hold for n-dimensional case. The action of a path $r: [0, t] \rightarrow \mathbb{R}$, $r(0)=y$ and $r(t)=x$, with $\dot{r} \in L^2(0, t)$ is the functional

$$S(r) = \int_0^t L(\dot{r}, r) ds.$$

The Feynman path integral is a formal integral over the path space \mathcal{D} :

$$\int_{\mathcal{D}} e^{ih^{-1}S(r)} D[r].$$

Among various proposals to give mathematically rigorous meaning to the Feynman path integral, we adopt Itô's formulation [4] and [1].

Research partially supported by Grant-in Aid for General Scientific Research 01540108, The Ministry of Education

We denote by r_0 the straight line segment joining y and x , i.e.,

$$r_0(s) = \frac{s}{t}x + (1 - \frac{s}{t})y.$$

We denote the Sobolev space $H_0^1(0, t) = \{r : r \in L^2(0, t), r(0) = r(t) = 0\}$ by \mathcal{H} , which is equipped with the inner product

$$(r_1, r_2)_{\mathcal{H}} = \int_0^t \dot{r}_1(s) \dot{r}_2(s) ds.$$

Let $Q(r) = \sum_j \lambda_j e_j \otimes e_j$ be a positive quadratic form such that $\{e_j\}_j$ is a complete orthonormal system (c.o.n.s.) and $\{\lambda_j\}_j$ is a positive summable series. Let b be an arbitrary vector in \mathcal{H} . Let $N(dr, b, Q)$ be the Gaussian measure on \mathcal{H} with the mean b and the variance Q . Itô defined that

$$(1) \quad \int_{\Omega} e^{ih^{-1}S(r)} d[r] = \\ = (\frac{1}{2\pi i h t})^{1/2} \lim_{n \rightarrow \infty} \prod_{j=1}^{\infty} (1 + \frac{n\lambda_j}{hi})^{1/2} \int_{\mathcal{H}} e^{ih^{-1}S(r_0+r)} N(dr, b, nQ),$$

if the right hand side converges.

Unfortunately, existence of the limit on the right hand side of (1) was proved only for potentials $V(x)$ of the following two types:

$$1 \quad V(x) = ax^2 + bx + c.$$

$$2 \quad V(x) = \int e^{ix\xi} d\mu, \quad \text{where } \mu \text{ is a signed measure of finite total variation on } \mathbb{R}.$$

On the other hand Pauli [5] discussed the Feynman path integrals for potentials satisfying

$$|\text{grad } V(x)| = O(|x|) \quad \text{as } x \rightarrow \infty.$$

We assume in the present note a little stronger condition for the potential:

$$(2) \quad |v^{(j)}(x)| < c_j, \quad \text{if } 2 \leq j.$$

We use the special quadratic form

$$Q(r) = \sum_{j=1}^{\infty} \lambda^{-j} |(r, e_j)|^2,$$

where $\lambda > 1$ is a constant and $\{e_j\}_j$ is the c.o.n.s. consisting of indefinite integrals of Haars' functions. Our main results is

Theorem. Let Q be as above and b be any element of \mathcal{H} . We assume that V satisfy the condition (2). If $|t|$ is sufficiently small, then the right hand side of (1) converges to the limit independent of b . The limit $K(t, x, y)$ is the fundamental solution of the Schrödinger equation:

$$\left\{ \left(\frac{h}{i} \frac{\partial}{\partial t} \right) - \left(\frac{h}{i} \frac{\partial}{\partial x} \right)^2 - V(x) \right\} K(t, x, y) = 0,$$

$$K(0, x, y) = \delta(x-y).$$

Here h is a small positive constant.

In the next section we will give more accurate statement of the result as well as outline of the proof.

§ 2. Outline of the proof.

Indefinite integrals of Haars' functions.

Let $q = 2^{-n}(2k+1)$, $n=1, 2, 3, \dots$ and $k=0, 1, 2, \dots, 2^{n-1}-1$, be any finite binary fraction. We denote n by $n(q)$ and k by $k(q)$. We set $m(q) = 2^{n(q)-1} + k(q)$. For each such q , we define $\delta_q = 2^{-n(q)} t$ and

$$e_q(s) = \begin{cases} 0, & \text{for } |qt-s| \geq \delta_q, \\ (2\delta_q)^{-1/2} (\delta_q - |s - qt|) & \text{for } |s - qt| \leq \delta_q. \end{cases}$$

The system $\{\frac{d}{ds} e_q(s)\}_q$ is Haars' c.o.n.s. in $L^2(0, t)$. Hence $\{e_q\}$ forms a c.o.n.s. in \mathcal{H} . Note that

$$\|e_q\|_{L^\infty} = 2^{-1/2} \delta_q^{1/2}, \quad \|e_q\|_{L^1} = 2^{-1/2} \delta_q^{3/2}, \quad \|e_q\|_{L^2} = \frac{1}{2} \delta_q^{1/2}$$

The Quadratic form Q.

Let $\lambda > 1$. Then

$$Q(r) = \sum_q \lambda^{-m(q)} y_q^2, \quad \text{where } y_q = (r, e_q)_{\mathcal{H}}.$$

Splitting of \mathcal{H} .

Let $N_0 > \lambda+2$ be so large that

$$(2.1) \quad 2^N \lambda^{-2^{N-10}} < 1 \quad \text{for any } N \geq N_0.$$

We choose n so large that

$$(2.2) \quad n^{-1} \lambda^{2^{N_0}} < 1.$$

Let N_n be the positive integer such that

$$(2.3) \quad n^{-1} \lambda^{2^{N_n}} \leq 1 < n^{-1} \lambda^{2^{N_n+1}},$$

and m_n be the integer such that

$$(2.4) \quad n^{-1} \lambda^{m_n} < 2^{-N_n/4} < n^{-1} \lambda^{m_n+1}.$$

We can easily prove from (2.1), (2.3) and (2.4) that

$$(2.5) \quad 2^{N_n-1} < m_n < 2^{N_n+1}.$$

Let $\mathcal{H}_1 = \text{span of } \{e_q : m(q) < m_n\}$ and $\mathcal{H}_2 = \text{span of } \{e_q : m(q) \geq m_n\}$.

Then we have orthogonal decomposition

$$\mathcal{H} = \mathcal{H}_1 + \mathcal{H}_2,$$

which reduces the quadratic form Q . For any r in \mathcal{H} , we denote the corresponding decomposition

$$r = r_1 + r_2.$$

For any b in \mathcal{H} , the Gaussian measure $N(d\gamma, b, nQ)$ coincides with the product measure

$$N(d\gamma, b, nQ) = N(d\gamma_1, b_1, nQ_1) \times N(d\gamma_2, b_2, nQ_2).$$

New coordinates in \mathcal{H}_1 .

The subspace \mathcal{H}_1 is of

dimension $m_n - 1$. We arrange points $\{qt\}_{m(q) < m_n}$ of $[0, t]$ in its order of magnitude. Then we obtain a division of $[0, t]$ $0 < t_1 < t_2 < \dots < t_{m_1-1} < t$. We set $t_0 = 0$ and $t_{m_n} = t$. The subspace \mathcal{H}_1 coincides with the space of all piecewise linear paths with vertices at $s = t_j$, $j = 0, 1, \dots, m_n$. So we introduce a new

coordinates $x_j = r(t_j)$ of r with respect to the basis $\{w_j\}_j$, which is given by

$$w_j(s) = \begin{cases} 0 & \text{if } s \leq t_{j-1} \text{ or } t_{j+1} \leq s, \\ 1 & \text{if } s = t_j, \\ \text{linear} & \text{for } t_{j-1} \leq s \leq t_j \text{ and } t_j \leq s \leq t_{j+1}. \end{cases}$$

Any r_1 in \mathcal{H}_1 can be written into two forms:

$$r_1 = \sum_{m(q) < m_n} y_q e_q = \sum_{j=1}^{m_n-1} x_j w_j.$$

Evaluation of Itô's integral.

Let $b = b_1 + b_2$ be decomposition of b into \mathcal{H}_1 and \mathcal{H}_2 .

Using any $r = r_1 + r_2$, we make a new path $r_1 + b_2$. The action of it is

$$S(r_0 + r_1 + b_2) = \frac{1}{2} \int_0^t |\dot{r}_0|^2 ds + \|b_2\|_{\mathcal{H}}^2 + \|r_1\|_{\mathcal{H}}^2 - \int_0^t v(r_0 + r_1 + b_2) ds.$$

We can write this as

$$S(r_0 + r_1 + b_2) = \frac{1}{2} \frac{(x-t)^2}{2\Delta t_j} + \|b_2\|_{\mathcal{H}}^2 + \sum_{j=1}^{m_n} S_j(x_j, x_{j-1}; b_2),$$

where

$$S_j(x_j, x_{j-1}; b_2) = \frac{|x_j - x_{j-1}|^2}{2\Delta t_j} - \Delta t_j \omega_j(x_j, x_{j-1}; b_2)$$

with $\Delta t_j = t_j - t_{j-1}$ and

$$\omega_j(x_j, x_{j-1}; b_2) = (\Delta t_j)^{-1} \int_{t_{j-1}}^{t_j} v(x_j w_j + x_{j-1} w_{j-1} + r_0 + b_2) ds.$$

The Hessian $\text{Hess}(S)$ of $S(r_0+r_1+b_2)$ with respect to

x_1, \dots, x_{m_n-1} equals $\text{Hess}(S) = H - W = H(I - H^{-1}W)$, where

$$H = \begin{pmatrix} \frac{1}{\Delta t_1} + \frac{1}{\Delta t_2}, & -\frac{1}{\Delta t_2}, & 0, & 0, & \dots \\ -\frac{1}{\Delta t_2}, & \frac{1}{\Delta t_2} + \frac{1}{\Delta t_3}, & -\frac{1}{\Delta t_3}, & 0, & \dots \\ 0, & -\frac{1}{\Delta t_3}, & \frac{1}{\Delta t_3} + \frac{1}{\Delta t_4}, & -\frac{1}{\Delta t_4}, & \\ 0, & 0, & \dots & & \end{pmatrix}$$

and W is the Hessian of $\sum_{j=1}^{m_n} t_j \omega_j(x_j, x_{j-1}; b_2)$.

If $|t|$ is small $(I - H^{-1}W)$ is invertible. Hence the functional $r_1 \rightarrow S(r_0 + r_1 + b_2)$ has only one critical point at $r_1 = r_1^*$
 $= \sum_j x_j^* w_j$. which is given by

$$\partial_{x_j} S_j(x_j^*, x_{j-1}^*) + \partial_{x_j} S_{j+1}(x_{j+1}^*, x_j^*) = 0, \quad 1 \leq j \leq m_n - 1,$$

where $x_{m_n}^* = x_0^* = 0$.

For any finite binary fraction q with $m(q) > m_n$, we define

$$\xi_q(r_0 + r_1 + b_2) = \int_0^t v'(r_0(s) + r_1(s) + b_2(s)) e_q(s) ds$$

and $\xi_q^*(r_0 + b_2) = \xi_q(r_0 + r_1^* + b_2)$. The splitting $\mathcal{H} = \mathcal{H}_1 + \mathcal{H}_2$ reduces the quadratic form Q into Q_1 and Q_2 and it reduces the

Gaussian measure $N(d\gamma, b, nQ)$:

$$N(d\gamma, b, nQ) = N(d\gamma_1, b_1, nQ_1) \times N(d\gamma_2, b_2, nQ_2).$$

It is clear that

$$N(d\gamma_1, b_1, nQ_1) = \prod_{j=1}^{m_n-1} \left(\frac{1}{2\pi\Delta t_j} \right)^{1/2} \exp \left(-\frac{1}{2n} \sum_{m(q) < m_n} \lambda^m(q) (y_q - b_q)^2 \right) \prod_{j=1}^{m_n-1} dx_j.$$

The variance of this Gaussian measure is nQ_1 , which is large.

So the density of this with respect to the Lebesgue measure can be regarded as an amplitude of an oscillatory integral. On the other hand $N(d\gamma_2, b_2, nQ_2)$ has variance relatively small. The delta measure concentrated at $\gamma_2 = b_2$ is a good approximation to $N(d\gamma_2, b_2, nQ_2)$. Thus we have

Theorem 2.1. If $|t|$ is sufficiently small,

$$\begin{aligned} & (2\pi i h)^{-1/2} \prod_q \left(1 + \frac{n\lambda^{-m(q)}}{ih} \right)^{1/2} \int_{\mathcal{H}} e^{ih^{-1}S(r_0+r)} N(d\gamma, nQ, b) \\ &= \exp \left(-\frac{1}{2} \sum_{m(q) \geq m_n} \frac{n\lambda^{-m(q)}}{h^2 + i nh \lambda^{-m(q)}} (\xi_q^* - b_q)^2 - \sum_{m(q) < m_n} \frac{\lambda^m(q)}{2n} (y_q^* - b_q)^2 \right) \\ & \cdot \prod_{j=1}^{m_n} \left(\frac{1}{2\pi i h \Delta t_j} \right)^{1/2} \int_{R^{m_n-1}} e^{ih^{-1}S(r_0+r_1+b_2)} \prod_{j=1}^{m_n-1} dx_j \\ &+ \left(\frac{1}{2\pi i t h} \right)^{1/2} e^{ih^{-1}S(r_0+r_1^*+b_2)} r_n(t, x, y), \end{aligned}$$

where $y_q^* = (\gamma_1^*, e_q)_{\mathcal{H}}$. We have the estimate

$$|\partial_x^\alpha \partial_y^\beta r_n(t, x, y)| \leq C_{\alpha\beta}(h) 2^{-N_n/8} t.$$

The last term of the right hand side of Theorem goes to 0 as n goes to ∞ . While the exponential factor of the first term tends to 1 as n goes to ∞ . In fact we have

Theorem 2.2. Let $\delta_n = 2^{-N_n} t$. Then we have the following estimates:

$$\left| \partial_x^\alpha \partial_y^\beta \xi_q^* \right| \leq C_{\alpha\beta} \delta_n^{3/2} (1+|x|+|y|)^{(1-\alpha-\beta)^+},$$

$$\left| \sum_{m(q) \geq m_n} \frac{n \lambda^{-m(q)}}{h^2 + i n h \lambda^{-m(q)}} (\xi_q^* - b_q)^2 \right| < C(1+|x|^2 + |y|^2 + \|b_2\|_{\mathcal{H}}^2) \delta_n^{3/2}.$$

$$\left| \partial_x^\alpha \partial_y^\beta y_q^* \right| < C_{\alpha\beta} (1+|x|+|y| + \|b\|_{\mathcal{H}}) (1-\alpha-\beta)^+ \delta_n^{3/2}.$$

$$\sum_{m(q) < m_n} \frac{\lambda^{m(q)}}{n} (y_q^* - b_q)^2 < C(1+|x|^2 + |y|^2 + \|b_2\|_{\mathcal{H}}^2) \delta_n.$$

Here a^+ denotes $\max(a, 0)$.

Theorem 2.1 and Theorem 2.2 imply that the decisive role is played by the oscillatory integral

$$J_n = \prod_{j=1}^{m_n} \left(\frac{1}{2\pi i h \Delta t_j} \right)^{1/2} \int_{R^{m_n-1}} e^{ih^{-1} S(r_0 + r_1 + b_2)} \prod_{j=1}^{m_n-1} dx_j.$$

Similar integrals are treated previously in [3]. We have

Theorem 2.3. If $|t|$ is small enough, we can rewrite

$$J_n = \left(\frac{1}{2\pi i h t} \right)^{1/2} e^{ih^{-1} S(r_0 + r_1^* + b_2)} (1+k_n(t, x, y)),$$

For any $K > 0$, there exists C_K such that we have

$$|\partial_x^\alpha \partial_y^\beta k_n(t, x, y)| \leq \prod_{j=1}^{m_n} (1 + C_K |\Delta t_j| |t|)^{-1},$$

if α and β are smaller than K .

Convergence as n goes to ∞ . In order to discuss convergence of the oscillatory integral J_n . We compare $S(r_0 + r_1 + b_2)$ with the action of piecewise classical orbit. Let

$$\Delta : 0 = t_0 < t_1 < \dots < t_{m_n-1} < t_{m_n} = t$$

be the division of the $[0, t]$ as above. Let r_Δ be the piecewise classical orbit

$$\begin{aligned} r_\Delta(s) + \partial_x V(r_\Delta) &= 0 && \text{for } t_{j-1} < s < t_j, \\ r_\Delta(t_j) &= x_j + r_0(t_j), && \text{for } j = 0, 1, \dots, m_n, \end{aligned}$$

with $x_0 = x_{m_n} = 0$. The action along r_Δ is

$$S_{cl}(t, x, x_{m_n-1}, \dots, x_1, y) = \sum_{j=1}^{m_n-1} S_j(t_j, x_j, x_{j-1}),$$

where

$$S_j(t_j, x_j, x_{j-1}) = \int_{t_{j-1}}^{t_j} L(r_\Delta(s)) ds.$$

The critical point of $S_{cl}(t, x, x_{m_n-1}, x_{m_n-2}, \dots, x_1, y)$ with respect to vertices $x_{m_n-1}, x_{m_n-2}, \dots, x_1$ is unique if $|t|$ is small. The critical level of it equals the classical action

$$S_{cl}(t, x, y) = \int_0^t L(r_{cl}(s)) ds,$$

where r_{cl} is the classical orbit joining $r(0)=y$ and $r(t)=x$.

Theorem 2.4. If $|t|$ is small, we have

$$\prod_{j=1}^{m_n} \left(\frac{1}{2\pi i h \Delta t_j} \right)^{1/2} \int_{R^{m_n-1}} e^{ih^{-1} S_{cl}(t, x, x_{m_n-1}, \dots, x_1, y)} \prod_{j=1}^{m_n-1} dx_j \\ = \left(\frac{1}{2\pi i h t} \right)^{1/2} e^{ih^{-1} S_{cl}(t, x, y)} (1 + k^*(\Delta, t, x, y)).$$

For any $K > 0$, There exists a constant $C_K > 0$ such that

$$|\partial_x^\alpha \partial_y^\beta k^*(\Delta, t, x, y)| < \prod_{j=1}^{m_n} (1 + C_K \Delta t_j |t|) - 1,$$

if α and $\beta < K$.

The next theorem compares $k^*(\Delta, t, x, y)$ with $k_n(t, x, y)$.

Theorem 2.5. For any $K > 0$, there exists a constant C_K

such that

$$\left| \partial_x^\alpha \partial_y^\beta (k^*(\Delta, t, x, y) - k_n(t, x, y)) \right| < C \delta_n^{1/8} (1 + |x| + |y| + \|b_2\|_{\mathcal{H}}).$$

If we make the division of interval finer, $k^*(\Delta, t, x, y)$ forms a Cauchy sequence. More precisely, we have

Theorem 2.6. Let Δ_1 be a subdivision of Δ , then

$$|\partial_x^\alpha \partial_y^\beta (k^*(\Delta, t, x, y) - k^*(\Delta_1, t, x, y))| \leq C_K |t| |\Delta|,$$

where $|\Delta| = \max_{1 \leq j \leq m_n} |\Delta t_j|$. We set

$$k(t, x, y) = \lim_{|\Delta| \rightarrow 0} k^\#(\Delta, t, x, y).$$

Then $k(t, x, y)$ satisfies

$$\left| \partial_x^\alpha \partial_y^\beta k(t, x, y) \right| \leq C t.$$

Combining all these, we can prove

Theorem 2.7.

$$\begin{aligned} & \lim_{n \rightarrow \infty} (2\pi i h)^{-1/2} \prod_q (1 + \frac{n\lambda^{-m}(q)}{ih})^{1/2} \int_{\mathcal{H}} e^{ih^{-1}S(r_0+r)} N(dr, nQ, b) \\ &= \left(\frac{1}{2\pi i h} \right)^{1/2} e^{ih^{-1}S_{cl}(t, x, y)} (1 + k(t, x, y)), \end{aligned}$$

which is the fundamental solution of the Schrödinger equation.

Appendix

In proving above results, we use the following stationary phase method in a space of large dimension. We consider the following oscillatory integrals

$$I(S, a, \nu) = \prod_{k=1}^L \left(\frac{\nu}{2\pi i t_k} \right)^{1/2} \int_{\mathbb{R}^{L-1}} e^{i\nu S(x_L, \dots, x_0)} a(x_L, \dots, x_0) \prod_{j=1}^{L-1} dx_j.$$

The phase function $s(x_L, \dots, x_0)$ is a real valued function of the form

$$s(x_L, x_{L-1}, \dots, x_0) = \sum_{j=1}^{L-1} s_j(x_j, x_{j-1}),$$

with

$$s_j(x_j, x_{j-1}) = \frac{1}{2t_j} (x_j - x_{j-1})^2 + t_j \omega_j(x_j, x_{j-1}), \quad j=1, 2, \dots, L.$$

We assume further that

$$\sup_{x, y} \left| \partial_x^\alpha \partial_y^\beta \omega_j(x, y) \right| \leq C_{\alpha\beta},$$

if $0 \leq \alpha, \beta \leq K$ and $\alpha + \beta \geq 2$.

If $T = t_1 + t_2 + \dots + t_L$ is small enough, the critical point $(x_{L-1}^*, x_{L-2}^*, \dots, x_1^*)$ of the phase is the unique solution of

$$\partial_{x_j} s_{j+1}(x_{j+1}^*, x_j^*) + \partial_{x_j} s_j(x_j^*, x_{j-1}^*) = 0, \quad j=1, 2, \dots, L-1,$$

where $x_L^* = x_L$ and $x_0^* = x_0$. We use the following notation

$$a(\overline{x_L, x_0}) = a(x_L, x_{L-1}^*, \dots, x_1^*, x_0).$$

Let $k < l$ and $x_{k+1}^*, \dots, x_{l-1}^*$ be the partial critical point, i.e.,

$$\partial_{x_j} s_{j+1}(x_{j+1}^*, x_j^*) + \partial_{x_j} s_j(x_j^*, x_{j-1}^*) = 0, \quad \text{for } j=k+1, \dots, l-1,$$

where $x_k^* = x_k$ and $x_l^* = x_l$. Then we set

$$a(\overline{x_L, \dots, x_1, x_k, \dots, x_0}) = a(x_L, \dots, x_1, x_{l-1}^*, \dots, x_{k+1}^*, x_k, \dots, x_0).$$

We assume that for any sequence of positive integers

$$j_0=0 < j_1 < j_2 < \dots < j_r < L$$

and positive K we have the estimate

$$\left| \partial_{x_0}^{\alpha_0} \partial_{x_{j_1}}^{\alpha_1} \dots \partial_{x_{j_r}}^{\alpha_r} \partial_{x_L}^{\alpha_L} a(\overbrace{x_L, x_{j_s}, \dots, x_{j_{s-1}}, \dots, x_{j_1}, x_0}) \right| < A_K,$$

if each $\alpha_j \leq K$, $j=0, 1, \dots, r$ and L .

Theorem. Under the assumptions above there is a positive constant δ such that if $T=t_1+t_2+\dots+t_L < \delta$

$$I(S, a, \nu) = \left(\frac{\nu}{2\pi IT} \right)^{1/2} e^{i\nu S(x_L, x_0)} \det(I + H^{-1}W)^{-1/2} (a(x_L, x_0) + r(x_L, x_0)),$$

where $r(x_L, x_0)$ satisfies the estimate:

for any $\alpha_0, \alpha_L \leq K$,

$$\left| \partial_{x_0}^{\alpha_0} \partial_{x_L}^{\alpha_L} r(x_L, x_0) \right| \leq A_{3K+10} \left(\prod_{j=1}^L (1 + C_k \nu^{-1} |t_j| T) - 1 \right),$$

Constants δ and C_K are independent of the dimension L of the space. H is the matrix

$$H = \begin{bmatrix} \frac{1}{t_1} + \frac{1}{t_2}, & -\frac{1}{t_2}, & 0, & 0, & \dots, 0 \\ -\frac{1}{t_2}, & \frac{1}{t_2} + \frac{1}{t_3}, & -\frac{1}{t_3}, & 0, & \dots, 0 \\ 0, & -\frac{1}{t_3}, & \frac{1}{t_3} + \frac{1}{t_4}, & -\frac{1}{t_4}, & \dots \\ 0, & 0, & \dots & \end{bmatrix}$$

and W is the Hessian matrix of $\sum_j t_j \omega_j(x_j, x_{j-1})$ at the

critical point of $S(x_L, x_{L-1}, \dots, x_1, x_0)$ with respect to $x_{L-1}, x_{L-2}, \dots, x_1$.
