# THE TOPOLOGY OF NORMAL SINGULARITIES OF AN ALGEBRAIC SURFACE AND A CRITERION FOR SIMPLICITY 

By David MUMFORD

Let a variety $\mathrm{V}^{n}$ be embedded in complex projective space of dimension $m$. Let $\mathrm{P} \in \mathrm{V}$. About P , choose a ball U of small radius $\varepsilon$, in some affine metric $d s^{2}=\Sigma d x_{j}^{2}+\Sigma d y_{j}^{2}, z_{j}=x_{j}+i y_{j}$ affine coordinates. Let B be its boundary and $\mathrm{M}=\mathrm{B} \cap \mathrm{V}$. Then M is a real complex of dimension $2 n-\mathrm{I}$, and a manifold if P is an isolated singularity. The topology of M together with its embedding in B (=a2m-I-sphere) reflects the nature of the point P in V . The simplest case and the only one to be studied so far, to the author's knowledge, is where $n=1, m=2$, i.e. a plane curve (see [3], [14]). Then M is a disjoint union of a finite number of circles, knotted and linked in a 3 -sphere. There is one circle for each branch of V at P , the intersection number of each pair of branches is the linking number of the corresponding circles, and the knots formed by each circle are compound toroidal, their canonical decomposition reflecting exactly the decomposition of each branch via infinitely near points.

The next interesting case is $n=2, m=3$. One would hope to find knots of a 3 -sphere in a 5 -sphere in this case; this would come about if P were an isolated singularity whose normalization was non-singular. Unfortunately, isolated non-normal points do not occur on hyper-surfaces in any Cohen-MacCaulay varieties. What happens, however, if the normalization of P is non-singular, is that M is the image of a 3 -sphere mapped into a 5 -sphere by a map which (i) identifies several circles, and (ii) annihilates a ray of tangent vectors at every point of another set of circles. In many cases the second does not occur, and we have an immersion of the 3 -sphere in the 5 -sphere. It would be quite interesting to know Smale's invariant in $\pi_{3}\left(\mathrm{~V}_{3,5}\right)$ in this case (see [io]).

From the standpoint of the theory of algebraic surfaces, the really interesting case is that of a singular point on a normal algebraic surface, and $m$ arbitrary. M is then by no means generally $\mathrm{S}^{3}$ and consequently its own topology reflects the singularity P! In this paper, we shall consider this case, first giving a partial construction of $\pi_{1}(\mathrm{M})$ in terms of a resolution of the singular point P ; secondly we shall sketch the connexion between $H_{1}(M)$ and the algebraic nature of $P$. Finally and principally, we shall demonstrate the following theorem, conjectured by Abhyankar:

Theorem. - $\pi_{1}(\mathrm{M})=(e)$ if and only if P is a simple point of F (a locally normal surface); and F topologically a manifold at P implies $\pi_{1}(\mathrm{M})=(e)$.

## I. - ANALYSIS OF M AND PARTIAL GALCULATION OF $\boldsymbol{\pi}_{1}(\mathrm{M})$

A normal point P in F is given. A finite sequence of quadratic transformations plus normalizations leads to a non-singular surface $\mathrm{F}^{\prime}$ dominating F [ r 5 ]. The inverse image of P on $\mathrm{F}^{\prime}$ is the union of a finite set of curves $\mathrm{E}_{1}, \mathrm{E}_{2}, \ldots, \mathrm{E}_{n}$. By further quadratic transformations if necessary we may assume that all $\mathrm{E}_{i}$ are non-singular, and, if $i \neq j$, and $\mathrm{E}_{i} \cap \mathrm{E}_{j} \neq \varnothing$, then that $\mathrm{E}_{i}$ and $\mathrm{E}_{j}$ intersect normally in exactly one point, which does not lie on any other $\mathrm{E}_{k}$. This will be a great technical convenience.

We note at this point the following fundamental fact about $\mathrm{E}_{i}$ : the intersection matrix $\mathrm{S}=\left(\left(\mathrm{E}_{i}, \mathrm{E}_{j}\right)\right)$ is negative definite. (This could also be proven by Hodge's Index Theorem.)

Proof. - Let $\mathrm{H}_{1}$ and $\mathrm{H}_{2}$ be two hyperplane sections of $\mathrm{F}, \mathrm{H}_{1}$ through P , and $\mathrm{H}_{2}$ not (and also not through any other singular points of F ). Let $(f)=\mathrm{H}_{1}-\mathrm{H}_{2}$. Let $\mathrm{H}_{1}^{\prime}$ be the proper transform of $\mathrm{H}_{1}$ on $\mathrm{F}^{\prime}$, and $\mathrm{H}_{2}^{\prime}$ the total transform of $\mathrm{H}_{2}$. Then $\mathrm{H}_{2}^{\prime} \equiv \mathrm{H}_{1}^{\prime}+\Sigma m_{i} \mathrm{E}_{i}$, where $m_{i}>\mathrm{o}$, all $i$ (here $m_{i}$ is positive since $m_{i}=\operatorname{ord}_{\mathrm{E}_{i}}(f)$, $f$ a function that is regular and zero at P on F , and moreover P is the center of the valuation of $\mathrm{E}_{i}$ on F ).

Let $\mathrm{S}^{\prime}=\left(\left(m_{i} \mathrm{E}_{i} \cdot m_{j} \mathrm{E}_{j}\right)\right)=\mathrm{M} . \mathrm{S} . \mathrm{M}$, where M is the diagonal matrix with $\mathrm{M}_{i i}=m_{i}$. To prove $\mathrm{S}^{\prime}$ is negative definite is equivalent with the desired assertion. Now note (a) $\mathrm{S}_{i j} \geq \mathrm{o}$, if $i \neq j$, (b) $\sum_{i} \mathrm{~S}_{i j}^{\prime}=\sum_{i}\left(m_{i} \mathrm{E}_{i} \cdot m_{j} \mathrm{E}_{j}\right)=-\left(\mathrm{H}_{1}^{\prime} \cdot m_{j} \mathrm{E}_{j}\right) \leq \mathrm{o}$, all $j$. For any symmetric matrix $\mathrm{S}^{\prime}$, these two facts imply negative indefiniteness. To get definiteness, look closer: we know also (c) $\sum_{i} \mathrm{~S}_{i j}^{\prime}<\mathrm{o}$, for some $j$ (since $\mathrm{H}_{1}^{\prime}$ passes through some $\mathrm{E}_{j}$ ), and ( $d$ ) we cannot split ( $\mathrm{I}, 2, \ldots, n$ ) $=\left(i_{1}, i_{2}, \ldots, i_{k}\right) \cup\left(j_{1}, j_{2}, \ldots, j_{n-k}\right)$ disjointly so that $\mathrm{S}_{i_{a} j_{b}}^{\prime}=\mathrm{o}$, any $a, b$ (since $\mathrm{UE}_{i}$ is connected by Zariski's main theorem [16]). Now these together give definiteness: Say

$$
\begin{aligned}
\mathrm{o}=\sum_{i j} \alpha_{i} \alpha_{j} \mathrm{~S}_{i j}^{\prime} & =\Sigma \alpha_{i}^{2} \mathrm{~S}_{i i}^{\prime}+2 \sum_{i<j} \alpha_{i} \alpha_{j} \mathrm{~S}_{i j}^{\prime} \\
& =\sum_{j}\left(\sum_{i} \mathrm{~S}_{i j}^{\prime}\right) \alpha_{j}^{2}-\sum_{i<j} \mathrm{~S}_{i j}^{\prime}\left(\alpha_{i}-\alpha_{j}\right)^{2}
\end{aligned}
$$

where $\alpha_{i}$ are real. Then by $(c)$, some $\alpha_{j}=0$, and by $(d), \alpha_{i}=\alpha_{j}$, all $i, j$.
Our first step is a close analysis of the structure of M. We have defined it informally in the introduction in terms of an affine metric (depending apparently on the choice of this metric). Here we shall give a more general definition, and show that all these manifolds coincide, by virtue of having identical constructions by patching maps.

In the introduction, M is a level manifold of the positive $\mathrm{C}^{\infty}$ fcn.

$$
p^{2}=\left|Z_{1}\right|^{2}+\ldots+\left|Z_{n}\right|^{2},
$$

( $\mathrm{Z}_{i}$ affine coordinates near $\mathrm{P} \in \mathrm{F}$ ). Now notice that M may also be defined as the level manifolds of $p^{2}$ on the non-singular $\mathrm{F}^{\prime}$ ( $p^{2}$ being canonically identified to a fcn. on $\mathrm{F}^{\prime}$ ). It is as a "tubular neighborhood" of $\mathrm{UE}_{i} \subset \mathrm{~F}^{\prime}$ that we wish to discuss M . Now the general problem, given a complex $\mathrm{K} \subset \mathrm{E}^{n}$, Euclidean $n$-space, to define a tubular neighborhood,
has been attacked by topologists in several ways although it does not appear to have been treated definitively as yet. J. H. C. Whitehead [13], when K is a subcomplex in a triangulation of $\mathrm{E}^{n}$, has defined it as the boundary of the star of K in the second barycentric subdivision of the given triangulation. I am informed that Thom [II] has considered it more from our point of view: for a suitably restricted class of positive $\mathrm{C}^{\infty}$ fcns. $f$ such that $f(\mathrm{P})=0$ if and only if $\mathrm{P} \in \mathrm{K}$, define the tubular neighborhood of K to be the level manifolds $f=\varepsilon$, small $\varepsilon$. The catch is how to suitably restrict $f$; here the archtype for $f^{-1}$ may be thought of as the potential distribution due to a uniform charge on K . In our case, as we have no wish to find the topological ultimate, we shall merely formulate a convenient, and convincingly broad class of such $f$, which includes the $p^{2}$ of the introduction.

Let us say that a positive $\mathrm{C}^{\infty}$ real fcn. $f$ on $\mathrm{F}^{\prime}$ such that $f(\mathrm{P})=0$ iff $\mathrm{P} \in \mathrm{E}_{i}$, is admissible if

1) $\forall \mathrm{P} \in \mathrm{E}_{i}-\bigcup_{j \neq i} \mathrm{E}_{j}$, if $\mathrm{Z}=\mathrm{o}$ is a local equation for $\mathrm{E}_{i}$ near $\mathrm{P}, f=|\mathrm{Z}|^{2 n i} . g$, where $g$ is $\mathrm{C}^{\infty}$ and neither o nor $\infty$ near P .
2) If $\mathrm{P}_{i j}=\mathrm{E}_{i} \cap \mathrm{E}_{j}$, and $\mathrm{Z}=0, \mathrm{~W}=0$ are local equations for $\mathrm{E}_{i}, \mathrm{E}_{j}$ respectively then $f=|\mathrm{Z}|^{2 n i} .|\mathrm{W}|^{2 n j} . g$, where $g$ is $\mathrm{C}^{\infty}$ and neither o nor $\infty$ near $\mathrm{P}_{i j}$.

The following proposition is left to the reader.
Proposition: (i) If $\mathrm{F}^{\prime \prime}$ dominates $\mathrm{F}^{\prime}$, and $f$ is admissible for $\mathrm{UE}_{i}$ on $\mathrm{F}^{\prime}$, and $g: \mathrm{F}^{\prime \prime} \rightarrow \mathrm{F}^{\prime}$ is the canonical map, then $f$ og is admissible for $g^{-1}\left(\mathrm{UE}_{i}\right)$ on $\mathrm{F}^{\prime}$.
(ii) For a suitable $\mathrm{F}^{\prime \prime}$ dominating $\mathrm{F}^{\prime}, p^{2}$ is an admissible map for $g^{-1}\left(\mathrm{UE}_{i}\right)$.

Let me say, however, that in (ii), the point is to take $F^{\prime \prime}$ high enough so that the linear system of zeroes of the functions ( $\Sigma \alpha_{i} Z_{i}$ ) less its fixed components, has no base points.

What we must now show is that there is a unique manifold $\mathbf{M}$ such that, if $f$ is any admissible fcn., M is homeomorphic to $\{\mathrm{P} \mid f(\mathrm{P})=\varepsilon\}$ for all sufficiently small $\varepsilon$. Fix a fcn. $f$ to be considered. Notice that at each of the points $\mathrm{P}_{i j}$, there exist real $\mathrm{C}^{\infty}$ coordinates $\mathrm{X}_{i j}, \mathrm{Y}_{i j}, \mathrm{U}_{i j}, \mathrm{~V}_{i j}$, such that

$$
f=\left(\mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}\right)^{n_{i}}\left(\mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}\right)^{n_{j}} \alpha_{i j},
$$

$\alpha_{i j}$ a constant, valid in some neighborhood U given by

$$
\begin{aligned}
& \mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}<\mathrm{I} \\
& \mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}<\mathrm{I} .
\end{aligned}
$$

Assume $\mathrm{E}_{i}$ is $\mathrm{X}_{i j}=\mathrm{Y}_{i j}=0$, and $\mathrm{E}_{j}$ is $\mathrm{U}_{i j}=\mathrm{V}_{i j}=0$.
Our first trick consists of choosing a $\mathrm{C}^{\infty}$ metric ( $\left.d s\right)^{2}$ (depending on $f$ ), such that within

$$
\begin{gathered}
\mathrm{U}^{\prime}=\left\{\begin{array}{l}
\mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}<\mathrm{I} / 2 \\
\mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}<\mathrm{I} / 2
\end{array}\right\}, \\
d s^{2}=d \mathrm{X}_{i j}^{2}+d \mathrm{Y}_{i j}^{2}+d \mathrm{U}_{i j}^{2}+d \mathrm{~V}_{i j}^{2} .
\end{gathered}
$$

Such a metric exists, e.g. by averaging a Hodge metric with these Euclidean metrics by some partition of unity. Now let

be the normal 2-plane bundle to $\mathrm{E}_{i}$ and normal $\mathrm{S}^{1}$-bundle to $\mathrm{E}_{i}$ in $\mathrm{F}^{\prime}$ respectively. Consider the map $(\exp )_{i}: \mathrm{N}_{i} \rightarrow \mathrm{~F}^{\prime}$ obtained by mapping $\mathrm{N}_{i}$ into F along geodesics perpendicular to $\mathrm{E}_{i}$. Let $f_{i}=f_{0}(\exp )_{i}$. Now for every point $\mathrm{Q} \in \mathrm{E}_{i}-\mathrm{U}_{j \neq \imath} \mathrm{E}_{j}$, there is a neighborhood W of $\mathrm{Q} \in \mathrm{E}_{i}$, and an $\varepsilon_{0}$ such that if $\varepsilon<\varepsilon_{0}$, the locus $f_{i}(\mathrm{P})=\varepsilon, \pi_{i}(\mathrm{P}) \in \mathrm{W}$ cuts once each ray in $\pi_{i}^{-1}(\mathrm{~W})$ (because $f_{i}^{1 / n_{i}}$ is a well-defined pos. $\mathrm{C}^{\infty}$ fcn. vanishing on the zero cross-section, with non-degenerate Hessian in normal directions; this is the standard situation of Morse theory, see [9]). Consequently, for any $\mathrm{W} \subset \mathrm{E}_{i}$ open, such that $\mathrm{E}_{j} \cap \mathrm{~W}=\varnothing, j \neq i$, there is an $\varepsilon_{0}$ such that if $\varepsilon<\varepsilon_{0}$, the locus $f(\mathrm{P})=\varepsilon$ canonically contains a homeomorphic image of $\psi_{i}^{-1}(\mathrm{~W})\left(\right.$ recall $(\exp )_{i}$ is a local homeomorphism near the zero-section of $\mathrm{N}_{i}$ ). Therefore, we see that the manifold M for which we are seeking a definition independent of $f$, is to be put together out of pieces of $\mathrm{S}_{i}$; we need only seek its structure near $\mathrm{P}_{i j}$. Let us therefore look in $\mathrm{U}^{\prime}$. Let us fix neighborhoods $\mathrm{U}_{i j}$ of $\mathrm{P}_{i j} \in \mathrm{E}_{i}$ and $\mathrm{U}_{j i}$ of $\mathrm{P}_{i j} \in \mathrm{E}_{j}$ by $\left(\mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}\right)<\mathrm{I} / 4$ and $\left(\mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}\right)<\mathrm{I} / 4$ respectively. Let $\mathrm{E}_{k}^{*}=\mathrm{E}_{k}-\bigcup_{j \neq k} \mathrm{U}_{k j}$ for all $k$. Now choose $\varepsilon_{0}<\alpha_{i, j} / 8^{n_{i}+n_{j}}$ and so that if $\varepsilon<\varepsilon_{0}, f(\mathrm{P})=\varepsilon$ contains $\psi_{i}^{-1}\left(\mathrm{E}_{i}^{*}\right)$ and $\psi_{j}^{-1}\left(\mathrm{E}_{j}^{*}\right)$ canonically. Then in the local coordinates in $\mathrm{U}^{\prime}$ about $\mathrm{P}_{i j}, \psi_{i}^{-1}\left(\partial \mathrm{E}_{i}^{*}\right) \subset\{\mathrm{P} \mid f(\mathrm{P})=\varepsilon\}$ equals

$$
\left\{\left(\mathrm{X}_{i j}, \mathrm{Y}_{i j}, \mathrm{U}_{i j}, \mathrm{~V}_{i j}\right) \mid \mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}=\mathrm{I} / 4, \mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}=\left(\frac{4^{n j} \varepsilon}{\alpha_{i j}}\right)^{1 / n_{i}}\right\}
$$

and $\psi_{j}^{-1}\left(\partial \mathrm{E}_{j}^{*}\right) \subset\{\mathrm{P} \mid f(\mathrm{P})=\varepsilon\}$ equals

$$
\left\{\left(\mathrm{X}_{i j}, \mathrm{Y}_{i j}, \mathrm{U}_{i j}, \mathrm{~V}_{i j}\right) \mid \mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}=\mathrm{I} / 4, \mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}=\left(\frac{4^{n_{i}} \varepsilon}{\alpha_{i j}}\right)^{1 / n j}\right\}
$$

(because of the Euclidean character of the metric $d s^{2}$ near $\mathrm{P}_{i j}, \exp _{i}$ takes the simplest possible form!). Note $\left(\frac{4^{n j} \varepsilon}{\alpha_{i j}}\right)^{1 / n_{i}}<_{\mathrm{I}} / 8$. Therefore, we see that $\psi_{i}^{-1}\left(\mathrm{E}_{i}^{*}\right)$ and $\psi_{j}^{-1}\left(\mathrm{E}_{j}^{*}\right)$ are patched by a standard "plumbing fixture":

$$
\left\{(x, y, u, v) \mid\left(x^{2}+y^{2}\right) \leqslant \mathrm{I} / 4,\left(u^{2}+v^{2}\right) \leqslant \mathrm{I} / 4,\left(x^{2}+y^{2}\right)^{n} \cdot\left(u^{2}+v^{2}\right)^{m}=\varepsilon<\mathrm{I} / 8^{n+m}\right\}
$$

where $n$ and $m$ are integers.
One sees immediately that this is simply $\mathrm{S}^{1} \times \mathrm{S}^{1} \times[\mathrm{o}, \mathrm{I}]$, and if we set $\mathrm{M}_{i}^{*}=\psi_{i}^{-1}\left(\mathrm{E}_{i}^{*}\right)$, then it simply attaches $\partial \mathbf{M}_{i}^{*}$ to $\partial \mathbf{M}_{j}^{*}$. Moreover, what is this attaching? There is a coordinate system on both $\partial \mathrm{M}_{i}^{*}$ and $\partial \mathrm{M}_{j}^{*}$ via

$$
\begin{aligned}
& \left(\frac{\mathrm{X}_{i j}}{\left.\sqrt{\mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}}, \frac{\mathrm{Y}_{i j}}{\sqrt{\mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}}}\right)=\xi \in \mathrm{S}^{1} \text { (in the usual embedding in } \mathrm{E}^{2} \text { ) }}\right. \\
& \left(\frac{\mathrm{U}_{i j}}{\left.\sqrt{\mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}}, \frac{\mathrm{~V}_{i j}}{\sqrt{\mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}}}\right)=\eta \in \mathrm{S}^{1} \text { (in the usual embedding in } \mathrm{E}^{2} \text { ) }}\right.
\end{aligned}
$$

and relative to these coordinates, the attaching is readily seen to be the identity. To complete the invariant topological description of $M$, we need only to show that the cycles $\left\{\left(\xi, \eta_{0}\right) \mid \xi \in S^{1}, \eta_{0}\right.$ fixed $\}$ and $\left\{\left(\xi_{0}, \eta\right) \mid \xi_{0}\right.$ fixed, $\left.\eta \in S^{1}\right\}$ are invariantly determined (since an identification of 2 tori is determined up to isotopy by an identification of a basis of I -cycles). But on $\mathbf{M}_{i}^{*}$ for instance, the ist one is just the fibre of $\mathrm{S}_{i}$ over a point of $\mathrm{E}_{i}$, and the 2nd is the loop $\partial \mathrm{E}_{i}^{*}$ lifted to $\mathrm{S}_{i}$ so that it is contractible in $\psi_{i}^{-1}\left(\mathrm{U}_{i j}\right)$; similarly on $\mathrm{M}_{j}^{*}$, but vice versa.

This determines M uniquely. We have essentially found, moreover, not only M but also for any fixed $f$, maps

$$
\begin{aligned}
& \varphi:{\mathrm{M} \rightarrow \mathrm{UE}_{i}}^{\psi}:\{\mathrm{P} \mid \mathrm{o}<f(\mathrm{P}) \leqslant \varepsilon\} \rightarrow \mathrm{M}
\end{aligned}
$$

where $\psi$ induces a homeomorphism of any $\left\{\mathrm{P} \mid f(\mathrm{P})=\varepsilon^{\prime} \leqslant \varepsilon\right\}$ onto M. Namely, define $\varphi$ on $\mathrm{M}_{i}^{*}$ by $\psi_{i}$ : projection into $\mathrm{E}_{i}$, and in $\mathrm{U}^{\prime}$ near $\mathrm{P}_{i j}$, define it as follows (fig. I ):

$$
\begin{aligned}
\varphi\left(\left(\mathrm{X}_{i j}, \mathrm{Y}_{i j}, \mathrm{U}_{i j}, \mathrm{~V}_{i j}\right)\right)= & \left(\mathrm{o}, \mathrm{o}, \mathrm{U}_{i j}, \mathrm{~V}_{i j}\right) \in \mathrm{E}_{i} \text { if } \mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2} \geq \mathrm{I} / 4 \\
= & \left(\mathrm{o}, \mathrm{o}, p \mathrm{U}_{i j}, p \mathrm{~V}_{i j}\right) \in \mathrm{E}_{i} \text { if } \mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2} \leqslant \mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2} \leqslant \mathrm{I} / 4 \\
= & \left(p^{\prime} \mathrm{X}_{i j}, p^{\prime} \mathrm{Y}_{i j}, \mathrm{o}, \mathrm{o}\right) \in \mathrm{E}_{j} \text { if } \mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2} \leqslant \mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2} \leqslant \mathrm{I} / 4 \\
= & \left(\mathrm{X}_{i j}, \mathrm{Y}_{i j}, \mathrm{o}, \mathrm{o}\right) \in \mathrm{E}_{i} \text { if } \mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2} \geqslant \mathrm{I} / 4, \\
& p=\tau\left(\mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}, \mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}\right) \\
& p^{\prime}=\tau\left(\mathrm{U}_{i j}^{2}+\mathrm{V}_{i j}^{2}, \mathrm{X}_{i j}^{2}+\mathrm{Y}_{i j}^{2}\right)
\end{aligned}
$$

where
and where

$$
\tau(\alpha, \beta)=\frac{\beta-\alpha}{1-4 \alpha} .
$$

As for $\psi$, away from $\mathrm{P}_{i j}$, define $\psi$ by first (exp) $)_{i}^{-1}$, then the projection of $\mathrm{N}_{i}$ -(o-section) to $S_{i}$, and then the identification of $S_{i}$ into M ; near $\mathrm{P}_{i j}$, define it by identifying those points whose $\xi$ and $\eta$ coordinates are equal, and that have the same image in $\mathrm{E}_{i} \cup \mathrm{E}_{j}$ under the map $\varphi$.

Note that $\varphi$ induces a map $\varphi_{*}: \pi_{1}(\mathrm{M}) \rightarrow \pi_{1}\left(\mathrm{UE}_{i}\right)$, which is onto as all the "fibres" are connected ${ }^{(1)}$. In order not to be lost in a morass of confusion, we shall now restrict ourselves to computing only $\mathrm{H}_{1}$ in general, and $\pi_{1}$ only if $\pi_{1}\left(\mathrm{UE}_{i}\right)=(e)$. Note thats this last is equivalent to (a) $\mathrm{E}_{i}$ connected together as a tree (i.e. it never happens $\mathrm{E}_{1} \cap \mathrm{E}_{2} \neq \varnothing, \mathrm{E}_{2} \cap \mathrm{E}_{3} \neq \varnothing, \ldots, \mathrm{E}_{k-1} \cap \mathrm{E}_{k} \neq \varnothing, \mathrm{E}_{k} \cap \mathrm{E}_{1} \neq \varnothing$ and $k>2$ for some ordering of the $\left.\mathrm{E}_{i}^{\prime} \mathrm{s}\right),(b)$ all $\mathrm{E}_{i}$ are rational curves.

First, to compute $\mathrm{H}_{1}(\mathrm{M})$, start with $\mathrm{H}_{i}\left(\mathrm{UE}_{i}\right)$. Let $\mathrm{UE}_{i}$, as a graph, be $p$-connected,

[^0]i.e. there exist some $P_{1}, \ldots, P_{p}$ such that if these points are deleted from $U_{i}$, then $U E i$ becomes a tree, but this does not happen for fewer $P_{i}$. Choose such $P_{i}$, and to $U E_{i}-U P_{i}$, for each $\mathrm{P}_{i}$, add two points $\mathrm{P}_{i}^{\prime}$ and $\mathrm{P}_{i}^{\prime \prime}$, one to each $\mathrm{E}_{j}$ to which $\mathrm{P}_{i}$ belonged. The result, T , is, up to homotopy type, simply the wedge of the (closed) surfaces $\mathrm{E}_{i}{ }^{(1)} . \mathrm{UE}_{i}$ is itself obtained from T by identifying the $p$ pairs of points $\mathrm{P}_{i}^{\prime}, \mathrm{P}_{i}^{\prime \prime}$; therefore up to homotopy

Fig. I
type, it is the wedge of $\mathrm{E}_{i}$ and $p$ loops. Therefore $\mathrm{H}_{1}\left(\mathrm{UE}_{i}\right)=\mathbf{Z}^{p+2 \Sigma g_{i}}$, where $g_{i}$ is the genus of $\mathrm{E}_{i}$.

Now $\varphi_{*}$ induces an onto map $\mathrm{H}_{1}(\mathrm{M}) \rightarrow \mathrm{H}_{1}\left(\mathrm{UE}_{i}\right)$, by passing modulo the commutators. Let K be its kernel. Let $\alpha_{i}$ be the loop or cycle of M consisting of the fibre of Mover some point in $\mathrm{E}_{i}-\mathrm{U}_{j \neq i} \mathrm{E}_{j}$ with the following sense: if $f_{i}=\mathrm{o}$ is a local equation for $\mathrm{E}_{i}$,

$$
\int_{\alpha_{i}} \frac{d f_{i}}{f_{i}}=+2 \pi i
$$

or equivalently $\alpha_{i}$ as a loop about the origin of a fibre of the normal bundle $\mathrm{N}_{i}$ to $\mathrm{E}_{i}$ should have positive sense in its canonical orientation. I claim $\alpha_{i}$ generate K , and their relations are exactly $\Sigma\left(\mathrm{E}_{i} . \mathrm{E}_{j}\right) \alpha_{j}=\mathrm{o}, i=\mathrm{I}, \ldots, n$.

[^1]Proof. - First introduce the auxiliary cycles $\beta_{i j}$ on $\varphi^{-1}\left(\mathrm{E}_{i}\right)=\mathbf{M}_{i}$, whenever $\mathrm{E}_{i} \cap \mathrm{E}_{j}=\left(\mathrm{P}_{i j}\right) \neq \varnothing$. Namely, move the cycle $\alpha_{j}$ along the fibres until it lies on $\varphi^{-1}\left(\mathrm{P}_{i j}\right) \subset \mathrm{M}_{i}$, and there call it $\beta_{i j}$. By my construction of the patching of $\mathrm{M}_{i}$ and $\mathrm{M}_{i}$, we know that $\beta_{i j}$ is what I called $\eta$, while $\alpha_{i}$ is $\xi$. Now compute the subgroup $\mathrm{K}_{i}$ of $\mathrm{H}_{1}\left(\mathrm{M}_{i}\right)$ defined by

As above, let $\mathrm{U}_{i j}$ be a small disc on $\mathrm{E}_{i}$ about $\mathrm{P}_{i j}$, and $\mathrm{E}_{i}^{*}=\mathrm{E}_{i}-\mathrm{UU}_{i j}$, and $\mathrm{M}_{i}^{*}=\varphi^{-1}\left(\mathrm{E}_{i}^{*}\right)$. Then $\mathrm{M}_{i}^{*}$ is a deformation retract of $\mathrm{M}_{i}$, and is, on the one hand canonically the restriction of the bundle $S_{i}$ to $\mathrm{E}_{i}^{*}$, and on the other hand uncanonically homeomorphic to $\mathrm{S}^{1} \times \mathrm{E}_{i}^{*}$. In this last description, $\alpha_{i}$ is canonically identified to $\mathrm{S}^{1} \times($ point $)$, while $\beta_{i j}$ are identified to (point) $\times \partial\left(\mathrm{U}_{i j}\right)$ only up to adding a multiple of $\alpha_{i}$. Therefore we see that $\mathrm{K}_{i}$ is generated by $\alpha_{i}$, $\beta_{i j}$, with one relation ( ${ }^{1}$ )

$$
\sum_{j} \beta_{i j}+\mathrm{N} \alpha_{i}=\mathrm{o}, \text { some } \mathrm{N} .
$$

To evaluate N , note that $\beta_{i j}$ considered as cycles in $\mathrm{S}_{i}$ are locally contractible (i.e. in the neighborhood of $\varphi^{-1}\left(\mathrm{P}_{i j}\right)$ described by my plumbing fixture). It is well known that when the oriented fundamental 2-cycle of $\mathrm{E}_{i}$ is lifted to $\mathrm{S}_{i}$, its boundary is $\left(\mathrm{E}_{i}^{2}\right) \alpha_{i}$. Therefore, this same lifting in $\mathrm{M}_{i}^{*}$ will have boundary $\sum_{j} \beta_{i j}+\left(\mathrm{E}_{i}^{2}\right) \alpha_{i}$. Now by the Mayer-Vietoris sequence, $H_{1}(M)$ is generated by $H_{1}\left(M_{i}\right)$, hence $K$ is by $K_{i}$, and has extra relations imposed by the identification of cycles on $M_{i} \cap M_{j}$. Since $H_{1}\left(M_{i} \cap M_{j}\right)$ is generated by $\beta_{i j}$ and $\beta_{j i}$, these relations are implicit in our choice of generators.

As a consequence of our result, since $\operatorname{det}\left(\mathrm{E}_{i} \cdot \mathrm{E}_{j}\right)=\mu \neq \mathrm{o}, \mathrm{K}$ is a finite group of order $\mu$, and is the torsion subgroup of $\mathrm{H}_{1}(\mathrm{M})$.

Now consider the case $\mathrm{E}_{i}$ rational, and $\mathrm{UE}_{i}$ tree-like. We shall compute $\pi_{1}(\mathrm{M})$, using $\pi_{1}\left(\mathrm{M}_{i}\right)$ as building blocks. In order to keep these various groups, with their respective base points, under control, it is necessary to define a skeleton of basic paths leading throughout $\mathrm{E}_{i}$. Let $\mathrm{Q}_{i} \in \mathrm{E}_{i}-\underset{j \neq i}{ } \mathrm{E}_{j}$ be chosen as base point in $\mathrm{E}_{i}$. On $\mathrm{E}_{i}$, choose a path $l_{i}$ as illustrated in Diagram II touching on each $\mathrm{P}_{i j} \in \mathrm{E}_{i}$. Lift all the $l_{i}$ together into $\mathbf{M}$ by a map $s$, so that $\varphi\left(s\left(l_{i}\right)\right)=l_{i}$, and so that at $\varphi^{-1}\left(\mathrm{P}_{i j}\right), s\left(l_{i}\right) \cap s\left(l_{j}\right) \neq \varnothing$. Choose, e.g. $s\left(\mathrm{Q}_{1}\right)$ as base point for all of M. Let $\mathrm{G}=\mathrm{U} l_{i}$. Now the lifting $s$ enables us to give the following recipe for paths $\alpha_{i}$ :
I. Go along $s(\mathbf{G})$ from $s\left(\mathbf{Q}_{1}\right)$ to a point $\mathbf{P}$ in $\mathbf{M}_{i}$.
2. Go once around the fibre of $\mathrm{M}_{i}$ through P in the canonical direction explained above.
3. Go back to $s\left(\mathbf{Q}_{1}\right)$ along $s(\mathbf{G})$.

[^2]This is clearly independent of the choice of P .
Our result can now be stated: firstly, the $\alpha_{i}$ generate $\pi_{1}$; secondly, their only relations are (a) $\alpha_{i}$ and $\alpha_{j}$ commute if $\mathrm{E}_{i} \cap \mathrm{E}_{j} \neq \varnothing$, (b) if $k_{i}=\left(\mathrm{E}_{i}^{2}\right)$, and $\mathrm{E}_{i_{1}}, \mathrm{E}_{j_{2}}, \ldots, \mathrm{E}_{j_{m}}$ are those $\mathrm{E}_{j}$ intersecting $\mathrm{E}_{i}$, written in the order in which they intersect $l_{i}$, then

$$
e=\alpha_{j_{1}} \alpha_{j_{2}}, \ldots, \alpha_{j_{m}} \alpha_{i}^{k_{i}} .
$$

To prove this, we use the following theorem of Van Kampen (see [8], p. 30): if X and Y are subcomplexes of a complex Z , and $\mathrm{Z}=\mathrm{X} \cup \mathrm{Y}$, while $\mathrm{X} \cap \mathrm{Y}$ is connected, then $\pi_{1}(\mathrm{Z})$ is the free product of $\pi_{1}(\mathrm{X})$ and $\pi_{1}(\mathrm{Y})$ modulo amalgamation of the sub-

Fig. 2
groups $\pi_{1}(\mathrm{X} \cap \mathrm{Y})$. Now since $\mathrm{E}_{i}$ is tree-like, M can be gotten from the $\mathrm{M}_{i}$ by successively joining on a new $\mathrm{M}_{i}$ with connected intersection with the part so far built up. Let $\pi_{1}\left(\mathrm{M}_{i}\right)$ be mapped into $\pi_{1}(\mathbf{M})$ by mapping a loop in $\mathrm{M}_{i}$ with base point $s\left(\mathrm{Q}_{i}\right)$ to one in M with base point $s\left(\mathbf{Q}_{1}\right)$ by simply tagging on to both ends of it the section of $s(\mathbf{G})$ joining these two points. Then $\pi_{1}(\mathrm{M})$ is simply the free product of the $\pi_{1}\left(\mathrm{M}_{i}\right)$ with amalgamation of the loops in $\mathrm{M}_{i} \cap \mathrm{M}_{j}$. Now recalling the structure of $\mathrm{M}_{i}^{*}$, we have an exact sequence that splits:

$$
\mathrm{o} \rightarrow \pi_{1}\left(\mathrm{~S}^{1}\right) \rightarrow \pi_{1}\left(\mathrm{M}_{i}^{*}\right) \xrightarrow{\pi} \pi_{1}\left(\mathrm{E}_{i}^{*}\right) \rightarrow \mathrm{o}
$$

( $\mathbf{S}^{1}$ the fibre of $\mathbf{M}_{i}$, a I-sphere). The path $\alpha_{i}$ is clearly a generator of $\pi_{1}\left(S^{1}\right)$ here, and hence in the center of $\pi_{1}\left(\mathrm{M}_{i}^{*}\right)$.

Now the important thing to notice is that if $\mathrm{E}_{i}$ meets $\mathrm{E}_{j}$, then $\alpha_{j}$ in $\pi_{1}\left(\mathrm{M}_{j}\right)$ can be moved by modifying the point P on $s(\mathrm{G})$ where $\alpha_{j}$ detours around the fibre $\mathrm{S}^{1}$; in particular, it may do this at $s\left(l_{i}\right) \cap s\left(l_{j}\right)$. In that position the loop $\alpha_{j}$ may be regarded canonically as in $\pi_{1}\left(\mathbf{M}_{i}\right)$. Under the identification of $\pi_{1}\left(\mathbf{M}_{i}\right)$ to $\pi_{1}\left(\mathbf{M}_{i}^{*}\right)$ and the projection $\pi$ of this group onto $\pi_{1}\left(\mathrm{E}_{i}^{*}\right)$, what happens to the loop $\alpha_{j}$ ? Recalling the patching map on the boundaries of $\mathrm{M}_{i}^{*}$ and $\mathrm{M}_{j}^{*}$ which was examined above, we see that this path proceeds along $G$ from $Q_{i}$ to near $P_{i j}$, then circles around the boundary of $\mathrm{U}_{i j}$
in a positively oriented direction, then returns along $G$ to $Q_{i}$. Referring again to our diagram, we see the relation $e=\pi\left(\alpha_{j_{1}}\right) \cdot \pi\left(\alpha_{j_{2}}\right) \ldots . \pi\left(\alpha_{j_{m}}\right)$. Now it is well-known that these loops $\pi\left(\alpha_{j_{k}}\right)$ generate the fundamental group of the $m$-times punctured sphere, and that this is the unique relation. Consequently, looking at the above exact sequence, it is clear that $\alpha_{i}, \alpha_{i_{1}}, \ldots, \alpha_{i_{m}}$ (when distorted into $M_{i}$ as indicated above) generate $\pi_{1}\left(M_{i}\right)$. Moreover, the only relations among these generators are, therefore, that $\alpha_{i}$ and $\alpha_{j_{k}}$ commute, and $\alpha_{j_{1}} \ldots \ldots \alpha_{j_{m}} \in \pi_{1}\left(\mathrm{~S}^{1}\right)$, i.e. $=\alpha_{i}^{\mathrm{N}}$. But, using our results on $\mathrm{H}_{1}(\mathrm{M}), \mathrm{N}=-\left(\mathrm{E}_{i}^{2}\right)$.

It follows that $\alpha_{i}$ generate $\pi_{1}(\mathrm{M})$ with relations (a) and (b), and that the only additional relations are those coming from the amalgamation of $\pi_{1}\left(\mathbf{M}_{i} \cap \mathrm{M}_{j}\right)=\mathbf{Z}+\mathbf{Z}$. But $\alpha_{i}$ and $\alpha_{j}$ are generators here, and as loops in $\mathrm{M}_{i}$ and $\mathrm{M}_{j}$, these have already been identified. Hence we are through, Q.E.D.

## II. - ALGEBRO-GEOMETRIC SIGNIFIGANCE OF $\mathrm{H}_{1}$ (M)

## (a) Local Analytic Picard Varieties and Unique Factorization.

We shall study in this section two questions of algebro-geometric interest in the solution of which the topological structure of M , in particular its homological structure, is reflected. The first of these is the problem of the local Picard Variety at $\mathrm{P} \in \mathrm{F}$. Generally speaking, this, as a group, should be the group of local divisors at P modulo local linear equivalence to zero. (We shall be more precise below.) However, if by divisor one refers to an algebraic divisor and by local one means in the sense of the Zariski topology, one sees by example that the resulting group has little significance: it is not local enough. Ideally, one should mean by an irreducible local divisor a minimal prime ideal in the formal completion of the local ring of the point in question. However, I have been unable to establish the structure of the resulting Picard group. A compromise between these two groups is possible over the complex numbers. Take as divisors analytic divisors, and the usual complex topology to interpret local. There results a local analytic Picard variety that is quite accessible. In this section, we shall first analyze the group of local analytic divisors near $\mathrm{UE}_{i}$ modulo local linear equivalence and then consider the singular point $P$. Here by local analytic divisors we mean formal sums of irreducible analytic divisors defined in a neighborhood of $\mathrm{UE}_{i}$ (including the divisors $\mathrm{E}_{i}$ themselves). Such a sum, $\Sigma n_{i} \mathrm{D}_{i}$, is said to be locally linearly equivalent to zero if there exists a neighborhood U of $\mathrm{UE}_{i}$ where all $\mathrm{D}_{i}$ are defined and a meromorphic function $f$ on U such that $(f)=\Sigma n_{i}\left(\mathrm{D}_{i} \cap \mathrm{U}\right)$. This quotient we shall call the local analytic Picard Variety at $U_{i}$, or Pic $\left(U E E_{i}\right)$.

Denote by $\Omega$ the sheaf of germs of holomorphic functions on $\mathrm{F}^{\prime}$; by $\Omega^{*} \mathrm{C} \Omega$ the sheaf of germs of non-zero holomorphic functions. One has the usual exact sequence:

$$
\mathrm{o} \rightarrow \mathbf{Z} \rightarrow \Omega \xrightarrow{\exp (2 \pi i x)} \Omega^{*} \rightarrow 0
$$

where $\mathbf{Z}$ is the constant sheaf of integers. Let $\pi: \mathrm{F}^{\prime} \rightarrow \mathrm{F}$ be the regular projection from the non-singular surface $\mathrm{F}^{\prime}$ to the singular F .

Proposition. $-\operatorname{Pic}\left(\mathrm{UE}_{i}\right) \simeq\left(\mathrm{R}^{1} \pi\right)\left(\Omega^{*}\right)_{\mathrm{P}}$.
Proof. - Define $\operatorname{Pic}\left(\cup \mathrm{E}_{i}\right) \rightarrow\left(\mathrm{R}^{1} \pi\right)\left(\Omega^{*}\right)_{\mathrm{P}}$, by associating to $\Sigma n_{i} \mathrm{D}_{i}$, defined in $\mathrm{U} \supset \mathrm{UE}_{i}$, the following I -cocycle: assume $\mathrm{P} \in \mathrm{V}, \pi^{-1}(\mathrm{~V}) \subset \mathrm{U}$, assume $f_{j}$ is a local equation for $\Sigma n_{i} \mathrm{D}_{i}$ in $\mathrm{V}_{j},\left\{\mathrm{~V}_{j}\right\}$ a covering of V , then $\left\{f_{j_{1}} / f_{j_{2}}\right\} \in \mathrm{H}^{1}\left(\left\{\mathrm{~V}_{j}\right\}, \Omega^{*}\right)$ induces an $\alpha \in \mathrm{H}^{1}\left(\pi^{-1}(\mathrm{~V}), \Omega^{*}\right)$, hence an $\alpha^{\prime} \in\left(\mathbf{R}^{1} \pi\right)\left(\Omega^{*}\right)_{\mathrm{V}}$, hence an $\alpha^{\prime \prime} \in\left(\mathrm{R}^{1} \pi\right)\left(\Omega^{*}\right)_{\mathrm{P}}$. It is well known that $\alpha \in \mathrm{H}^{1}\left(\pi^{-1}(\mathrm{~V}), \Omega^{*}\right)$ is uniquely determined by $\Sigma n_{i} \mathrm{D}_{i}$, hence so is $\alpha^{\prime \prime}$.

To see that $\sum n_{i} \mathrm{D}_{i} \rightarrow \alpha^{\prime \prime}$ is $\mathrm{I}-\mathrm{I}$, say $\alpha^{\prime \prime}=\mathrm{o}$. Therefore $\exists \mathrm{V}^{\prime} \subset \mathrm{V}$ say, $\operatorname{Res}_{\mathrm{V}^{\prime}} \alpha^{\prime}=\mathrm{o}$, i.e. $\operatorname{Res}_{\pi^{-1}\left(\mathrm{~V}^{\prime}\right)}(\alpha)=0$. Therefore the covering $\left\{\mathrm{V}_{j} \cap \pi^{-1}\left(\mathrm{~V}^{\prime}\right)\right\}=\left\{\mathrm{V}_{j}^{\prime}\right\}$ has a refinement $\left\{\mathrm{V}_{k}^{\prime \prime}\right\}$ such that there exist non-zero functions $g_{k}$ on $\mathrm{V}_{k}^{\prime \prime}$ such that $g_{k_{1}} / g_{k_{2}}=f_{\tau k_{1}} / f_{\tau k_{2}}$ (for some map $\tau$ from the indices of $\left\{\mathrm{V}_{k}^{\prime \prime}\right\}$ to those of $\left\{\mathrm{V}_{j}\right\}$ such that $\left.\mathrm{V}_{k}^{\prime \prime} \subset \mathrm{V}_{\tau k}^{\prime}\right)$. Therefore $f=\frac{f_{\tau k}}{g_{k}}$
defines a function throughout $\pi^{-1}\left(\mathrm{~V}^{\prime}\right)$ such that $(f)=\Sigma n_{i} \mathrm{D}_{i}$.

To see that $\Sigma n_{i} \mathrm{D}_{i} \rightarrow \alpha^{\prime \prime}$ is onto $\left(\mathrm{R}^{1} \pi\right)\left(\Omega^{*}\right)_{\mathrm{P}}$, let $\beta^{\prime \prime} \in\left(\mathrm{R}^{1} \pi\right)\left(\Omega^{*}\right)_{\mathrm{P}}$ be represented by $\beta \in \mathrm{H}^{1}\left(\pi^{-1}(\mathrm{~V}), \Omega^{*}\right)$ and let this define the line bundle L over $\pi^{-1}(\mathrm{~V})$ in the usual way. Let $\mathscr{J}$ be the sheaf of germs of cross-sections of L: a coherent sheaf. Now by a result of Grauert and Remmert (cf. Borel-Serre [2], p. 104), $\left(\mathrm{R}^{0} \pi\right)(\mathscr{F})$ is coherent on F. But $\left(\mathbf{R}^{0} \pi\right)(\mathscr{J})$ is not the zero sheaf on $\mathbf{F}$ (at all points $\left.\mathrm{Q} \neq \mathrm{P}, \mathscr{J}_{Q} \simeq\left(\mathbf{R}^{0} \pi\right)(\mathscr{J})_{Q}\right)$, hence there exists some element $\mathrm{S} \in\left(\mathbf{R}^{0} \pi\right)(\mathscr{J})_{\mathrm{P}}, \mathrm{S} \neq \mathrm{o}$. S corresponds to a section in $\mathscr{J}_{\pi^{-1},\left(\mathrm{~V}^{\prime}\right)}$, for some open $\mathrm{V}^{\prime} \ni \mathrm{P}, \mathrm{V}^{\prime} \subset \mathrm{V}$. Therefore, the line bundle $\mathrm{L} \mid \pi^{-1}(\mathrm{~V})$ has a section S. But if $\beta$ is represented by a cocycle $f_{i j}$ with respect to a covering $\left\{\mathrm{V}_{i}\right\}$ of V , then S is given by a set of holomorphic functions $f_{i}$ on $\mathrm{V}_{i}$ such that $f_{j}=f_{i}\left(f_{i j}\right)$. It follows that $f_{i}=0$ define a divisor which is represented by $\beta$.
A. Grothendieck has posed the problem, for any proper map $f: \mathrm{V}_{1} \rightarrow \mathrm{~V}_{2}$ (onto), to define a relative Picard Variety of the map $f$. It seems clear, in the classical case, that if $\Omega^{*}$ is the sheaf of holomorphic units on $\mathrm{V}_{1},\left(\mathrm{R}^{1} f\right)\left(\Omega^{*}\right)$ is the logical choice although no nice properties have been established in general so far as the writer knows. In our case, $\left(\mathrm{R}^{1} f\right)\left(\Omega^{*}\right)_{Q}$, for $\mathrm{Q} \neq \mathrm{P}$, is simply ( I$)$, but at P , we have seen it to be $\operatorname{Pic}\left(\mathrm{UE}_{i}\right)$. We now wish to show that in our case, $\left(\mathbf{R}^{1} f\right)\left(\Omega^{*}\right)_{\mathrm{P}}$ is an analytic group variety. This is seen by the exact sequence for derived functors:

$$
\begin{aligned}
& \mathrm{o} \rightarrow\left(\mathrm{R}^{0} \pi\right)(\mathbf{Z}) \rightarrow\left(\mathrm{R}^{0} \pi\right)(\Omega) \xrightarrow{\varphi}\left(\mathbf{R}^{0} \pi\right)\left(\Omega^{*}\right) \rightarrow \\
& \rightarrow\left(\mathrm{R}^{1} \pi\right)(\mathbf{Z}) \xrightarrow{\stackrel{ }{\rightarrow}}\left(\mathbf{R}^{1} \pi\right)(\Omega) \rightarrow\left(\mathbf{R}^{1} \pi\right)\left(\Omega^{*}\right) \xrightarrow{\rightarrow} \\
& \rightarrow\left(\mathrm{R}^{2} \pi\right)(\mathbf{Z}) \rightarrow \ldots
\end{aligned}
$$

(i) Note first that if $x \in\left(\mathrm{R}^{0} \pi\right)\left(\Omega^{*}\right)_{\mathrm{P}}$, then $x$ is a non-zero function on $\pi^{-1}(\mathrm{~V})$, $\mathrm{P} \in \mathrm{V}$, and necessarily constant on $\mathrm{UE}_{i}$ which is connected and compact, therefore, at least on some $\pi^{-1}\left(\mathrm{~V}^{\prime}\right), \mathrm{P} \in \mathrm{V}^{\prime} \subset \mathrm{V}, x=\exp (2 \pi i y), y$ a holomorphic function on $\pi^{-1}\left(\mathrm{~V}^{\prime}\right)$, hence $x=\varphi(y), y \in\left(\mathrm{R}^{0} \pi\right)(\Omega)_{\mathrm{P}}$.
(ii) Note secondly that $\left(\mathbf{R}^{i} \pi\right)(\mathbf{Z})_{p} \simeq \mathrm{H}^{i}\left(\mathrm{UE}_{i}, \mathbf{Z}\right)$, since for $\mathrm{P} \in \mathrm{V}, \mathrm{V}$ small, $\pi^{-1}(\mathrm{~V})$ is contractible to $\mathrm{UE}_{i}$.
(iii) Note thirdly that if $i>0,\left(\mathrm{R}^{i} \pi\right)(\Omega)_{Q}=(\mathrm{o})$ for $\mathrm{Q} \neq \mathrm{P}$, and being a coherent sheaf, for $\mathrm{Q}=\mathrm{P}$ must be a finite dimensional vector space over $\mathbf{C}$.
(iv) Note fourthly that if $\gamma \in \mathrm{H}^{2}\left(\mathrm{UE}_{i}, \mathbf{Z}\right) \simeq\left(\mathbf{R}^{2} \pi\right)(\mathbf{Z})_{\mathrm{P}}$, there exists $\alpha \in\left(\mathbf{R}^{1} \pi\right)\left(\Omega^{*}\right)_{\mathrm{P}}$ such that $\psi \alpha=\gamma$. To show this, note that $H^{2}\left(\mathrm{UE}_{i}, \mathbf{Z}\right) \simeq \mathbf{Z}^{n},(n=$ number of irreducible curves in $\mathrm{UE}_{i}$ ) with generators $\gamma_{i}$ whose value on the 2-cycle $\mathrm{E}_{j}$ is $\delta_{i j}$; it is enough to verify it for the generators $\gamma_{i}$. But let $\mathrm{D}_{i}$ be an irreducible analytic curve through $Q \in \mathrm{E}_{i}-\bigcup_{j \neq i} \mathrm{E}_{i}$, with a simple point at Q , and tangent transversal to that of $\mathrm{E}_{i}$ at Q . If $\mathrm{D}_{i} \rightarrow \alpha_{i} \in\left(\mathrm{R}^{1} \pi\right)\left(\Omega^{*}\right)$, I claim $\psi \alpha_{i}=\gamma_{i}$. This is left to the reader. Therefore, we obtain

$$
\begin{gathered}
\mathrm{o} \rightarrow \mathrm{H}^{1}\left(\mathrm{UE}_{i}, \mathbf{Z}\right) \xrightarrow{\chi}\left(\mathrm{R}^{1} \pi\right)(\Omega)_{\mathrm{P}} \rightarrow \operatorname{Pic}\left(\mathrm{UE}_{i}\right) \rightarrow \mathrm{H}^{2}\left(\mathrm{UE}_{i}, \mathbf{Z}\right) \rightarrow \mathrm{o} \\
\sim \\
\mathbf{C}^{\mathrm{N}}, \text { some N. }
\end{gathered}
$$

(v) Note lastly that $\chi$ maps $\mathrm{H}^{1}\left(\mathrm{UE}_{i}, \mathbf{Z}\right)$ into a closed subgroup of $\left(\mathrm{R}^{1} \pi\right)(\Omega)_{\mathrm{P}}$, hence the connected component of $\operatorname{Pic}\left(\mathrm{UE}_{i}\right)$ is an analytic group. If this were false, there would be a real sum of elements of $\mathrm{H}^{\mathbf{1}}\left(\mathrm{UE}_{i}, \mathbf{Z}\right)$ that was zero without having to be, i.e. $\left\{\alpha_{i j}\right\} \in \mathrm{H}^{1}\left(\pi^{-1}(V), \mathbf{R}\right)$ (with respect to some covering $\left\{\mathrm{U}_{i}\right\}$ ) such that $\left\{\alpha_{i j}\right\} \sim 0$ in the sheaf $\Omega$ (in some $\pi^{-1}\left(\mathrm{~V}^{\prime}\right), \mathrm{V}^{\prime} \subset \mathrm{V}$ ). In other words, $\alpha_{i j}=f_{i}-f_{j}, f_{i}$ holomorphic in $\mathrm{U}_{i}$. But let $p_{i}$ be a real, $\mathrm{C}^{\infty}$ function on $\mathrm{U}_{i}$ such that $\alpha_{i j}=p_{i}-p_{j}$ (Poincaré's lemma). Then $f_{i}-p_{i}=\mathrm{F}, d f_{i}=\omega$ and $d p_{i}=\eta$, are defined all over $\pi^{-1}\left(\mathrm{~V}^{\prime}\right), \omega-\eta=d \mathrm{~F}$. I claim actually all the periods of $\eta$ are zero (which implies $\eta=d f$, and $\left\{\alpha_{i j}\right\} \sim 0$ in $\mathrm{H}^{1}\left(\mathrm{UE}_{i}, \mathbf{R}\right)$ and we are through $)$. First of all, the periods of $\eta$ equal those of $\omega$. Look at its periods on the I-cycles of any $\mathrm{E}_{i}$ : since $\eta$ is real, all the periods of the holomorphic differential $\omega$ are also real. But it is wellknown that then all the periods of $\omega$ must be identically zero, and therefore $\omega$ reduces to zero on paths in $\mathrm{E}_{i}$. Since this is true for all $i$, $\omega$ has no periods along any path in $\mathrm{UE}_{i}$, and since $\pi^{-1}\left(\mathrm{~V}^{\prime}\right)$ is contractible to $\mathrm{UE}_{i}$, $\omega$ has no periods at all. Therefore neither does $\eta$ and we are through.

There is another way of looking at $\operatorname{Pic}\left(\mathrm{UE}_{i}\right)$. Namely, let o be the local ring of (convergent) holomorphic functions at P , i.e. $\left(\mathrm{R}^{\theta} \pi\right)(\Omega)_{\mathrm{P}}$ (by the theorem of Riemann, cf. the report of Behnke and Grauert ([1], p. 18)). Now every divisor $\mathrm{D}^{\prime}$ in $\pi^{-1}\left(\mathrm{~V}^{\prime}\right)$, except for the $\mathrm{E}_{i}$ 's, defines a divisor D in $\mathrm{V}^{\prime}$, hence a minimal prime ideal $\mathfrak{p}$ in $\mathfrak{o}$. Let us set $\operatorname{Pic}(\mathrm{P})$ equal to the group of ideal classes in $\mathbf{0}$ : i.e. to the semi-group of pure rank I ideals $\mathfrak{a}$ of $\mathfrak{o}$, modulo the principal ideals ${ }^{(1)}$. Then the association of D to $\mathfrak{p}$ defines a map from $\operatorname{Pic}\left(\mathrm{UE}_{i}\right) \rightarrow \operatorname{Pic}(\mathrm{P})$, (if we define the image of each $\mathrm{E}_{i}$ to be ( I ), the identity). This is quite clear once one sees that every meromorphic function $f$ in $\pi^{-1}(\mathrm{~V})$ is a quotient

[^3]of two holomorphic functions in some $\pi^{-1}\left(\mathrm{~V}^{\prime}\right), \mathrm{V}^{\prime} \subset \mathrm{V}$ : but given $f$, consider the coherent sheaf $\mathscr{J}$ given by $\{g \mid(f g)$ is a positive divisor $\} . \quad\left(\mathrm{R}^{0} \pi\right)(\mathscr{J})$ is coherent, hence there exists $g_{1} \in\left(\mathbf{R}^{0} \pi\right)(\mathscr{J})_{\mathrm{P}}$, and if $f g_{1}=g_{2}$, then $f=g_{2} / g_{1}$ is the desired decomposition. Now the map $\operatorname{Pic}\left(\mathrm{UE}_{i}\right) \rightarrow \operatorname{Pic}(\mathrm{P})$ is onto as every minimal prime ideal $\mathfrak{p c o}$ defines some divisor through P . Its kernel is immediately seen to be generated by the $\mathrm{E}_{i}$ themselves. Hence we see

Proposition:

$$
\frac{\operatorname{Pic}\left(\mathrm{UE}_{i}\right)}{\left\{\mathrm{\Sigma n}_{i} \mathrm{E}_{i}\right\}} \simeq \operatorname{Pic}(\mathrm{P})
$$

Corollary. - We have

$$
\mathrm{o} \rightarrow \mathrm{H}^{1}\left(\mathrm{UE}_{i}, \mathbf{Z}\right) \rightarrow\left(\mathrm{R}^{1} \pi\right)(\Omega)_{\mathrm{P}} \xrightarrow{\varphi} \operatorname{Pic}(\mathrm{P}) \xrightarrow{山} \mathrm{H}_{1}(\mathrm{M})_{0} \rightarrow \mathrm{o}
$$

where $H_{1}(M)_{0}=$ torsion subgroup of $H_{1}(M)$ and $\psi$ associates to the divisor D through P , the i-cycle $\mathrm{D} \cap \mathrm{M}$.

Proof of Corollary: Note that $\Sigma n_{i} \mathrm{E}_{i}$ is never in the image of $\left(\mathrm{R}^{1} \pi\right)(\Omega)_{\mathrm{P}}$ since that would require $\left(\Sigma n_{i} \mathrm{E}_{i}, \mathrm{E}_{j}\right)=\mathrm{o}$ for all $j$. To see the exactness at $\psi$, note that the co-kernel of $\varphi$ is obtained by associating to a divisor $\Sigma n_{i} \mathrm{D}_{i}$ (where we may assume $\mathrm{E}_{i} \cap \mathrm{E}_{j} \cap\left(\right.$ USupp $\left._{l} \mathrm{D}_{l}\right)=\varnothing$, all $\left.i \neq j\right)$ the formal sum

$$
\sum_{k}\left(\sum_{i} n_{i} \mathrm{D}_{i} \cdot \mathrm{E}_{k}\right) \gamma_{k} \operatorname{modulo}\left\{\sum_{k}\left(\mathrm{E}_{i} \cdot \mathrm{E}_{k}\right) \gamma_{k}\right\},
$$

the $\gamma_{k}$ as in (iv) above. But $\psi$ is given by associating to $\Sigma n_{i} \mathrm{D}_{i}$, the element

$$
\sum_{k}\left(\sum n_{i} \mathrm{D}_{i} \cdot \mathrm{E}_{k}\right) \alpha_{k},
$$

in terms of our basis for $\mathrm{H}_{1}(\mathrm{M})_{0}$ in (I); but by our enumeration of the relations on the $\alpha_{k}$ we see $\gamma_{k}$ can be interchanged with $\alpha_{k}$.

Do these results have purely algebraic counterparts? First, note that it is hopeless to expect that the ideal structure of $\mathrm{D}_{0}$ (=algebraic local ring of P on F ) will reflect the homology of the singularity so well. This is seen in the following example: Take a non-singular cubic curve E in the projective plane, and let $\mathrm{P}_{1}, \ldots, \mathrm{P}_{15}$ be points on E in general position except that on E the divisor $\Sigma_{1}^{15} \mathrm{P}_{i} \equiv 5 \times$ (plane section). Blow up every point $P_{i}$ to a divisor $E_{i}$, and call $F^{\prime}$ the resulting surface. On $F^{\prime}$, the proper transform $\mathrm{E}^{\prime}$ of E is exceptional: it is shrunk by the linear system of quintics through the $P_{i}$. Then $E_{i}-E_{j}$ as a divisor in $\operatorname{Pic}\left(\mathrm{E}^{\prime}\right)$ is in the component of the identity, but as an algebraic divisor is not algebraically locally equivalent to zero: in fact $F^{\prime}$ is regular, hence algebraic and linear equivalence are the same, but since $\operatorname{Tr}_{\mathrm{E}^{\prime}}\left(\mathrm{E}_{i}-\mathrm{E}_{j}\right) \not \equiv \mathrm{o}, \mathrm{E}_{i}-\mathrm{E}_{j}$ is not locally linearly equivalent to zero.

However, I conjecture that the ideal class group of $\mathfrak{v}^{*}$ ( $=$ completion of $\mathfrak{v}_{0}$ and $\mathfrak{p}$ ) is identical to that of $\mathfrak{p}$, and that sums of formal branches through $\mathrm{UE}_{i}$ modulo holomorphic linear equivalence (in the sense of Zariski [ ${ }^{17}$ ]) gives $\operatorname{Pic}\left(\mathrm{UE}_{i}\right)$. If this is so, it should give $\operatorname{Pic}\left(\mathrm{UE}_{i}\right)$ an algebraic structure, which would be a decided improvement on our results. At present, I am unable to prove these statements.

## (b) Intersection Theory on Normal Surfaces.

We consider here the problem of defining, for divisors $\mathrm{A}, \mathrm{B}$ through P on $\mathrm{F},(a)$ total transforms $\mathrm{A}^{\prime}, \mathrm{B}^{\prime}$ on $\mathrm{F}^{\prime}$, and (b) intersection multiplicities $i(\mathrm{~A} . \mathrm{B} ; \mathrm{P})$. This problem has been posed by Samuel (see [7]) and considered by J. E. Reeve [19]. In this case, I suggest the following as a canonical solution:
a) To define $\mathrm{A}^{\prime}=\mathrm{A}_{0}^{\prime}+\Sigma r_{i} \mathrm{E}_{i}$, where $\mathrm{A}_{0}^{\prime}$ is the proper transform of A , require

$$
\left(\mathrm{A}^{\prime} . \mathrm{E}_{i}\right)=\mathrm{o}, i=\mathrm{1}, 2, \ldots, n,
$$

or

$$
\left(\mathrm{A}_{0}^{\prime} \cdot \mathrm{E}_{i}\right)+\sum_{j} r_{j}\left(\mathrm{E}_{j} . \mathrm{E}_{i}\right)=\mathrm{o}, i=\mathrm{I}, 2, \ldots, n .
$$

Since $\operatorname{det}\left(\mathrm{E}_{i} \cdot \mathrm{E}_{j}\right)=\mu \neq 0$, this has a unique solution.
b) To define $i(\mathrm{~A} . \mathrm{B} ; \mathrm{P})$, set it equal to

$$
\begin{gathered}
\quad\left(\mathrm{A}^{\prime} \cdot \mathrm{B}^{\prime}\right) \text { over } \mathrm{P} \\
=\sum_{\mathrm{P}^{\prime} \text { over } \mathrm{P}}\left[i\left(\mathrm{~A}_{0}^{\prime} \cdot \mathrm{B}_{0}^{\prime} ; \mathrm{P}^{\prime}\right)+\Sigma r_{i} i\left(\mathrm{E}_{i} \cdot \mathrm{~B}_{0}^{\prime} ; \mathrm{P}^{\prime}\right)\right] \\
=\sum_{\mathrm{P}^{\prime} \text { over } \mathrm{P}}\left[i\left(\mathrm{~A}_{0}^{\prime} \cdot \mathrm{B}_{0}^{\prime} ; \mathrm{P}^{\prime}\right)+\Sigma s_{i} i\left(\mathrm{~A}_{0}^{\prime} \cdot \mathrm{E}_{i} ; \mathrm{P}^{\prime}\right)\right]
\end{gathered}
$$

where

$$
\mathrm{A}^{\prime}=\mathrm{A}_{0}^{\prime}+\Sigma r_{i} \mathrm{E}_{i} ; \quad \mathrm{B}^{\prime}=\mathrm{B}_{0}^{\prime}+\Sigma s_{i} \mathrm{E}_{i} .
$$

We note the following properties:
(i) $\mathrm{A}=(f)_{\mathrm{F}}$, then $\mathrm{A}^{\prime}=(f)_{\mathrm{F}^{\prime}}$; hence $\mathrm{A} \equiv \mathrm{B}$ implies $\mathrm{A}^{\prime} \equiv \mathrm{B}^{\prime}$.

Proof. - For $\left((f)_{\mathrm{F}^{\prime}}, \mathrm{E}_{i}\right)=0$.
(ii) A effective, then all $r_{i}$ are positive.

Proof. - Say some $r_{i} \leq \mathrm{o}$. Say also $r_{i} / m_{i} \leq r_{j} / m_{j}$, all $j$, where the $m_{j}$ are the same as in the proof of negative definiteness. Then we see:

$$
\begin{aligned}
& \mathrm{o} \geq \sum_{j} r_{j}\left(\mathrm{E}_{j} \cdot \mathrm{E}_{i}\right)=\sum_{j} r_{j} / m_{j}\left(m_{j} \mathrm{E}_{j} \cdot \mathrm{E}_{i}\right), \\
& \geq r_{i} / m_{i} \sum_{j}\left(m_{j} \mathrm{E}_{j} \cdot \mathrm{E}_{i}\right) \geq \mathrm{o} .
\end{aligned}
$$

Therefore, if $\mathrm{E}_{i} \cap \mathrm{E}_{j} \neq \varnothing, r_{i} / m_{i}=r_{j} / m_{j}$ and $r_{j} \leq \mathrm{o}$. As $\cup \mathrm{E}_{i}$ is connected, this gives ultimately $r_{i} / m_{i}=\mathrm{R}$, independent of $i$. But then also $\left(\Sigma m_{j} \mathrm{E}_{j} . \mathrm{E}_{i}\right)=\mathrm{o}$, all $i$, which contradicts property (c) in the proof just referred to.
(iii) $i(\mathrm{~A} . \mathrm{B} ; \mathrm{P})$ is symmetric and distributive.
(iv) A and B effective, then $i(\mathrm{~A} . \mathrm{B} ; \mathrm{P})$ is greater than $o$.
(v) $i(\mathrm{~A} . \mathrm{B} ; \mathrm{P})$ independent of the choice of $\mathrm{F}^{\prime}$.

Proof. - To show this, it suffices, since any two non-singular models are dominated by a third, see Zariski [15], to compare $\mathrm{F}^{\prime}$ with $\mathrm{F}^{\prime \prime}$ gotten by blowing up some point $\mathrm{P}^{\prime}$ over P. But let $\mathrm{A}^{\prime}, \mathrm{B}^{\prime}$ be the total transforms of $\mathrm{A}, \mathrm{B}$ on $\mathrm{F}^{\prime}$, and $\mathrm{A}^{\prime \prime}, \mathrm{B}^{\prime \prime}$ those on $\mathrm{F}^{\prime \prime}$, and let $T$ be the map from $F^{\prime \prime}$ to $F^{\prime}$. Then with respect to $T, A^{\prime \prime}$ is the total transform
of $\mathrm{A}^{\prime}$ on $\mathrm{F}^{\prime \prime}$, and $\mathrm{B}^{\prime \prime}$ that of $\mathrm{B}^{\prime}$. In that case it is well-known that, for any point set $S$ in $\mathrm{F}^{\prime}$ (including all the points of any common components of $\left.\mathrm{A}^{\prime}, \mathrm{B}^{\prime}\right),\left(\mathrm{A}^{\prime} \cdot \mathrm{B}^{\prime}\right)_{\mathrm{S}}=\left(\mathrm{A}^{\prime \prime} \cdot \mathrm{B}^{\prime \prime}\right)_{\mathrm{T}^{-1}(\mathrm{~S})}$.
(vi) $\mathrm{A}^{\prime}$ is integral if and only if $\Sigma\left(\mathrm{A}_{0}^{\prime} . \mathrm{E}_{i}\right) \alpha_{i}=\mathrm{o}$ in $\mathrm{H}_{1}(\mathrm{M})$.

Proof. $-\Sigma\left(\mathrm{A}_{0}^{\prime} . \mathrm{E}_{i}\right) \alpha_{i}=\mathrm{o}$ if and only if there are integers $k_{j}$ such that

$$
\left(\mathrm{A}_{0}^{\prime} \cdot \mathrm{E}_{i}\right)=\Sigma k_{j}\left(\mathrm{E}_{j} \cdot \mathrm{E}_{i}\right),
$$

i.e. if the relation $\Sigma\left(\mathrm{A}_{0}^{\prime} . \mathrm{E}_{i}\right) \alpha_{i}=0$ is an integral sum of the relations defining $\mathrm{H}_{1}(\mathrm{M})$. But this is equivalent to $\left(\mathrm{A}_{0}^{\prime}+\Sigma k_{j} \mathrm{E}_{j} . \mathrm{E}_{i}\right)=\mathrm{o}$ for all $i$, i.e. $\mathrm{A}^{\prime}=\mathrm{A}_{0}^{\prime}+\Sigma k_{j} \mathrm{E}_{j}, k_{j}$ integral. Q.E.D.

The element $\Sigma\left(\mathrm{A}_{0}^{\prime} . \mathrm{E}_{i}\right) \alpha_{i}$ has this simple interpretation: if M is chosen near enough to P , it represents the I -cycle $\mathrm{A} \cap \mathrm{M}$. We see that this is again the fundamental map: (Group of Local Divisors at P ) $\rightarrow \mathrm{H}_{1}(\mathrm{M})$ considered in the final corollary of part (a). By the results of part (a), moreover, we can interpret (vi) as saying: $\mathrm{A}^{\prime}$ is integral if and only if A is locally analytically equivalent to zero (i.e. A is in the connected component of $\operatorname{Pic}(\mathbf{P})$ ). Essentially, our definition of intersection multiplicity on a normal surface is the unique linear theory that has the correct limiting properties for divisors that can be analytically deformed off the singular points.

## III. - THE CASE $\pi_{1}(\mathrm{M})=(e)$

We shall prove the following theorem, stronger than that announced above:
Theorem. - Let F be a non-singular surface, and $\mathrm{E}_{i}, i=\mathrm{I}, 2, \ldots, n$, a connected collection of non-singular curves on F , such that $\mathrm{E}_{i} \cap \mathrm{E}_{j}$ is empty, or consists of one point on a transversal intersection, and $\mathrm{E}_{i} \cap \mathrm{E}_{j} \cap \mathrm{E}_{k}$ is always empty. Let M be a tubular neighborhood of $\mathrm{UE}_{i}$, as defined in section I. If $(a) \pi_{1}(\mathrm{M})=(e)$, and $(b)\left(\left(\mathrm{E}_{i} . \mathrm{E}_{j}\right)\right)$ is negative definite, then $U \mathrm{E}_{i}$ is exceptional of first kind, i.e. is the total transform of some simple point on a surface dominated by F and birational to it.

Proof. - As above, $\pi_{1}(\mathbf{M})=(e)$ implies that all $\mathrm{E}_{i}$ are rational, and connected together as a tree. Now suppose that $\mathrm{UE}_{i}$ is not exceptional of first kind. Assume that among all collections of $\mathrm{E}_{i}$ with all the properties of the theorem, there is no collection not exceptional with fewer curves $\mathrm{E}_{i}$. As a consequence, no $\mathrm{E}_{i}$ of our collection has the two properties $(a)\left(\mathrm{E}_{i}^{2}\right)=-\mathrm{I},(b) \mathrm{E}_{i}$ intersects at most two other $\mathrm{E}_{j}$. For if it did, one could shrink $\mathrm{E}_{i}$ by Castelnuovo's criterion, preserving all the properties required (that the negative definiteness is preserved is clear as follows: the self-intersection of a cycle of the $\mathrm{E}_{j}$ 's on the blown down surface equals the self-intersection of its total transform on F which must be negative). We allow the case where there is only one $\mathrm{E}_{i}$. Now the central fact on which this proof is based is the following group-theoretic proposition:

Proposition. - Let $\mathrm{G}_{i}, i=\mathrm{I}, 2,3$, be non-trivial groups, and $a_{i}$ an element of $\mathrm{G}_{i}$. Then denoting the free product of A and B by $\mathrm{A} * \mathrm{~B}$, it follows $\mathrm{G}_{1} * \mathrm{G}_{2} * \mathrm{G}_{3} /$ modulo ( $a_{1} a_{2} a_{3}=e$ ) is non-trivial.

Proof. - First of all, if $\infty \geq n_{1}, n_{2}, n_{3}>\mathrm{I}$, then $\mathrm{Z}_{n_{1}} * \mathrm{Z}_{n_{2}} * \mathrm{Z}_{n_{3}} /\left(a_{1} a_{2} a_{3}=e\right)$ is non-trivial, where $\mathrm{Z}_{k}$ denotes the integers modulo $k$, and each $a_{i}$ is a generator. For, as a matter of fact, these are well-known groups easily constructed as follows: choose a triangle with angles $\pi / n_{1}, \pi / n_{2}$, and $\pi / n_{3}$ (modular if some $n_{i}=\infty$ ), in one of the three standard planes. Reflections in the three sides of the triangle generate a group of motions of the plane, and the group we seek is the subgroup, of index 2 , of the orientation preserving motions in this group. Secondly, reduce the general statement to this case by means of:
(\#) If $n=$ order of $a_{1}$ in $\mathrm{G}_{1}$, and $a_{1}$ is identified to a generator of $\mathrm{Z}_{n} \subseteq \mathrm{G}_{1}$, then $\mathrm{G}_{1} * \mathrm{G}_{2} * \mathrm{G}_{3} /\left(a_{1} a_{2} a_{3}=e\right)$ trivial $\Rightarrow \mathrm{Z}_{n} * \mathrm{G}_{2} * \mathrm{G}_{3} /\left(a_{1} a_{2} a_{3}=e\right)$ trivial.

To show this, let $\mathrm{H}=\mathrm{G}_{2} * \mathrm{G}_{3} /\left(\left(a_{2} a_{3}\right)^{n}=e\right)$, and note that H is isomorphic to $\mathrm{Z}_{n} * \mathrm{G}_{2} * \mathrm{G}_{3} /\left(a_{1} a_{2} a_{3}=e\right)$. Let $n^{\prime}$ be the order of $a_{1}$ in H . Then $\mathrm{G}_{1} * \mathrm{G}_{2} * \mathrm{G}_{3} /\left(a_{1} a_{2} a_{3}=e\right)$ is the free product of $\mathrm{G}_{1} /\left(a_{1}^{n^{\prime}}=e\right)$ and H with amalgamation of the subgroups generated by $a_{2} a_{3}$ and $a_{1}^{-1}$. But by O. Schreier's construction of amalgamated free products (see [5], p. 29) this is trivial only if H is, hence (\#). Now the proposition is trivial if any $a_{i}=e$; hence let $n_{i}=\operatorname{order}\left(a_{i}\right)>\mathrm{I}$. By (\#) iterated, $\mathrm{G}_{1} * \mathrm{G}_{2} * \mathrm{G}_{3} /\left(a_{1} a_{2} a_{3}=e\right)$ trivial implies $\mathrm{Z}_{n_{1}} * \mathrm{Z}_{n_{2}} * \mathrm{Z}_{n_{3}} /\left(a_{1} a_{2} a_{3}=e\right)$ trivial, which is absurd. Q.E.D.

Returning to the theorem, we wish to show the absurdity of $\pi_{1}(\mathrm{M})=(e)$, while no $\mathrm{E}_{i}$ is such that (a) $\left(\mathrm{E}_{i}^{2}\right)=-\mathrm{I}$, and (b) $\mathrm{E}_{i}$ meets at most two other $\mathrm{E}_{j}$. There are two cases to consider: either some $\mathrm{E}_{i}$ meets three or more other $\mathrm{E}_{j}$; or every $\mathrm{E}_{i}$ meets at most two other $\mathrm{E}_{j}$ (this includes the case of only one $\mathrm{E}_{\boldsymbol{i}}$ ).

Case 1. - Let $\mathrm{E}_{1}$ meet $\mathrm{E}_{2}, \ldots, \mathrm{E}_{m}$, where $m$ is at least 4. For $i=2,3, \ldots, m$, let $\mathrm{T}_{i}$ be the set of $\mathrm{E}_{j}$ 's (besides $\mathrm{E}_{1}$ ) such that $\mathrm{E}_{j}$ is connected to $\mathrm{E}_{i}$ by a series of $\mathrm{E}_{k}$ other than $\mathrm{E}_{1}$. The $\mathrm{T}_{i}$ 's are disjoint. Let $\mathrm{M}_{i}$ be the manifold bounding a neighborhood of $\mathrm{T}_{i}$ as above. Let $\mathrm{G}_{i}=\pi_{1}\left(\mathrm{M}_{i}\right)$, and $\mathrm{G}=\pi_{1}(\mathrm{M}) /$ modulo $\alpha_{1}=e$, where $\alpha_{1}$ represents, as in (I), the loop about $\mathrm{E}_{1}$. Then by the results of (I),

$$
\mathrm{G}=\mathrm{G}_{2} * \mathrm{G}_{3}, \ldots, * \mathrm{G}_{m} /\left(\alpha_{2} \alpha_{3} \ldots \ldots \alpha_{m}=e\right),
$$

if the $\mathrm{G}_{i}$ are ordered suitably, and $\alpha_{i}$ in $\mathrm{G}_{i}$ represents a loop about $\mathrm{E}_{i}$. Now $m \geq 4$, and $\pi_{1}(\mathrm{M})=(e)$, hence $\mathrm{G}=(e)$, hence by the above theorem, there exists an $i$ (say $i=2)$ such that $G_{2}=\pi_{1}\left(\mathrm{M}_{2}\right)=(e)$. By the induction assumption, the tree of curves $\mathrm{T}_{2}$ is exceptional of first kind. Therefore, by Zariski's theorem on the factorization of anti-regular transformations on non-singular surfaces (see [18]), some $\mathrm{E}_{j}$ in $\mathrm{T}_{2}$ enjoys the properties (a) and (b) with respect to $\mathrm{T}_{2}$. Then $\mathrm{E}_{j}$ would also enjoy them in $\mathrm{UE}_{i}$ (which is impossible) unless $\mathrm{E}_{j}=\mathrm{E}_{2}$, in which case $\mathrm{E}_{j}$ could meet only two other $\mathrm{E}_{k}$ (say $\mathrm{E}_{m+1}, \mathrm{E}_{m+2}$ ) in $\mathrm{T}_{2}$, but would meet three other $\mathrm{E}_{k}$ in $\mathrm{UE}_{i}$. Pursuing this further, apply the same reasoning to the curve $\mathrm{E}_{2}$ which meets exactly three other $\mathrm{E}_{k}$. Again, either some curve shrinks, or else either $\mathrm{E}_{1}, \mathrm{E}_{m+1}$, or $\mathrm{E}_{m+2}$ has in any case property (a), i.e. self-intersection - I. But then compute $\left(\left(\mathrm{E}_{2}+\mathrm{E}_{i}\right)^{2}\right)(i=\mathrm{I}, m+\mathrm{I}$, or $m+2$ according as which $\mathrm{E}_{i}$ has property (a)), and we get o , contradicting negative definiteness of the intersection matrix.

Case 2. - It remains to consider the case where no $\mathrm{E}_{i}$ intersects more than two others. Then the $\mathrm{E}_{i}$ are arranged as follows:

Fig. 3

In this case, it is immediate that $\pi_{1}$ is commutative, hence $=\mathrm{H}_{1}$. It is given (in additive notation) by the equations:

$$
\begin{aligned}
k_{1} \alpha_{1}-\alpha_{2} \ldots \ldots \ldots \ldots & =0 \\
-\alpha_{1}+k_{2} \alpha_{2}-\alpha_{3} \ldots \ldots & =0 \\
-\alpha_{2}+k_{3} \alpha_{3} \ldots \ldots & =0 \\
\cdots \cdot \alpha_{n-1}+k_{n} \alpha_{n} & =0
\end{aligned}
$$

where $k_{i}=-\left(\mathrm{E}_{i}^{2}\right)$. Assume all $k_{i} \geq 2$, and prove
hence the equations have a solution $\bmod \mu$. To show this, use induction on $n$, using the stronger induction hypothesis $k_{1}>1, k_{2}, \ldots, k_{n} \geq 2$, allowing $k_{i}$ to be rational. Then note the identity:

$$
\operatorname{det}\left(\begin{array}{ccccc}
k_{1} & -\mathrm{I} & \mathrm{o} & \ldots & \mathrm{o} \\
-\mathrm{I} & k_{2} & -\mathrm{I} & \ldots & \mathrm{o} \\
\ldots & \ldots & \ldots & \ldots & \ldots
\end{array}\right)=k_{1} \operatorname{det}\left(\begin{array}{cccc}
\left(k_{2}-\mathrm{I} / k_{1}\right) & -\mathrm{I} & \ldots & \mathrm{o} \\
-\mathrm{I} & k_{3} & \ldots & \mathrm{o} \\
\ldots \ldots & \ldots & \ldots & \ldots \\
\ldots & k_{n}
\end{array}\right)
$$

This completes the proof of our theorem.
Corollary. - P a normal point of an algebraic surface F. If F has a neighborhood U homeomorphic to a 4 -cell, P is a simple point of F .

Proof. - Let W be the intersection of an affine ball about P with F , as considered in the introduction, and so small that its boundary M lifted to a non-singular model $\mathrm{F}^{\prime}$ dominating F qualifies as a tubular neighborhood of the total transform of P . It suffices to show that $\pi_{1}(\mathbf{M})=(e)$, in view of the theorem just proven. Let $\mathrm{U}^{\prime}$ be a 4 -cellneighborhood of P contained in W , and let $\mathrm{W}^{\prime}$ be an affine ball about P contained in $\mathrm{U}^{\prime}$. We have constructed in section I a continuous map $\psi$ from $\mathrm{U}^{\prime}-(\mathrm{P})$ to M that
induces the canonical identification of M as the boundary of $\mathrm{W}^{\prime}$ to M (as the boundary of W). Therefore if $\gamma$ is any path in $M$, regard $\gamma$ as a path in the boundary of $\mathrm{W}^{\prime}$; as a path in $\mathrm{U}^{\prime}-(\mathrm{P})$ (which is homotopic to a 3 -sphere) it can be contracted to a point; but then $\psi$ maps this homotopy to contraction of $\gamma$ as a path in M. Q.E.D.

## IV. - AN EXAMPLE

It is instructive to note that there exist singular points $P$, for which $H_{1}(M)=(o)$, while, of course, $\pi_{1}(\mathbf{M}) \neq(e)$. Take P to be the origin of the equation $0=x^{p}+y^{q}+z^{n}$, where $p, q$, and $n$ are pairwise relatively prime. Look at the equation as $-(z)^{n}=x^{p}+y^{q}$; this shows that M is an $n$-fold cyclic covering of the 3 -sphere $|x|^{2}+|y|^{2}=\mathrm{I}, x, y$ complex, branched along the points $x^{p}+y^{q}=0$, i.e. along a torus knot, K, in $\mathrm{S}^{3}$. Therefore M is a manifold of the type considered by M. Seifert [20], p. 222; he shows $H_{1}(M)=(0)$.

The singular point $0=x^{2}+y^{3}+z^{5}$ is of particular interest as illustrating the possibility of a singular point on a surface whose local analytic Picard Variety is trivial contrary to a conjecture of Auslander. To show $\operatorname{Pic}(P)(P=(o, o, o))$, is trivial amounts to showing $\left(\mathrm{R}^{1} \pi\right)(\Omega)_{\mathrm{P}}=(\mathrm{o})$, where $\pi: \mathrm{F}^{\prime} \rightarrow \mathrm{F}$ is the map from a non-singular model to $\mathrm{o}=x^{2}+y_{\mathrm{a}}^{3}+z^{5}$ (since we know $\mathrm{H}_{1}(\mathrm{M})=(\mathrm{o})$ already). Let us choose a slightly better global surface F (our statement being local, we are free to choose a different model of $k(\mathrm{~F})$ outside a neighborhood of P$)$ : namely take $\mathrm{F}_{0}$ to be the double plane with sextic branch locus B : $u\left(u^{2} y^{3}+z^{5}\right)$, where $u, y, z$ are homogeneous coordinates. $\mathrm{F}_{0}$ has two singularities: one is over $y=z=0$ and this is P ; the other is over $u=z=0$ - call it $Q$. Let $F_{1}$ be the result of resolving $Q$ alone, and $F_{2}$ be the non-singular surface obtained by resolving P and Q . Let $\pi: \mathrm{F}_{2} \rightarrow \mathrm{~F}_{1}$. We must show $\left(\mathrm{R}^{1} \pi\right)\left(\Omega_{\mathrm{F}_{2}}\right)_{\mathrm{P}} \simeq(\mathrm{o})$. But since $\left(\mathrm{R}^{1} \pi\right)\left(\Omega_{\mathrm{F}_{2}}\right)$ is (o) outside of P , it is equivalent to show $\mathrm{H}^{0}\left(\mathrm{~F}_{1},\left(\mathbf{R}^{1} \pi\right)\left(\Omega_{\mathrm{F}_{2}}\right)\right)=(\mathrm{o})$. First of all, note that $\mathrm{F}_{2}$ is birational to $\mathrm{P}^{2}$ : indeed $\mathrm{o}=x^{2}+y^{3}+z^{5}$ is uniformized by the substitution:

$$
x=\mathrm{I} / u^{3} v^{5}(u+v)^{7}, y=-\mathrm{I} / u^{2} v^{3}(u+v)^{5}, z=-\mathrm{I} / u v^{2}(u+v)^{3} .
$$

Therefore $o=H^{1}\left(\mathrm{~F}_{2}, \Omega_{\mathrm{F}_{3}}\right)=\mathrm{H}^{2}\left(\mathrm{~F}_{2}, \Omega_{\mathrm{F}_{2}}\right)$. Now consider the Spectral Sequence of Composite Functors:

$$
\mathrm{H}^{i}\left(\mathrm{~F}_{1},\left(\mathrm{R}^{i} \pi\right)\left(\Omega_{\mathrm{F}_{2}}\right)\right) \Rightarrow \mathrm{H}^{k}\left(\mathrm{~F}_{2}, \Omega_{\mathrm{F}_{2}}\right) .
$$

Noting that $\left(\mathrm{R}^{0} \pi\right)\left(\Omega_{\mathrm{F}_{3}}\right)=\Omega_{\mathrm{F}_{1}}$, it follows:
a) $\mathrm{H}^{1}\left(\mathrm{~F}_{1}, \Omega_{\mathrm{F}_{1}}\right)=(\mathrm{o})$
b) $d_{2}^{0,1}: \mathrm{H}^{0}\left(\mathrm{~F}_{1},\left(\mathrm{R}^{1} \pi\right)\left(\Omega_{\mathrm{F}_{2}}\right)\right) \rightarrow \mathrm{H}^{2}\left(\mathrm{~F}_{1}, \Omega_{\mathrm{F}_{1}}\right)$
is $\mathrm{I}-\mathrm{I}$, onto.
Therefore, it suffices to show $\mathrm{H}^{2}\left(\mathrm{~F}_{1}, \Omega_{\mathrm{F}_{1}}\right)=(\mathrm{o})$, or $\mathrm{o} \geqslant p_{a}\left(\mathrm{~F}_{1}\right)\left(=\operatorname{dim} \mathrm{H}^{2}-\operatorname{dim} \mathrm{H}^{1}\right)$. Now unfortunately $p_{a}\left(\mathrm{~F}_{0}\right)=\mathrm{I}$, since, in general, if G is a double plane with branch locus of order $2 m, p_{a}(\mathrm{G})=(m-1)(m-2) / 2$ (none of the singularities of G being resolved,
of course) ( ${ }^{1}$. To compute $p_{a}\left(\mathrm{~F}_{1}\right)$, embed $\mathrm{F}_{0}$ in a family of double planes $\mathrm{F}_{0, \alpha}$, where the branch locus $B_{\alpha}$ for $F_{0, \alpha}$ is

$$
u\left(u^{2} y^{3}+z^{5}+\alpha u^{4} z\right)
$$

Now $\mathrm{F}_{0, \alpha}$ have singularities over $u=z=0$ of identical type for all $\alpha$, hence one may resolve these, and obtain a family of surfaces $F_{1, \alpha}$ containing $F_{1}$. But since $B_{\alpha}$, for general $\alpha$, has no singularity except $u=z=0$, the general $\mathrm{F}_{1, \alpha}$ is non-singular. Now by the invariance of $p_{a}[2 \mathrm{I}], \quad p_{a}\left(\mathrm{~F}_{1}\right)=p_{a}\left(\mathrm{~F}_{1, \alpha}\right) \leqslant \operatorname{dim} \mathrm{H}^{2}\left(\mathrm{~F}_{1, \alpha}, \Omega\right)=\operatorname{dim} \mathrm{H}^{0}\left(\mathrm{~F}_{1, \alpha}, \Omega(\mathrm{~K})\right), \mathrm{K}$ the canonical class on $\mathrm{F}_{1, \alpha}$. But if $\omega$ is the double quadratic differential (i.e. of type $\mathrm{A}\left(d x_{\wedge} d y\right)^{2}$ locally) on $\mathrm{P}^{2}$ with poles exactly at $\mathrm{B}_{\alpha}$, one can readily compute $\left(f_{\alpha}^{*} \omega\right)$, where $f_{\alpha}: \mathrm{F}_{1, \alpha} \rightarrow \mathrm{P}^{2}$; it turns out strictly negative, and as it represents 2 K , it follows

$$
p_{g}\left(\mathrm{~F}_{1, \alpha}\right)=\operatorname{dim} \mathrm{H}^{0}\left(\mathrm{~F}_{1, \alpha}, \Omega(\mathrm{~K})\right)=\mathrm{o} .
$$

For details on the behaviour of $p_{a}$ of double planes, which include our result as a particular case, see the works of Enriques and Campedelli cited in [4], p. 203-4, and the doctoral thesis of M. Artin [Harvard, I96o].

[^4]
[^0]:    $\left.{ }^{(1}\right) \mathrm{M}$ is, of course, not a fibre space in the usual sense. However, the map $\varphi_{*}$ in question is onto for any simplicial map such that the inverse image of every point is connected.

[^1]:    ${ }^{(1)}$ For example, proceeding surface by surface in any order, we may deform the complex $\mathrm{UE}_{\boldsymbol{i}}$ so that all the $\mathbf{E}_{\boldsymbol{j}}$ which meet some one $\mathrm{E}_{\boldsymbol{i}}$ meet it at the same point.

[^2]:    ${ }^{(1)}$ In the map $\mathrm{H}_{1}\left(\mathrm{E}_{i}^{*}\right) \rightarrow \mathrm{H}_{1}\left(\mathrm{E}_{i}\right)$, the kernel is generated by $\left\{\partial\left(\mathrm{U}_{i j}\right)\right\}$ with the single relation $\Sigma_{j \neq i} \partial\left(\mathrm{U}_{i j}\right)=$ $\partial$ (fundamental 2-cycle of $\left.\mathrm{E}_{i}^{*}\right) \sim 0$.

[^3]:    ${ }^{(1)}$ The composition law is the "Kronecker" product treated so elegantly by Hermann Weyl [12], cf. chapter 2, namely:

    $$
    \begin{gathered}
    (\mathfrak{a}, \mathfrak{b}) \rightarrow \text { rank } 1 \text { component of } \mathfrak{a} \cdot \mathfrak{b} \\
    =\bigcup_{n=1}^{\infty}(\mathfrak{a} \cdot \mathfrak{b}): \mathfrak{m}^{n}
    \end{gathered}
    $$

    where $\mathfrak{m}=$ maximal ideal of $\mathfrak{o}$
    $(:)=$ residual quotient operation.

[^4]:    ${ }^{(1)}$ This may be seen by means of a suitable resolution of $\left(\mathrm{R}^{0} f\right)\left(\Omega_{\mathrm{G}}\right), f: \mathrm{G} \rightarrow \mathrm{P}^{\mathbf{2}}$ being its double covering. It is, however, classical: cf. [4], p. 180-2 using the formula:

    $$
    \begin{aligned}
    & 4 p_{a}=n+\mathrm{P}-3 \pi-k / 3-2 \text { where } n=2, k=0, \\
    & \pi=m-1, \text { and } \\
    & \mathrm{P}=(2 m-1)(2 m-2) / 2=p_{a}(\text { Branch Locus }) .
    \end{aligned}
    $$
