A Link Between C^∞ and Analytic Solvability for P.D.E. with Constant Coefficients.

GIUSEPPE ZAMPIERI (*)

0. Let Ω be an open set of \mathbf{R}^n and $P(= P(D))$ a linear partial differential operator with constant coefficients; Hörmander and Malgrange proved that:

$$(1) \quad PC^\infty(\Omega) = C^\infty(\Omega),$$

if and only if Ω is P -convex in the sense of the following definition:

- (2) Ω is P -convex if to every compact set $K_0 \subset \Omega$ there exists another compact set $K \subset \Omega$ s.t. $g \in C_c^\infty(\Omega)$ and $\text{supp } P(-D)g \subset K_0$ implies $\text{supp } g \subset K$.

Of course (2) is not necessary to get $PC^\infty(\Omega') \supset r_{\Omega'}^\Omega C^\infty(\Omega)$ (where $r_{\Omega'}^\Omega$ denotes the restriction map from Ω to Ω') for every relatively compact open set Ω' of Ω , because every differential operator with constant coefficients is semiglobally solvable in view of the existence of the fundamental solution. Denoting by $A(\Omega)$ the space of the real analytic functions on Ω , we prove here that (2) is also necessary in order to solve analytically the equations $Pu = f$, $\forall f \in A(\Omega)$, over compact subsets of Ω ; namely:

THEOREM 1. *Let Ω be an open subset of \mathbf{R}^n . If $PA(\Omega') \supset r_{\Omega'}^\Omega A(\Omega)$ for every relatively compact open subset Ω' of Ω , then $PC^\infty(\Omega) = C^\infty(\Omega)$.*

(*) Indirizzo dell'A.: Seminario Matematico dell'Università, via Belzoni 7, I 35100 Padova.

L'autore usufruisce di borsa di studio C.N.R. per l'Analisi Funzionale.

Since in our work [6] we proved that (1) is sufficient to have $PA(\Omega) = A(\Omega)$ when $\Omega \subset \mathbb{R}^2$, we can state:

THEOREM 2. *Let Ω be an open set of \mathbb{R}^2 ; $PA(\Omega) = A(\Omega)$ if and only if $PC^\infty(\Omega) = C^\infty(\Omega)$.*

Note that if $n > 2$ the result isn't generally true. Indeed in [4] Hörmander proved that $PA(\mathbb{R}^n) \neq A(\mathbb{R}^n)$ unless every irreducible germ of the real characteristic asymptotic variety $\{x \in \mathbb{R}^n \sim 0: P_m(x) = 0\}$ (where P_m is the principal part of P) is of dimension $n - 1$. For the heat equation in \mathbb{R}^3 the real characteristics form a line from which follows the nonsurjectivity of the heat operator thought as endomorphism of $A(\mathbb{R}^3)$; this explains a conjecture by E. De Giorgi and L. Cattabriga [1] which L. Piccinini first proved.

1.

We need some preliminary information. We call $(\mathcal{L}\mathcal{F})$ -space every Hausdorff T.V.S. which is the union of an increasing sequence $\{A_i\}_i$ of (\mathcal{F}) -spaces, the imbedding of E_i into E_{i+1} being continuous, endowed with the inductive limit topology of E_i . We call strictly bornological space every Hausdorff space which is the inductive limit of a family of Banach spaces. It is easy to see that every Hausdorff quasi-complete space is strictly bornological if (and only if) it is bornological. That said, if E is a strictly bornological space and F a $(\mathcal{L}\mathcal{F})$ space, every linear map of E into F is continuous if and only if it has closed graph (see [2] pg. 271).

Let x be the variable in \mathbb{R}^n and (x, t) that in \mathbb{R}^{n+1} ; consider \mathbb{R}^n as a subset of $\tilde{\mathbb{R}}^{n+1}$ where $\tilde{\mathbb{R}}^{n+1}$ is the Alexandroff compactification of \mathbb{R}^{n+1} . Let Ω be a subset of \mathbb{R}^n not necessary open, set $A(\Omega) = \varinjlim A(B)$ (in the algebraic sense) where B varies in the family of the open sets of \mathbb{R}^n containing Ω which are connected with Ω ; $\forall f \in A(\Omega)$ there is one and only one harmonic symmetric (with respect to \mathbb{R}^n) function $\tilde{f}(x, t)$ in an open symmetric neighbourhood of Ω in $\tilde{\mathbb{R}}^{n+1}$ s.t. $\tilde{f}(x, 0) = f(x) \forall x$ in an open neighbourhood of Ω in \mathbb{R}^n . So we algebraically and topologically identify the space $A(\Omega)$ with $\varinjlim \mathcal{A}_s(B)$ when B varies in the family of symmetric neighbourhoods of Ω in $\tilde{\mathbb{R}}^{n+1}$ and $\mathcal{A}_s(B)$ denotes the (\mathcal{F}) -space of the harmonic symmetric functions on B (that are infinitesimal at ∞ when $\infty \in B$). One can prove that $A(\Omega) = \varprojlim A(K)$ with K varying in the family of

compact subsets of Ω ; with such a topology, $A(\Omega)$ is a Hausdorff complete barreled bornological (and so strictly bornological) space and, if Ω is a compact set, a (\mathcal{LF}) -space. Denoting by $A'(\Omega)$ the dual of $A(\Omega)$ there is an algebraic and topological isomorphism:

$$\Psi: A'(\Omega) \rightarrow \mathcal{A}_s(\overset{\circ}{\mathbb{R}^{n+1}} \sim \Omega)$$

defined as follows: if $(x, t) \in \overset{\circ}{\mathbb{R}^{n+1}} \sim \Omega$ and $T \in A'(\Omega)$; $\Psi T(x, t) = \langle T_\xi, E(x - \xi, t) \rangle$ where E is the fundamental solution of Δ in \mathbb{R}^{n+1} infinitesimal at ∞ ; precisely $E(x, t) = \alpha/|(x, t)|^{n-1}$ (here we suppose $n \geq 2$) with α suitable constant. One obtains ΨT on a neighbourhood of $\overset{\circ}{\mathbb{R}^{n+1}} \sim \Omega$ by means of an analytic continuation. Such an identification enables us to say that every analytic functional has compact support and that the polynomials are dense in $A(\Omega) \forall \Omega \subset \mathbb{R}^n$ ⁽¹⁾.

2.

PROF OF THEOREM 1. Given a generic function $g \in C_c^\infty(\Omega)$ we associate to g the linear functional on $A(\Omega)$ defined by:

$$\langle T_g, f \rangle = \int gf dx \quad \forall f \in A(\Omega).$$

T_g is continuous on $A(\Omega)$ for the seminorm:

$$f \rightarrow \sup_{x \in \text{supp } g} |f(x)| \quad f \in A(\Omega)$$

is continuous on $A(\Omega)$. First we prove that $\text{supp } g = \text{supp } T_g$, where $\text{supp } T_g$ is the smallest compact set of \mathbb{R}^n s.t. $T_g \in A'(\text{supp } T_g)$ or equivalently the smallest compact set of \mathbb{R}^{n+1} on the complement of which ΨT_g has a harmonic continuation (Ψ is the representing isomorphism of $A'(\Omega)$). Indeed observe that:

$$\Psi T_g(x, t) = \int \frac{\alpha g(\xi)}{|(\xi - x, t)|^{n-1}} d\xi = g \otimes \delta_t * E(x, t) \quad \forall (x, t) \in \mathbb{R}^{n+1} \sim \bar{\Omega}.$$

Since $g \otimes \delta_t * E$ is continuous in \mathbb{R}^{n+1} because it is the newtonian

(1) For more information see [5].

potential of the masses with density g , it follows that $\mathcal{P}T_\sigma(x, t) = g \otimes \delta_t * E(x, t) \forall (x, t) \in \mathbb{R}^{n+1} \sim \text{supp } T_\sigma$. Finally $\text{supp } T_\sigma$ is the support, in \mathbb{R}^{n+1} , of the distribution $\Delta(g \otimes \delta_t * E) = g \otimes \delta_t$ or equivalently it is the support, in \mathbb{R}^n , of g . We want to prove now that the distances from $\mathbb{R}^n \sim \Omega$ to $\text{supp } T_\sigma$ and to $\text{supp } {}^tPT_\sigma$ (2), which obviously coincides with $\text{supp } T_{P(-D)\sigma}$, are equal. Let Ω_n be the open set of all $x \in \Omega$ s.t. $|x| < n$ and the distance from x to $\mathbb{R}^n \sim \Omega$ is larger than $1/n$ and note that there is a n_0 s.t., $\forall n \geq n_0, T_\sigma \in A'(\Omega_n)$. Fix a n among them and set $d(\text{supp } {}^tPT_\sigma, \mathbb{R}^n \sim \Omega) = d$; consider $\forall y \in \mathbb{R}^n$ s.t. $|y| < \inf\{d - 1/n, n\}$ the functional $\tau_y {}^tPT_\sigma$ where τ_y is the translation operator by means of y . Obviously $\tau_y {}^tPT_\sigma$ has its support in Ω and moreover belongs to ${}^tPA'(\Omega_{2n})^-$ (weak closure). In fact, for every fixed $f \in A(\Omega_{2n})$ s.t. $Pf = 0$, the map:

$$y \mapsto \langle \tau_y {}^tPT_\sigma, f \rangle \quad \forall |y| < \inf\{d - 1/n, n\}$$

is analytic and, since it vanishes with all its derivatives at $y = 0$, it is identically zero. So $\forall |y| < \inf\{d - 1/n, n\} {}^tPT_\sigma \in {}^tPA'(\tau_y \Omega_{2n})^-$; and, since by hypothesis $PA(\tau_y \overline{\Omega_{2n}}) \supset r_{\tau_y \overline{\Omega_{2n}}}^{\tau_y \Omega} A(\tau_y \Omega)$, it follows that there is some $T^y \in A'(\tau_y \Omega)$ s.t. ${}^tPT_\sigma = {}^tPT^y$. In fact consider the (commutative) diagram:

$$\begin{array}{ccc} A(\tau_y \overline{\Omega_{2n}}) & \xrightarrow{P} & A(\tau_y \overline{\Omega_{2n}}) \\ \uparrow r_{\tau_y \overline{\Omega_{2n}}}^{\tau_y \Omega} & & \uparrow r_{\tau_y \overline{\Omega_{2n}}}^{\tau_y \Omega} \\ A(\tau_y \Omega) & \xrightarrow{P} & A(\tau_y \Omega) \end{array}$$

The space $A(\tau_y \overline{\Omega_{2n}})$ is of type (\mathcal{LF}) because $\overline{\Omega_{2n}}$ is a compact set, while $A(\tau_y \Omega)$ is a strictly bornological space; so we can use the closed graph theorem as we saw in paragraph 1; thus we conclude that $PA(\tau_y \overline{\Omega_{2n}}) \supset r_{\tau_y \overline{\Omega_{2n}}}^{\tau_y \Omega} A(\tau_y \Omega)$ implies ${}^tPA'(\tau_y \overline{\Omega_{2n}})^- \subset {}^tPA'(\tau_y \Omega)$ (3).

Since, $\forall y, T_\sigma = T^y$ (indeed the map $P: A(\mathbb{R}^n) \rightarrow A(\mathbb{R}^n)$ has dense range because the polynomials are dense in $A(\mathbb{R}^n)$) it follows that $T_\sigma \in \bigcap_{|y| < \inf\{d - 1/n, n\}} A'(\tau_y \Omega)$.

(2) tP is the transpose of $P: A(\Omega) \rightarrow A(\Omega)$.

(3) See Theorem 2 of [7] and repeat step by step the demonstration of the analogous implication. Note that for spaces like $A(\Omega)$ and $A(\Omega_{2n})$ we couldn't obtain the same result since, Ω_{2n} being open, $A(\Omega_{2n})$ isn't an inductive limit of a sequence of (\mathcal{F}) -spaces.

Thus $d(\text{supp } T_\sigma, \mathbf{R}^n \sim \Omega) \geq \inf \{d - 1/n, n\}$ and, with n tending to ∞ $d(\text{supp } T_\sigma, \mathbf{R}^n \sim \Omega) \geq d$.

Summarizing we proved that $\forall g \in C_c^\infty(\Omega)$ $d(\text{supp } g, \mathbf{R}^n \sim \Omega) = d(\text{supp } P(-D)g, \mathbf{R}^n \sim \Omega)$ which obviously implies that Ω is P -convex.

q.e.d.

3. - Remark.

It is very easy to prove theorem 1 when Ω is a subset of \mathbf{R}^2 and P is homogeneous; to see this we'll use an idea suggested by prof. Bratti. If $PC^\infty(\Omega) \neq C^\infty(\Omega)$ we know there exists a characteristic line of P that intersects Ω in more than one interval; by change of the affine coordinate system we can suppose that such a line is the x_1 -axis (and so $P(D_{x_1}, D_{x_2}) = D_{x_1}R(D_{x_1}, D_{x_2})$) and that Ω contains an open subset

$$\Omega^0 = \Omega^1 \cup \Omega^2 \cup \Omega^3 \text{ s.t.:}$$

$$\Omega^1 = \{(x_1, x_2): -\varepsilon_1 < x_1 < \varepsilon_2, -c < x_2 < 0\};$$

$$\Omega^2 = \{(x_1, x_2): -\varepsilon_1 < x_1 < -a_1 < 0, -c < x_2 < d, d > 0\};$$

$$\Omega^3 = \{(x_1, x_2): 0 < a_2 < x_1 < \varepsilon_2, -c < x_2 < d\};$$

and the point $(0, 0) \notin \Omega$.

From the hypothesis $PA(\Omega') \supset r_{\Omega'}^0 A(\Omega)$, $\forall \Omega'$ relatively compact open subset of Ω , it follows that $D_{x_1}C^\infty(\Omega^0) \supset r_{\Omega^0}^0 A(\Omega)$. In fact given $f \in A(\Omega)$ and given, $\forall n$, $u_n \in A(\Omega_n^0)$ ⁽⁴⁾ s.t. $Pu_n = f$ in Ω_n^0 then $R(u_{n+1} - u_n)$ is analytic in Ω_n^0 and since it verifies there

$$D_{x_1}R(u_{n+1} - u_n) = 0,$$

it has an analytic extension on the convex hull of Ω_n^0 . Since the C^∞ solutions in \mathbf{R}^2 of $D_{x_1}u = 0$ are dense in the space of the C^∞ solutions in convex regions of the same equation, we can use the well known device of the telescopic series to find a function $u \in C^\infty(\Omega^0)$ which resolves $D_{x_1}u = f$. But such a solution u can't exist when the datum f

(4) Ω_n^0 is the subset of Ω^0 defined in the proof of theorem 1.

is $1/(x_1^2 + x_2^2)$; in fact if it existed we would have, in Ω^1 :

$$u(x_1, x_2) = 1/x_2 \operatorname{arctg}(x_1/x_2) + u(0, x_2).$$

This gives $\lim_{x_1 \rightarrow 0^-} u(0, x_2) = +\infty = -\infty$.
